Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Since December 2019, a novel coronavirus disease 2019 (COVID-19) caused by a novel coronavirus, SARS-CoV-2, has been emerging in Wuhan, Hubei Province, China.1 It has spread to other areas of China and further to more than 40 countries and regions around the world.2 In Singapore, Japan, Korea, Italy, and Thailand, there have been community-based infections. A few cases of pneumonia in children with SARS-CoV-2 infection were reported. Pediatric cases are mainly family cluster cases, and most of them have epidemiological links to adult patients. Pediatric clinical manifestations are not typical, and relatively milder, compared with that of adult patients.

2. Clinical manifestations of SARS-CoV-2 in children

Children with COVID-19 infection may be asymptomatic or have fever, dry cough, and fatigue, with a few upper respiratory symptoms, including nasal congestion and runny nose;7 some patients have gastrointestinal symptoms, including abdominal discomfort, nausea, vomiting, abdominal pain, and diarrhea. Most infected children have mild clinical manifestations, and the prognosis is good. Most of the pediatric patients have recovered within 1–2 weeks after onset. It is very uncommon to progress to lower respiratory tract infections. Data from adults showed that severe cases tend to have difficulty breathing 1 week after the onset of the disease.3 Severe cases can progress to acute respiratory distress syndrome, septic shock, refractory metabolic acidosis, and coagulation dysfunction,
but such severity is rare in children. The first pediatric critically ill patient was reported from Wuhan Children’s Hospital. The 1-year-old boy was admitted because of intermittent diarrhea, vomiting for 6 days, and fever with shortness of breath for half a day. On the second and the seventh days of admission, the pharyngeal swab SARS-CoV-2 nucleic acid test was negative, but the test was positive on the eighth day. The child’s chest radiographs showed pneumonia in the right lung on the day of admission. The child was immediately sent to the intensive care unit and intubated. The patient’s condition improved and was successfully weaned off from the ventilator on the 10th day of admission. The patient eventually recovered fully. From the report, it is apparent that children remain susceptible to the infection, and severe infection could occur.

3. Clinical characteristics of infants and newborns with SARS-CoV-2 infection

Although COVID-19 cases were rare in infants and newborns, nine hospitalized infants diagnosed with COVID-19 in China from December 8, 2019, to February 6, 2020, were reported. The minimum age was 1 month and the maximum 11 months. Of the nine infants, four had fever, two mild upper respiratory symptoms, one asymptomatic, and two no information on symptoms. The time between admission and diagnosis was 1–3 days. All nine babies had at least one infected family member, and the baby’s infection usually occurred after the family member’s infection. All nine infants did not require intensive care or mechanical ventilation and had no serious complications. The small number of SARS-CoV-2-infected infants may be due to the possible low risk of exposure to the virus or to mild or asymptomatic diseases that cannot be fully identified.

Cases of neonatal infection with SARS-CoV-2 have been reported in China, with the youngest being 30 h after birth. However, a study of nine pregnant women with laboratory-confirmed COVID-19 pneumonia suggested that there is currently no evidence of intrauterine infection caused by vertical transmission from mother to child. Newborns may still acquire a SARS-CoV-2 infection through close contact with infected mothers. The diagnosis of SARS-CoV-2 neonatal infection should meet all of the following criteria: (1) at least one clinical symptom, including unstable body temperature, low activity or poor feeding, or shortness of breath, (2) chest radiographs showing abnormalities, including unilateral or bilateral milled glass opacities, (3) a SARS-CoV-2 infection diagnosis in the patient’s family or caregivers, and (4) close contact with people who may have or have confirmed SARS-CoV-2 infection, patients with unexplained pneumonia, or wild animals in the animal market or wild animals. All possible or laboratory-confirmed neonatal SARS-CoV-2 infections should be admitted to the neonatal intensive care unit. The efficacy of antiviral drugs is uncertain in children, and antimicrobial agents are only applicable to patients with possible or proven bacterial infections. If newborns also present with respiratory distress syndrome, administration of high-dose pulmonary surfactant, nitric oxide inhalation, and high-frequency oscillatory ventilation should be considered. In critically ill newborns, intravenous administration of glucocorticoids or immunoglobulins, sustainable kidney replacement, and extracorporeal membrane oxygenation may also be considered.

4. Conclusion

The current outbreak of COVID-19 remains severe in China and has been designated as a Public Health Emergency of International Concern by the WHO. SARS-CoV-2 is highly contagious. Although the number of reported pediatric patients is small at this point, children are vulnerable to the infection. The importance to increase awareness, reinforce infection control measures, and perform health management within the families can never be overemphasized.
