EXISTENCE OF ORBIFOLDS IV: EXAMPLES

PAUL FEIT

Abstract. This work concludes a series of four papers on the foundational theory of orbifolds and stacks. We apply the abstract theory, developed in its predecessors, to orbifolds derived from manifolds. Specifically, we show how the very concrete topological base spaces associated to such orbifolds can be described and manipulated in our universal language. At the same time, we interpret our many categorical axioms in several explicit contexts.

Introduction

In a series of works, the author has developed a Existence Criterion for categories of orbifolds. In this concluding paper, we offer applications of the abstract machinery. We begin with topological spaces relevant to orbifolds, and develop enough point-set theory to prove that the hypotheses of our universal propositions apply. We also give explicit meaning to their conclusions.

This paper owes much of its subject matter to Ms. Dorette Pronk, who, as of this writing, is preparing for her doctorate. The author’s original motivation arose from algebraic geometry. Specifically, our hope was to simplify and complete formulations for algebraic spaces and stacks. This starting point essentially forced a categorical perspective upon us. Ms. Pronk pointed out that there are many more accessible, geometric theories of orbifolds. She challenged us to explain certain empirical observations and practical questions in the context of our theory. This paper is, primarily, a series of answers to her questions. Some comments are complete, some are partial.

The contents are roughly as follows. We introduce a subcategory \textbf{Gen} of the category of topological spaces. To avoid problems with the axioms of set theory, we limit it as follows: for each set \( S \), we let \( \text{Gen}[S] \) be the subcategory of objects which have a cover by open subsets of cardinality less than or equal to the cardinality of \( S \). (When

Much of this paper and its predecessor was drafted during two summer visits to MSRI, Berkeley. Research at MSRI is supported in part by NSF Grant # DMS-9022140.
$S = IR$, the subcategory includes most standard objects of study.) This category is then examined from several perspectives.

(1.a) We assign to $\text{Gen}$ a pseudogeometric topology, and verify many abstract conditions discussed in previous papers. Actually, the majority of our universal constraints are translations of classical point-set ideas to the categorical level. Each individual identity is simple to check.

(1.b) A universal theorem from [4] now assigns to $\text{Gen}$ a pseudo´etale topology. That is, we assign to it a topology from which our plus construction creates orbifold-type objects. For technical reasons, it is convenient to restrict the topology to $\text{Gen}[S]$. (There are formal questions about $\text{Gen}$ which we conjecture to be resolvable.) The category $\text{Gen}[S]^+$ will contain our first explicit, non-trivial orbifolds. These include objects with mirrored boundaries and cone points, as discussed in [4].

(1.c) Although members of $\text{Gen}[S]$ have no differentiable or analytic structure, the explicit construction here has obvious analogues for a category of manifolds of any kind ($S = IR$). Consequently, our work shows to define pseudo´etale topologies for differential or analytic manifolds.

(1.d) Inside $\text{Gen}[S]$, we give examples of a group action $G$ on an object $M$ such that non-trivial members of $G$ have fixed points but, in the categorical sense of [4], the quotient map $q : M \rightarrow G \backslash M$ is Galois (ie., discrete, overlays absolutely and uniformly, etc.).

(1.e) Many classical orbifolds are regarded as some sort of a topological base space plus extra information. Our theory does not use sheaves of structure to model objects. We have an alternative perspective which allows for base spaces in contexts where they exist. In our language, to say that each object in a category $\mathcal{C}$ has a topological aspect is to assign to it a continuous functor $\Gamma : \mathcal{C} \rightarrow \text{Gen}[S]$ which is faithful. If $f$ and $g$ are distinct $\mathcal{C}$-morphisms between two objects, then $\Gamma(f)$ and $\Gamma(g)$ are continuous functions between “underlying” base spaces; moreover, if $\Gamma(f)$ and $\Gamma(g)$ agree as functions, then $f = g$ in $\mathcal{C}$. We prove that, under an elementary hypothesis, every lift of $\Gamma$ (ie., $\Gamma^+$, $(\Gamma^+)^+$, ...) is also faithful.

(1.f) Let $\mathcal{C}$ be a category which is being used to generate orbifolds (such as a category of manifolds of some type). Let $M, N \in \mathcal{C}$, and let $G$ and $H$ be groups with actions on $M$ and $N$, respectively. Then $G \backslash M$ and $H \backslash N$ exist in $\mathcal{C}^+$. What is a morphism
Throughout the paper, we use the notation, terminology and theorems of earlier works. We must assume that the reader is familiar with, or has access to these papers.

Section 1 defines the topological context Gen. (We emphasize certain subcategories, which will not be discussed in this introduction.) As hinted in previous works, a vital concept is that a theory of orbifold-type objects should begin with a topological category in which the class of morphisms is restricted. The definition of \textit{diffuse} continuous function requires some point-set topology.

We need topologies for Gen. Each object in Gen has a topology in the point-set sense. Our universal framework discusses topology, but in a categorical sense. Section 2 defines a \textit{pseudogeometric} topology for Gen. This amounts to (1) rewriting point-set concepts, like subsets and connectedness, in the abstract language and (2) verifying many categorical restrictions. Although numerous, each individual condition of our universal axiom set translates to an easy statement in the concrete situation.

The pseudogeometric topology is too elementary to generate orbifolds. In [6], a method for deriving a pseudo´etale topology from a pseudogeometric topology was introduced. It is the latter construct which, in unison with the plus functor, generates orbifold-type objects. It is the pseudo´etale topology that occupies the our attention for the rest of the paper.

Definition of the derived pseudo´etale is forbiddingly formal. However, we have developed an infrastructure of theory for the concept. Section 3 reviews what is known about pseudo´etale morphisms, and where there are gaps. We conjecture that some of the omissions can be resolved by further work. Other difficulties, such as the fact that Gen is not closed under descent, are part of the theory.

We seek a context in which there is a finite group $G$ acting on a manifold $M$ such that non-trivial members of $G$ have fixed points and yet the quotient map $q : M \rightarrow G\backslash M$ has many of the properties usually exhibited only by quotients for discrete actions. Those properties were discussed, at the level of categories, in [4]. We characterized particularly good quotients as being \textit{Galois}. Inside Gen, we can actually exhibit such group actions for the first time. In this context, the challenge is to find $G$ and $M$ for which the morphism $q$ is pseudo´etale. Theorem 19 gives an explicit hypothesis under which this occurs. It requires some effort to prove that theorem. Section 4 starts the proof with a study of fibered products in Gen. Then, Section 5 brings in
Section 3 changes topics. It focuses on the following issue:

(2) Suppose \( f \) and \( g \) are morphisms between two differentiable or analytic orbifolds of some kind. Assume that the underlying functions of \( f \) and \( g \) (that is, the continuous maps they determine between base spaces) agree. Show that \( f = g \).

We interpret (2) to state that the functor which sends an orbifold to its underlying topological space is faithful. We offer a hypothesis under which faithfulness of a topological model is preserved by the plus construction.

Section 4 interprets the abstract definition in an explicit context. Suppose \( G \) and \( H \) are groups which act, respectively, on affine objects \( M \) and \( N \) such that \( G\backslash M \) and \( H\backslash N \) exist as orbifold-type objects. There is a definition of morphism from \( G\backslash M \to H\backslash N \) in our theory. If \( M \) and \( N \) are both some type of manifold, then there exist topological quotients \( G\backslash M \) and \( H\backslash N \) which are quite explicit. This leads to a deceptive principle: an orbifold morphism \( F : M \to N \) factors to an orbifold morphism \( f : G\backslash M \to H\backslash N \) if and only if the underlying continuous function of \( F \) factors through the topological quotients. Mathematicians have discovered that this idea leads to contradictions. We illustrate the falsity of the principle by considering a pathology based on an example in Schwarz’s thesis [13].

The author is especially grateful to MSRI in Berkeley. Virtually all of this paper, and much of its predecessor, were drafted during visits to MSRI in the summers of 1993 and 1994. The staff helped to arrange a synchronous stay by Dorette Pronk, whose concerns motivate most of this paper.

1. Topological Terminology

Let \( \textbf{Top} \) be the category of topological spaces (in which the morphism class consists of all continuous functions). In the present paper, we define a space \( X \in \textbf{Top} \) to be \textit{locally connected} if each point has a basis consisting of connected neighborhoods. We do \textit{not} require that a locally connected space be Hausdorff. Let \( \textbf{LC} \) denote the class of locally connected topological spaces. Connected components are always closed; if \( X \in \textbf{LC} \), then its connected components are open as well. Denote the closure of a subset \( C \subseteq X \) by \( \overline{C} \).

Let \( X \in \textbf{Top} \). We say \( X \) is \textit{locally Hausdorff} if it has a cover by open subsets, each of which is Hausdorff in the subset topology. A class of locally Hausdorff objects will appear later.
Let $X \in \textbf{Top}$. By a subset element of $X$, we mean a pair $(U, I)$ where $U$ is an open subset of $X$ and $I$ is a subset of $U$. We call an element $(U, I)$ closed if $I$ is closed in $U$. Suppose $f : X \to Y$ is a continuous function between topological spaces. For $(U, I)$ a subset element of $Y$, define the subset element $f^{-1}(U, I)$, or pullback of $(U, I)$ along $f$, of $X$ to be $(f^{-1}U, f^{-1}I)$.

Now, we introduce some non-standard terminology.

**Definition 1.** Let $X \in \text{LC}$. An open subset $U$ of $X$ is called $Z$-dense (in $X$) if, for every non-empty open connected subset $C$ of $X$, $U \cap C$ is non-empty and connected. (One may regard these as a generalization of sets which are dense in a Zariski topology, as used in algebraic geometry.) A subset $I \subseteq X$ is called negligible (in $X$) if its complement is $Z$-dense.

The following comments are tautological consequences of the definition.

**Proposition 2.** Let $X \in \text{LC}$.

(A) A $Z$-dense subset is dense and open.

(B) The intersection of a finite family of $Z$-dense open subsets is a $Z$-dense open subset.

(C) Let $U, V \subseteq X$ be open subsets such that $U \subseteq V$. If $U$ is $Z$-dense, then $V$ is $Z$-dense.

(D) Let $U, V \subseteq X$ be open subsets such that $U \subseteq V$. If $V$ is $Z$-dense in $X$ and $U$ is $Z$-dense in $V$, then $U$ is $Z$-dense in $X$.

(E) Let $U, V \subseteq X$ be open subsets. If $U$ is $Z$-dense in $X$, then $U \cap V$ is a $Z$-dense open subset of $V$.

**Corollary 1.** Let $X \in \text{LC}$.

(A) A negligible subset of $X$ is closed and nowhere dense.

(B) The union of a finite family of negligible subsets of $X$ is negligible.

(C) A closed subset of a negligible set is negligible.

(D) Let $I$ be a negligible subset of $X$ and let $J$ be a negligible subset of $X - I$. Then $I \cup J$ is negligible in $X$.

(E) Let $I, V \subseteq X$ be subsets. If $V$ is open and $I$ is negligible in $X$, then $I \cap V$ is a negligible subset of $V$.

**Proof.** Part (C) of the Lemma requires the elementary fact that if $D$ is a connected subset of $X \in \textbf{Top}$, and if $D \subseteq E \subseteq \overline{D}$, then $E$ is connected. All other claims are tautological. $\square$
It is easy to find a local characterization of the property of being negligible.

**Lemma 3.** Let \( X \in \text{LC} \), and let \( I \subseteq X \) be a closed subset. Then the following two conditions are equivalent.

(3.a) For each \( x \in I \), there is a basis of neighborhoods \( \mathcal{V}_x \) at \( x \) such that, for each \( V \in \mathcal{V}_x \), both \( V \) and \( V - I \) are connected and non-empty.

(3.b) \( I \) is negligible in \( X \).

**Proof.** Obviously the problem is to prove (3.b) from (3.a). Hereafter, assume (3.a).

As a first step, observe that, trivially, \( I \) has no interior. We finish the proof by contradiction.

Let \( C \) be a connected, non-empty open subset of \( X \) for which \( C - I \) is not both connected and non-empty. By our first step, \( C - I \) must be a non-empty, disconnected set. Then there are two non-empty closed subsets \( A \) and \( B \) of \( C - I \) such that \( A \cap B = \emptyset \) and \( A \cup B = C - I \). Let \( A^* \) and \( B^* \) be the respective closures of \( A \) and \( B \) with respect to \( C \). Then \( A^* \cup B^* = C \), because \( I \) is nowhere dense. Since \( C \) is connected, there must be \( x \in A^* \cap B^* \). Clearly, \( x \in I \). Let \( V \in \mathcal{V}_x \) such that \( V \subseteq C \). Then \( V - I \) is connected and non-empty. Consequently, \( V - I \) intersects only one of the sets \( A, B \). Without loss of generality, assume \((V - I) \cap A = \emptyset \). Now \( V \cap A = (V - I) \cap A = \emptyset \). But, since \( x \) is in the closure of \( A \), the latter statement is impossible. \( \square \)

**Definition 4.** Let \( X \in \text{Top} \). A subset element \((U, I)\) is called negligible if, in the subset topology, \( U \in \text{LC} \) and \( I \) is a negligible subset of \( U \).

Let \( f : X \to Y \) be a continuous function between two locally connected spaces. We say \( f \) is diffuse if \( f \) pulls back each negligible subset element of \( Y \) to a negligible subset elements of \( X \).

**Corollary 2.** Let \( X \in \text{LC} \). Let \( \mathcal{V} \) be an open cover of \( X \). Let \((U, I)\) be a subset element of \( X \). If \( (V \cap U, V \cap I) \) is negligible for each \( V \in \mathcal{V} \), then \((U, I)\) is negligible.

**Corollary 3.** Let \( X, Y \in \text{LC} \), and let \( f : X \to Y \) be a function. Let \( \mathcal{V} \) be an open cover of \( X \). If, for each \( V \in \mathcal{V} \), the restriction of \( f \) to \( V \) is a diffuse function \( V \to Y \), then \( f \) is a diffuse function.

**Proof.** Trivial. \( \square \)
We are ready to define the categories to which we will apply the machinery of this paper’s predecessors. Trivially, Top-isomorphisms are diffuse and composition of diffuse continuous functions are diffuse.

**Definition 5.** Let Gen denote the subcategory of Top whose object class is LC and whose morphism class consists of all diffuse continuous functions between such objects. Define the subcategory HGen (respectively, HGen+) of Gen to have the class of all Hausdorff (respectively, locally Hausdorff) locally connected spaces for objects, and the class of all Gen-morphisms between such objects for morphisms.

The category Top has more than mere objects and morphisms. Each object supports a canonical Grothendieck topology. It is not hard to lift this topology—perhaps system of topologies is a better phrase—to Gen, HGen and HGen+.

2. **Pseudogeometric Topologies**

For this section,

(4) let $\mathcal{C}$ be Gen, HGen or HGen+.

We shall define on $\mathcal{C}$ a “canonical” topology, which we shall call the pseudogeometric topology. This topology has many special properties, as abstracted in [3], [4] and [5]. The formulations in these papers are non-standard. As the reader may not be familiar with the language, we go through verification carefully. Each individual step is rather simple. Difficult points have been addressed in earlier papers, in general form. Hopefully, work with the explicit categories of this paper will illustrate the ethereal machinery of its predecessors.

Definition of a categorical topology, in the sense of [3], begins with a selection of a class of special morphisms. Let $\text{Sub}$ denote the class of open embeddings (that is, open injections in Top) whose domain and codomain are in $\mathcal{C}$. Note that if $u : U \to X$ is an open embedding and $X \in \mathcal{C}$, then $U \in \mathcal{C}$ and $u$ is a $\mathcal{C}$-morphism. We claim that, in the language of [3] (2.1), $\text{Sub}$ is a universe of formal subsets. This amounts to three conditions:

(5.a) $\text{Sub}$ contains all $\mathcal{C}$-isomorphisms,
(5.b) composition of members of $\text{Sub}$ are in $\text{Sub}$,
(5.c) each member of $\text{Sub}$ is a pullback base, and every pullback of a member belongs to $\text{Sub}$.

The first two conditions are self-evident. The third involves a subtle point.

Let $f : X \to Y$ be a $\mathcal{C}$-morphism and let $u : U \to Y$ be an open embedding. Choose $V$ to be the inverse image, under $f$, of the image
of $u$. Let $v : V \rightarrow X$ be subset injection, and let $g : V \rightarrow U$ be the unique function such that $u \circ g = f \circ v$. Assign to $V$ the subset topology. Then $(V; v, g)$ is a pullback of $u$ along $f$ with respect to the category $\text{Top}$! More importantly, $U, V \in \mathcal{C}$ and each of $u, v$ and $g$ is diffuse. This suggests that the triple might also be a pullback with respect to $\mathcal{C}$. Indeed, $(V; v, g)$ is a pullback $f^{-1}u$ in $\mathcal{C}$. Proof relies on the following

**Lemma 6.** Assume (4). Let $f : X \rightarrow V$ be a continuous function between members of $\text{LC}$. Let $v : V \rightarrow Y$ be an open embedding into another member of $\text{LC}$. Then $v \circ f$ is diffuse if and only if $f$ is diffuse.

**Proof.** Trivial. □

Categorical pullbacks along open embeddings now have an explicit characterization. Condition (5.c) follows immediately.

It is unusual for a pullback of a $\mathcal{C}$-morphism, as defined in $\text{Top}$, to serve as a pullback in $\mathcal{C}$. We shall see later that $\mathcal{C}$ is not closed under arbitrary fibered product. We shall struggle with morphisms which are pullback bases but whose pullbacks in $\mathcal{C}$ disagree with their pullbacks in $\text{Top}$.

Having chosen a suitable $\text{Sub}$, we need a notion of cover. We say that a non-empty cone $S$ of open embeddings into an object $X \in \mathcal{C}$ covers if $X = \bigcup_{s \in S} \text{Im}(s)$. Formally, we choose $\text{Cov}$ to be the class of all non-empty cones of open embeddings with this property, and must verify that $\text{Cov}$ satisfies the conditions of [3, (2.9)]. Most are obviously true.

(6.a) Each $S \in \text{Cov}$ is a non-empty cone.
(6.b) If $S \in \text{Cov}$ and $T$ is a cone of open embeddings which contains $S$, then $T \in \text{Cov}$.
(6.c) If $b$ is a $\mathcal{C}$-isomorphism, then $\{b\} \in \text{Cov}$.
(6.d) If $S \in \text{Cov}$, and if $\theta(s) \in \text{Cov}$ is a cover of dom $s$ for each $s \in S$, then

$$\{s \circ u : s \in S, u \in \theta(s)\} \in \text{Cov}.$$  

(6.e) If $S \in \text{Cov}$ is a cover of $Y \in \mathcal{C}$ and if $f : X \rightarrow Y$ is a $\mathcal{C}$-morphism, then, for any choice of pullbacks, the set $\{f^{-1}s : s \in S\}$ belongs to $\text{Cov}$.
(6.f) If $f \in \text{Sub}$ and $\pi_1$ and $\pi_2$ are the canonical projections $f \times_{\text{cod}} f$ $f \rightarrow \text{dom} f$, then $\{\pi_1\}, \{\pi_2\} \in \text{Cov}$.  

Condition (6.e) relies on the explicit description of pullbacks. Condition (6.f) is less subtle; since each $f \in \text{Sub}$ is monomorphic, the two projections are isomorphisms!

We refer to $(\text{Sub, Cov})$ as the (canonical) pseudogeometric topology. Let us consider terminology and properties.

In earlier works, the author refers to members of $\text{Sub}$ as formal subsets. A formal subset $b$ for which $\{b\} \in \text{Cov}$ is called a covering morphism. In the present, explicit, context, we continue to refer to these key morphisms as open embeddings. In this topology, a morphism is a covering morphism if and only if it is a $C$-isomorphism.

The topology meets the smallness condition [3, (2.11)]. This is the categorical name for the observation that, for each $X \in C$,

(7.a) every open embedding into $X$ is $C/X$-isomorphic to a member of the set of subset injections of open subsets of $X$,
(7.b) given a family of open subsets of $X$, the issue of whether the family covers is set-theoretic.

Now suppose $\alpha$ and $\beta$ are two cones of open embeddings into an object $X \in C$. Suppose that for each $j \in \text{dom}(\alpha)$, there is an index $k \in \text{dom}(\beta)$ such that $\alpha(j)$ factors through $\beta(k)$. In addition, suppose that $\alpha$ covers $X$. Clearly, $\beta$ must cover $X$. This property of the topology is called the flushness condition [3, Definition 2.19].

Several categorical formulations rely on canopies. Let us first consider the canopy of a cover, as in [3, (2.21)]. Let $X \in C$, and let $\theta$ be a non-empty cone of open embeddings into $X$. Without loss of generality, we may assume that for each $j \in J = \text{dom}(\theta)$, $\theta(j) : U(j) \to X$ is subset injection. Consider a graph $A_0$, whose objects are indexed by $J \cup J^2$, in which

$$A_0[j] = U(j) \quad \text{for each } j \in J,$$
$$A_0[j, k] = U(j) \cap U(k) \quad \text{for } j, k \in J,$$

and in which the only morphisms are the injections $A_0[j, k] \to A_0[j]$ and $A_0[j, k] \to A_0[k]$ for all choices $j, k \in J$. Consider the cone $\alpha : A_0 \to X$ in which $\alpha(t)$ is subset injection for each index $t$. Then $A_0$ is a canopy of $\theta$, and $\alpha$ is its canonical cone into $X$.

We claim that if $\theta$ is a cover, then $\alpha$ is a colimit. Unwinding definitions, the colimit condition becomes:

(8) Suppose that $Y \in C$ and $\{f(j) : U(j) \to Y\}$ is a family of diffuse continuous functions such that, for any $j, k \in J$, $f(j)$ and $f(k)$ agree on $U(j) \cap U(k)$. Then there is a unique diffuse continuous function $f : X \to Y$ such that, for each $j \in J$, $f(j)$ is the restriction of $f$ to $U(j)$.
This is Corollary 3. Note that if \( \theta \) is a cover, the canonical cone of any canopy for any pullback of \( \theta \) (which is also a cover) is a colimit. In the language of [3, Theorem 2.28], the topology is intrinsic.

Two of our categories are global structures. For that reason, we add some comments on abstract canopies.

Let \( A_0 \) be an abstract canopy, in the sense of [3, Definition 3.4], with respect to the pseudogeometric topology on \( \mathcal{C} \). Put \( J = \Lambda(A_0) \). For each \( j \in J \), we have a \( \mathcal{C} \)-object \( A_0[j] \); for each pair \((j, k) \in J^2\), we have an object \( A_0[j, k] \) and canonical open embeddings \( \rho_1 : A_0[j, k] \to A_0[j] \) and \( \rho_2 : A_0[j, k] \to A_0[k] \). We are interested in the issue of whether \( A_0 \) has an affinization. That is, whether there is an object \( X \in \mathcal{C} \) and a family of open embeddings \( \alpha(j) : A_0[j] \to X \), one for each \( j \in J \), such that,

(9.a) \( \{\alpha(j)\}_{j \in J} \) is a cover of \( X \), and
(9.b) for \( j, k \in J \), \( (A_0[j, k]; \rho_1, \rho_2) \) is a fibered product \( \alpha(j) \times_X \alpha(k) \).

In fact, there is an easy construction for \( X \).

Let

\[
X_1 = \{(x, j) : j \in J, x \in A_0[j]\},
\]

and

\[
R = \{(x, j), (y, k) : \exists z \in A_0[j, k] \text{ for which } x = \rho_1(z) \text{ and } y = \rho_2(z)\}.
\]

For each \( j \in J \), let \( \beta(j) \) be the function \( x \mapsto (x, j) \) from \( A_0[j] \to X_1 \). With respect to a unique choice of topology on \( X_1 \), \( X_1 \) paired with the morphisms \( \beta(j) \) becomes a disjoint union of the family \( \{A_0[j]\}_{j \in J} \).

The first remark is that \( R \) is an equivalence relation on \( X_1 \). Reflexivity for \( R \) relies on axiom [3, (3.5.e)] that \( A_0 \) be a canopy. The latter requires that, for each \( j \in J \), there is a function \( \delta : A_0[j, j] \to A_0[j] \) such that, for each \( x \in A_0[j] \), \( \rho_1(\delta(x)) = x = \rho_2(\delta(x)) \). Similarly, the symmetry property is a consequence of another axiom [3, (3.5.d)] phrased in terms of existence of a morphism. The transitivity property comes from [3, (3.5.e)], although here we need to know about pullbacks as well. That conditions states that, for \( i, j, k \in J \), there is a function

\[
\omega : (A_0[i, j], \rho_2) \times_{A_0[j]} (A_0[j, k], \rho_1) \to A_0[i, k]
\]

with good properties. The relevance is as follows: suppose \((x, i), (y, j)\) and \((y, j), (z, k)\) belong to \( R \). Take \( r \in A_0[i, j] \) and \( s \in A_0[j, k] \) for which

\[
\rho_1(r) = x, \rho_2(r) = y = \rho_1(s) \text{ and } \rho_2(s) = z.
\]

Then \((r, s)\) represents a member of \( A_0[i, j] \times_{A_0[j]} A_0[j, k] \), and

\[
\rho_1(\omega(r, s)) = \rho_1(r) = x \text{ and } \rho_2(\omega(r, s)) = \rho_2(s) = z \Rightarrow ((x, i), (z, k)) \in R.
\]
Three of our categorical formulations are no more than the axioms of an equivalence relation!

We can now define a quotient space (with canonical projection) \( q : X_1 \to X (= X_1/R) \) and define \( \alpha(j) = q \circ \beta(j) \) for each \( j \in J \). It remains to check (9.a,b).

Once we show that each \( \alpha(j) \) is an open injection, then (9.a) is a tautology. First, fix \( j \in J \). Each projection \( A_0[j, j] \to A_0[j] \) is injective, and composes with the diagonal \( \delta \) to get the identity function. Consequently, each projection, and \( \delta \), is an isomorphism. It follows that distinct members of \( A_0[j] \) are not equivalent mod(\( R \)). In other words, \( \alpha(j) \) is injective. Next, the assumption that every projection \( A_0[j, k] \to A_0[j] \) and \( A_0[j, k] \to A_0[k] \) is open directly implies that, for \( U \subseteq X_1 \) an open subset, the set of all \( x \in X_1 \) which are equivalent to a member of \( U \) is also open. Consequently, \( \alpha(j) \) is an open embedding for every \( j \in J \).

We know explicitly how to take a fibered product of open embeddings in \( C \). In particular, any construction of a fibered product in \( \text{Top} \) suffices. Thus, we may characterize \( \alpha(j) \times_X \alpha(k) \) as the set \( \{ (r, s) : \alpha(j)(r) = \alpha(k)(s) \} \) paired with a specific topology. That the latter must be isomorphic to \( A_0[j, k] \) is trivial. Condition (9.b) follows.

There is one problem: does \( X \) belong to our category? If so, then we may conclude that our construction is an affinization. If \( C \) is \( \text{Gen} \) or \( \text{HGen}^+ \), it is clear that \( X \) always will be an object. At this point, we may deduce

(10) The categories \( \text{Gen} \) and \( \text{HGen}^+ \) are closed under affinization.

On the other hand, it is clear that there are choices for the canopy \( A_0 \) in \( \text{HGen} \) for which \( X \) is not Hausdorff.

Next, we claim that \( C \) meets the \( \text{CLCS} \) criterion. This criterion has several parts. Let \( Cvm \) be the class of covering morphisms—in our cases, the class of all \( C \)-isomorphisms. We require that \( Cvm \) be a universe of layered morphisms. This means, firstly, that the analogues to (3,a,b,c) are true with \( Cvm \) in place of \( \text{Sub} \); obviously, this much is true. In addition, we require that if \( b : B \to A \) is a \( C \)-morphism and if \( S \) is a cover of \( A \) such that \( s^{-1}b \in Cvm \) for each \( s \in S \), then \( b \in Cvm \). This implication is a trivial consequence of the fact that the topology is intrinsic (which implies that \( B \) and \( A \) are colimits of the same canopy).

Suppose \( b : B \to A \) is a \( C \)-morphism and \( S \) is a cover of \( B \) such that, for each \( s \in S \),

(11.a) \( b \circ s \) is an open embedding,
(11.b) \( b^{-1}(b \circ s) \) exists, and is an isomorphism.

The last part of the CLCS criterion demands that, under (11.a,b), \( b \) must be an open embedding. The implication requires a short paragraph.

Let \( b \) satisfy (11.a,b). We claim that \( b \) is an open embedding. Given (11.a), it suffices to show that \( b \) is injective. Without loss of generality, assume that \( S \) consists of injections of members of a family of open subsets \( \mathcal{U} \). Now suppose \( x, y \in B \) such that \( b(x) = b(y) \). Take \( U \in \mathcal{U} \) such that \( x \in U \). Condition (11.b) translates as \( U = b^{-1}(b(U)) \) for each \( U \in \mathcal{U} \). Thus, \( y \in U \). But, by assumption, the restriction of \( b \) to \( U \) is an open embedding, which means \( x = y \).

The last axiom discussed in [3, Definition 14.1] is that \( C \) be complete (or closed) under \( Cvm \). The issue is as follows. Suppose \( J \) is a set and \( A_0 \) and \( Q_0 \) are two canopies of type \( \text{Int}(J) \) (that is, objects indexed by \( J \cup J^2 \), morphisms between appropriate members) and let \( q \mapsto q[\alpha] \) be a graph transformation \( Q_0 \rightarrow A_0 \). Assume that for \( j, k \in J \), the triples \( (Q_0[j,k]; \rho_1, q[j,k]) \) and \( (Q_0[j,k]; \rho_2, q[j,k]) \) are fibered products \( (Q_0[j], q[j]) \times_{A_0[j]} (A_0[j,k], \rho_1) \) and \( (Q_0[k], q[k]) \times_{A_0[k]} (A_0[j,k], \rho_2) \), respectively. We call \( (Q_0, q) \) a pullback system into \( A_0 \). If \( \text{Aux} \) is a universe of layered morphisms and \( q[\alpha] \in \text{Aux} \) for each \( \alpha \in J \cup J^2 \), we call it a pullback system of \( \text{Aux} \)-morphisms. Our last condition is that if \( (Q_0, q) \) is a pullback system of \( Cvm \)-morphisms for \( A_0 \) and if \( A_0 \) has an affinization, then \( Q_0 \) has an affinization. Since \( Cvm \) consists of isomorphisms, the implication is vacuous. We shall look at closure for more interesting notions of layered morphisms shortly.

We can summarize our work so far.

**Theorem 7.** With respect to their respective pseudogeometric topologies, the categories \( \text{Gen} \) and \( \text{HGen}^+ \) are global structures, and \( \text{HGen} \) is a local structure, in the sense of [3, Definition 14.1].

**Corollary 4.** The subcategory injection functor \( \text{HGen} \rightarrow \text{HGen}^+ \) is, with respect to the pseudogeometric topologies, a globalization.

**Proof.** The key points in the proof of the Corollary are summarized in [3, Remark 14.6]. □

Our three categories are linked intimately to the topological notion of connectedness. The next step is to show that the topological version implies the categorical notion of connectedness developed in [4, (16.a,b)] and [3, Definition 13]. We prove that each of our categories is topologically componentwise.

Let \( \emptyset \) denote the empty space. Then
(12.a) For each $B \in C$, there is a unique $C$-morphism $\emptyset \to B$.
(12.b) If $b : B \to \emptyset$ is a $C$-morphism, then it is an isomorphism.

That is, $\emptyset$ is an empty object in the sense of $[4, (14.a,b)]$.

Let $B, C \in C$, and let $A$, paired with canonical injections $b : B \to A$ and $c : C \to A$, be a disjoint union, in the topological sense. Trivially, $A \in C$ is a disjoint union in the categorical sense. That is, if $Y \in C$ and $f : B \to Y$ and $g : C \to Y$ are diffuse continuous function, then there is a unique diffuse continuous function $h : A \to Y$ such that $f = h \circ b$ and $g = h \circ c$. The two morphisms $b$ and $c$ are open embeddings, and the pair $\{b, c\}$ covers $A$. The fibered product $b \times_A c$ is empty. If $f : D \to A$ is a $C$-morphism, then pulling back $b$ and $c$ along $f$ determines a disjoint union structure on $D$.

The last paragraph has several tautological implications.

(13.a) $C$ is componentwise,
(13.b) a $C$-object is connected in the categorical sense if and only if it is connected in the topological sense,
(13.c) a $C$-morphism is complemented in the categorical sense if and only if it is complemented in the topological sense,
(13.d) the pseudogeometric topology meets the first and last conditions in $[4, (18)]$.

Let $\text{Comp}$ denote the class of complemented morphisms.

We must show that $\text{Comp}$ is a universe of layered morphisms under which $C$ is closed. Conditions (5.a,b,c) are trivial. Now suppose $b : B \to A$ is a $C$-morphism and $U$ is an open cover of $A$ such that, for each $U \in U$, the restriction of $b$ to $b^{-1}U$ is complemented. We leave it for the reader to check that $b$ must be complemented.

Finally, we claim that the category is closed with respect to complemented morphisms. In $\text{Gen}$ and $\text{HGen}^+$, every canopy has an affinization, so the claim is tautological. Now assume $C = \text{HGen}$. Suppose $(Q_0, q)$ is a pullback system of complemented morphisms to a canopy $A_0$, and $a^\sharp : A_0 \to A$ is an affinization in $\text{HGen}$. Let $q^\sharp : Q_0 \to Q$ be an affinization in $\text{Gen}$, and let $f : Q \to A$ be the unique morphism such that $f \circ q^\sharp[\alpha] = a^\sharp[\alpha] \circ q[\alpha]$ for each $\alpha \in J \cup J^2$. General nonsense implies that $f$ is a complemented morphism with respect to $\text{Gen}$. It follows that the domain of $f$ is in $\text{HGen}$, which means that $q^\sharp$ is an affinization in $\text{HGen}$.

**Theorem 8.** The pseudogeometric topologies of $\text{Gen}$, $\text{HGen}$ and $\text{HGen}^+$ are topologically componentwise. Moreover, in each category, every object has a cover by connected objects.
3. The Pseudoétaile Topology

Let $\mathcal{D}$ be a topologized category which is flush, intrinsic, closed under descent and such that every formal $\mathcal{D}$-subset is monomorphic. Then the definition of superopen from [3, Section 5] makes sense in $\mathcal{D}$. Moreover, if $\mathcal{D}$ is topologically componentwise, and every $\mathcal{D}$-object has a cover by connected objects, then we can define the derived pseudoétaile and torsorial topologies on $\mathcal{D}$ as well. Thus, without further comment, it follows that Gen and HGen$^+$ support topologies suitable for orbifolds.

Or rather, they almost do. Earlier papers developed the machinery necessary to generate topologies which, in turn, generate categories of formal quotients (and of formal quotients “pasted” together. We will not add to that theory. Instead, we raise several significant points about that construction. In these notes, we focus on the pseudoétaile topology.

3.1. Terminology. We have provided categorical definitions for topological words like “discrete”, “open”, “finite”, etc. In Gen, these phrases need not assume their standard meanings. Indeed, Gen is created specifically as a context where a discrete morphism can have, in the traditional sense, a small set of ramification.

Discussion of terminology is hampered by the lack of a construction for a pullback of one Gen-morphism along another. However, we will make some elementary points. When we are using a term in the general, categorical sense, we shall prefix it with “c-”; otherwise, words have the usual meaning in point-set topology. In what follows

(14) Let $\mathcal{C}$ be either Gen or HGen$^+$.

**Proposition 9.** Assume (14). Let $b : B \to A$ be a C-morphism which overlays absolutely. Then $b$ is surjective, in the usual sense.

**Proof.** Unfortunately, we do not have one argument that works in general. Instead, we offer a line of reasoning for each choice of $\mathcal{C}$.

First, suppose $\mathcal{C}=\text{HGen}^+$. Every pullback of $b$ along a formal subset also overlays absolutely. These pullbacks agree with the usual sense of pullback. Hence, without loss of generality, we may assume that $A$ is Hausdorff. We proceed by contradiction.

Assume $x \in A$ is not in the image of $b$. The subset $U = A - \{x\}$ belongs to $\mathcal{C}$, and injection $\iota : U \to A$ is a C-morphism. Moreover, there is a C-morphism $c : B \to U$ such that $b = \iota \circ c$. Let $(P;p,q)$ be a self-product $b \times_A b$. Clearly $c \circ p = c \circ q$. Since $b$ is a colimit of the canopy of $\{b\}$, the latter implies that $1_A$ factors through $\iota$, which is absurd.
Next, suppose that $C = \text{Gen}$. Let $C$ denote the set $\{0, 1\}$ with the indiscrete topology—that is, the only open subsets of $C$ are $\emptyset$ and $\{0, 1\}$. Trivially, the point-set topological product $A \times C$ belongs to $C$.

Define two functions $f, g : A \to A \times C$ by $f(x) = (x, 0)$ and
\[
g(x) = \begin{cases} (x, 0) & \text{if } x \text{ is in the image of } b, \\ (x, 1) & \text{otherwise.} \end{cases}
\]

It is routinely verified that $f$ and $g$ are $C$-morphisms. By inspection, $f \circ b = g \circ b$. However, $b$ is known to be epimorphic, and so $f = g$. This implies that $b$ is surjective. $\blacksquare$

**Corollary 5.** Assume (14). Suppose that $f : B \to W$ is a $C$-morphism which overlays absolutely, and that $w : W \to A$ is an open embedding. Then the image of $w$ is the same as the image of $w \circ f$.

**Corollary 6.** Assume (14). Then a $c$-open $C$-morphism is open in the usual sense.

**Corollary 7.** Assume (14). A cone of pseudoétale morphisms covers if and only if the union of the images of the members of the cone equals the common codomain.

**Proof.** In this order, the Corollaries have obvious proof. $\blacksquare$

**Corollary 8.** Assume (14). Let $b : B \to A$ be a $c$-open $C$-morphism, and let $c : C \to A$ be an arbitrary $C$-morphism with the same codomain. Suppose $x \in C$ such that $c(x)$ is in the image of $b$. Then $x$ lies in the image of any choice of $c^{-1}b$.

**Proof.** Let $U$ be the image set of $b$, and let $V = c^{-1}U$. Let $u : U \to A$ and $v : V \to C$ be subset injection. Now $b$ is composition of $u$ with a morphism that overlays absolutely. Hence, the pullback of $b$ along $u$ overlays absolutely. Since $v$ is a pullback of $u$, it follows that the pullback of $c^{-1}b$ along $v$, which is a pullback of $u^{-1}b$, overlays absolutely. Consequently, the latter is surjective. The proposition follows now from the fact that pullback along open embeddings agrees with the usual sense of pullback. $\blacksquare$

**Lemma 10.** Assume (14). Let $b : B \to A$ be a $c$-discrete $C$-morphism. If $x, y \in B$ such that $x \neq y$ and $b(x) = b(y)$, then there is a neighborhood $U$ of $x$ which does not contain $y$. 
Proof. If $B \in \text{HGen}^+$, the conclusion is true for any two distinct points in $B$. Assume $C = \text{Gen}$, and suppose that $y$ is contained in every neighborhood of $x$. Note that if $X$ is a subset of $B$ which contains $x$ and $y$, and if $I$ is a closed subset of $X$ which contains $y$, then $x \in I$.

Consider the function $f : B \rightarrow B$ which is the identity on $B - \{x\}$ but which maps $f(x) = y$. It follows that if $U \subseteq B$ is an open subset, then $U \subseteq f^{-1}U$. Thus, $f$ is continuous. If $T$ is a subset of $B$, the $f^{-1}T = T - \{x\}$ or $T$.

A criterion for connectedness is needed. We claim that

(15) Let $C$ be an open subset of $B$. Then $C$ is connected if and only if $C - \{x\}$ is connected.

Let $C$ be an open subset which contains $x$. Then $y \in C$, which implies that $C$ lies in the closure of $C - \{x\}$. Implication (15) follows.

We observe next that $f$ is diffuse. Suppose $(U, I)$ is a negligible subset-element of $B$. If $x \in U$, it follows that $f^{-1}(U, I) = (U, I)$ is negligible. If $y \notin U$, then $f^{-1}(U, I) = (U, I)$ is negligible. There remains the case where $x \notin U$ and $y \in U$. Put $U^* = U \cup \{x\}$ and $I^* = I \cup \{x\}$. Then $f^{-1}(U, I)$ is $(U^*, I^*)$ or $(U^*, I)$. Remark (15) proves negligibility in either case.

Let $Y$ be the connected component of $x$ in $B$. Then $f_1$, the restriction of $f$ to $Y$, and $g_1 = 1_Y$, interpreted as diffuse maps into $B$, satisfy

$$b \circ f_1 = b \circ g_1 \text{ and } f_1 \neq g_1.$$ 

Consider $D = Y - \{x\}$, and let $d : D \rightarrow Y$ be subset injection. From (15), it is easy to show that

(16.a) $D \in \text{Gen}$,

(16.b) $d$ is diffuse.

Then $D \neq \emptyset$ and $f_1 \circ d = g_1 \circ d$. But this contradicts the discreteness of $b$. $\square$

**Proposition 11.** Assume (14). Let $b : B \rightarrow A$ be an $c$-open, $c$-discrete $C$-morphism which is finite of order $n \in \mathbb{N}$. Then, for each $x \in A$, $b^{-1}\{x\}$ has at most $n$ elements. Moreover, for each $x \in A$ for which $b^{-1}\{x\} \neq \emptyset$, there is a connected, $c$-finite, $c$-open, $c$-discrete $C$-morphism $c : C \rightarrow A$ with a point $z \in C$ such that

(17.a) $c(z) = x$, and

(17.b) for each $y \in b^{-1}\{x\}$, there is at least one morphism $f : C \rightarrow B$ for which $b \circ f = c$ and $f(z) = y$.

Proof. Fix $x \in A$ such that $b^{-1}\{x\} \neq \emptyset$. Suppose $C$ is a non-empty connected $C$-object, $c \in \text{Mor}_C(C, A)$, $z \in C$ and $f_1, \ldots, f_k$ is a finite list
\(C/A\)-morphisms \((C, c) \rightarrow (B, b)\) such that \(c(z) = x\) and \(f_i \neq f_j\) for all pairs of distinct indices \(i\) and \(j\). Suppose \(y \in b^{-1}\{x\}\) such that \(f_j(z) \neq x\) for every \(j \in IN(k)\).

By the previous lemma, there is an open neighborhood \(U\) of \(y\) which does not contain \(f_j(z)\) for any \(j \in IN(k)\). Let \((D; d, p)\) be a pullback of the restriction of \(b\) to \(U\) along \(c\). By Corollary 8, there is a point \(z^* \in d^{-1}\{z\}\). Let \(e : E \rightarrow D\) be the identity map on the connected component of \(z^*\) in \(D\). Since \(b\) is discrete, \(f_i \circ d \circ e \neq f_j \circ d \circ e\) for any two distinct indices \(i\) and \(j\).

Let \(u : U \rightarrow B\) be subset injection. For each index \(j\),
\[
b \circ f_j \circ d \circ e = c \circ d \circ e = b \circ u \circ p \circ e,
\]
Put \(q = u \circ p \circ e\). By choice, \(q(z) \neq \{f_j \circ d \circ e\}(z^*)\). (We do not claim that \(q(z)\) actually equals \(y\), however.) Replacing \(c : C \rightarrow A\) and \(z\) by \(c \circ d \circ e : E \rightarrow A\) and \(z^*\), we can now recreate the hypothesis of this construction but with an indexed list, of morphisms, of length \(k + 1\).

The properties of \(c\)-openness, \(c\)-finiteness and \(c\)-discreteness are preserved by pullback and composition with complemented morphisms. Proof of our proposition is now a trivial consequence of the above construction. □

**Corollary 9.** Assume \((\mathbb{I}4)\). Let \(b : B \rightarrow A\) be a \(c\)-finite, \(c\)-discrete, \(c\)-open \(C\)-morphism. Let \(c : C \rightarrow A\) be a \(C\)-morphism with the same codomain, and let \((P; p, q)\) be a fibered product \(c \times_A b\). Suppose \(x \in B\) and \(y \in C\) such that \(b(x) = c(y)\). Then there is \(z \in P\) such that \(p(z) = y\) and \(q(z) = x\).

**Proof.** Let \(x\) and \(y\) be as hypothesized. Let \(w = b(x) = c(y)\). By Proposition \(\mathbb{I}4\) and Lemma \(\mathbb{I}4\), there is an open neighborhood \(U\) of \(x\) which contains no other members of \(b^{-1}\{w\}\). In a canonical sense, \(q^{-1}U\) is a pullback of the restriction of \(b\) to \(U\) along \(c\). Thus, there is \(z \in q^{-1}U\) such that \(p(z) = y\). The only possible value of \(q(z)\) is \(x\). □

**Remark 1.** A particular self-product may illustrate the previous Corollary. Let \(n \in IN\), let \(G\) be the multiplicative group of complex \(n\)-th roots of unity, and let \(b\) be the function \(b(z) = z^n\) from \(C \rightarrow C\). Let \(X\) be the disjoint union of \(n\) copies of \(C\), indexed by \(G\). Define \(\pi_1\) and \(\pi_2\) on \(X\) by, for each \(\omega \in G\), letting \(\pi_1\) be the identity map and \(\pi_2\) be multiplication by \(\omega\) on the \(\omega\)-th copy of \(C\) in \(X\). In \(\text{Top}\), the self-product \(b \times b\) derives from \((X; \pi_1, \pi_2)\) if we identify the 0’s of the copies of \(C\) as one point. In \(\text{Top}\), for each pair \((r, s)\) of complex numbers for which
$r^n = s^n$, there is a unique member $w$ of the product such that $r = \pi_1(w)$ and $s = \pi_2(w)$. However, although the underlying object of the product in $\textbf{Top}$ belongs to $\textbf{HGen}$, the two projections are not diffuse; the origin in $\mathcal{C}$, a negligible set, pulls back to a non-negligible set. With respect to $\textbf{HGen}$, $(X; \pi_1, \pi_2)$ is the self-product. To get a product in the context of diffuse functions, we must allow for points which cannot be distinguished by $\pi_1$ and $\pi_2$.

In our example, we can say that for a pair $(r, s)$ for which $r^n = s^n$, there is at least one point in the product whose first and second projection are $r$ and $s$, respectively. Corollary 9 assures us that, at least for products with a c-finite, c-discrete, c-open morphism, any pair of points $(x, y)$ which are sent to the same image do arise as first and second projections of something in the product.

3.2. The Pseudo´etale Topology is not closed under Descent.

Corollary 9 is more important than it may appear at first. Suppose $A_0$ is a canopy in $\mathcal{C}$ (with respect to the pseudo´etale topology). Put $J = \Lambda(x)$. Let $X$ be the (topological) disjoint union of the sets $\{A_0[j]\}_{j \in J}$; for each index $j$, let $\beta[j]$ be the canonical injection $A_0[j] \rightarrow X$. Define a relation $R$ (signified by $\sim$) on $X$ by, for all appropriate choices of parameters, $\beta[j](x) \sim \beta[k](y)$ if and only if there is $z \in A_0[j, k]$ such that $\rho_1(z) = x$ and $\rho_2(z) = y$. Reflexivity and symmetry of $R$ follow trivially. However, transitivity requires Corollary 9. That is, given indices $i, j, k \in J$, $s \in A_0[i, j]$ and $t \in A_0[j, k]$ for which $\rho_2(s) = \rho_1(t)$, we need the existence of $w \in (A_0[i, j], \rho_2) \times_{A_0[j]} (A_0[j, k], \rho_1)$ such that $s$ is the first projection of $w$, and $t$ is the second.

Since $R$ is an equivalence relation, we can define a quotient function $q : X \rightarrow Q$ for it in $\textbf{Top}$. By Corollary 9, all morphisms of the canopy are open in the traditional sense. It follows that $q$ is an open function. Consequently, $Q \in \textbf{Gen}$.

We claim that if $A_0$ has an affinization, then the specific cone $j \mapsto q \circ \beta[j]$ is also an affinization. To see this, assume that $\alpha : A_0 \rightarrow A$ is an affinization. There is a unique continuous function $f : X \rightarrow A$ such that

$$\alpha[j] = f \circ \beta[j] \text{ for each } j \in J.$$ 

Recall that $\alpha[j]$ is known to be open. It follows that $f$ is an open function. Our conclusion amounts to two conditions:

(18.a) $f$ is surjective, and
(18.b) for $r, s \in X$, $f(r) = f(s)$ if and only if $r \sim s$. 
Condition (18.a) follows from Corollary 7 and the requirement that \( j \mapsto \alpha[j] \) be a cover.

Let \( j, k \in J \), \( x \in A_0[j] \) and \( y \in A_0[k] \). We must show that the condition
\[
\beta[j](x) \sim \beta[k](y)
\] (19)
is equivalent to
\[
f(\beta[j](x)) = f(\beta[k](y)) \iff \alpha[j](x) = \alpha[k](y).
\] (20)

Since \( \rho_1 \circ \alpha[j] = \rho_2 \circ \alpha[k] \) on \( A_0[j, k] \), statement (13) implies (20). Conversely, assume (20). Another aspect of our affinization is that \((A_0[j, k], \rho_1, \rho_2)\) must serve as \( \alpha[j] \times_A \alpha[k] \). In this context, Corollary 4 implies (19).

It would be nice if the previous paragraphs were preparation for proof that the pseudoetale topology of Gen is closed under descent. Alas, this is not the case. Problems with quotients are well-known; see, for example, [13] and [14]. What follows is our spin on some well-known observations.

Let \( V \) be a real vector space, let \( \sigma \) be a non-identity linear automorphism of \( V \) such that \( \sigma^2 = 1_V \), and let \( G \) be the 2-group \( \{1_V, \sigma\} \). Consider \( V \) modulo \( G \). Actually, we ask a more restrictive question. We want to know whether a quotient \( G \backslash V \) exists which is pseudoetale. That is, the quotient must also have properties of finiteness and discreteness.

Let \( V^G \) be the disjoint union of two copies of \( V \), let \( \pi_1 : V^G \to V \) be the identity map on each copy and let \( \pi_2 : V^G \to V \) be the identity on one component and \( \sigma \) on the other. Let \( \Gamma \) be the graph consisting of \( V^G \), \( V \) and \( \{\pi_1, \pi_2\} \). Existence of a good quotient is equivalent to two requirements:
\[(21.a) \ \Gamma \text{ is a canopy}, \]
\[(21.b) \ \Gamma \text{ has an affinization}. \]

Each point merits comment.

Let \( W \) be the fixed point set of \( \sigma \). It has been observed several times in previous papers (see [3] Section 8) that \( \Gamma \) is a canopy provided that the equalizer of \( \{1, \sigma\} \) is the empty object. The latter conditions means that there must not be a non-empty Gen-morphism \( d : D \to V \) such that the image of \( d \) lies in \( W \). This requires verification.

Let us suppose that a troublesome morphism \( d : D \to V \) exists, and try to reach a contradiction. We may assume that the domain \( D \) is connected. If \( W \) is of codimension 2 or more in \( V \), then \( W \) is negligible in \( V \). Consequently, \( D = d^{-1}W \) is negligible in \( D \), an absurdity. Next, suppose \( W \) has codimension 1 in \( V \). Then every affine hyperplane of
$W$ is negligible in $V$ but divides $W$ into two connected components. Now the inverse image of a hyperplane $H$ in $D$ must be negligible. It follows that $d$ maps into one of the two half-spaces of $W$ bounded by $H$. Consequently, the image of any three points in $D$ must lie on a(n affine) line. Hence, the entire image of $D$ lies on a line!

At this point, our argument hits a twist. Suppose that $V$ has dimension at least 2, so that a point in $V$ is a negligible set. Using points to divide the image of $D$, we deduce that the image of $D$ can not be bigger than a single point, which leads to a contradiction. However, if $V$ has dimension 1 and $W = \{0\}$, the subset inclusion $d : \{0\} \rightarrow V$ is the unwanted equalizer! Indeed, in a one-dimensional real manifold, there are no non-empty negligible subsets. Therefore, every continuous function into a one-dimensional real manifold is diffuse!

**Remark 2.** The argument shows that a non-empty Gen-morphism into a topological manifold of dimension $n > 1$ can not map into any proper submanifold.

Hereafter, assume $V$ has dimension $\geq 2$. Consider the topological quotient $q : V \rightarrow G\backslash V$. The initial remarks of this subsection tell us that if an affinization exists, then $q$ is one. In fact, the canopy is so simple that it suffices to show that $q$ is pseudoétale. Alas, verification that $q$ is pseudoétale is non-trivial. Later, we prove Theorem [13] which states that $q$ has the desired properties if $W$ has codimension $\geq 2$. However, in the other case, it is simple to see that $q$ can not be pseudoétale.

Suppose $W$ has codimension 1. By inspection, $q(W)$ is a negligible subset of $V/G$. Yet, $W = q^{-1}(W)$ is not negligible in $V$. Hence, $q$ is not even diffuse!

**Remark 3.** Assume that $W$ has codimension 1. We have proved that a good quotient $G\backslash V$ does not exist in Gen. However, sometimes the quotient can exist in some category.

When $V = IR$, we encounter an intractable problem. The morphism $d : \{0\} \rightarrow V$ has the property that $d = \sigma \circ d$. Enlarging the category can not change this equation, which rules out existence of a Galois morphism $q : V \rightarrow Q$ with Galois group $G$.

Now assume that $\dim V \geq 2$. Since $\Gamma$ is a canopy, a suitable $G\backslash V$ will exist in Gen$^+$, as discussed in the next section. The topological quotient is inadequate. The problem will be studied in detail in Section 7, but we give a synopsis here.

It is possible to find Gen-morphisms $f, g : D \rightarrow V$ and $x_0 \in D$ such that

\[(22.a) \quad g(x) \in \{f(x), \sigma(f(x))\} \text{ for each } x \in D,
\]
(22.b) in any neighborhood of $x_0$, there exist $y, z$ such that
\[ g(z) = f(z) \neq \sigma(f(z)) \quad \text{and} \quad g(y) = \sigma(f(y)) \neq f(y) \]

Let $q : V \to G \backslash V$ be a topological quotient. In the topological sense, $q \circ f = q \circ g$. If $q$ were an affinization, then there would be a product map $\delta : D \to V^G = q \times q$ such that $f = \pi_1 \circ \delta$ and $g = \pi_2 \circ \delta$. Let $E$ be the connected component of $x_0$. Then, for all $x \in E$, we would have one of the identities

\[ f(x) = g(x) \text{ or } f(x) = \sigma(g(x)) \]

true for all $x \in E$. Yet, this is not the case.

We have assumed too much structure, and reached a contradiction. The reason is that, for $q_*^!: V \to Q$ the actual quotient in an enlarged category, $q_*^! \circ f$ and $q_*^! \circ g$ are not the same.

3.3. Expansions. Suppose $C$ is a category of orbifolds of active interest. Attaching a topological space to each object amounts to introducing a continuous functor $\Gamma : C \to \text{Gen}$. Extending the topological model to an enlargement of $C$, via the plus functor, means lifting $\Gamma$ to a new continuous functor $\Gamma^+$ on $C^+$. Unfortunately, since $\text{Gen}$ is not closed under descent, there may not be an extension to $C^+ \to \text{Gen}$.

It is necessary to have $\Gamma^+$ defined on all members of $C^+$, which means we need a codomain. The “obvious” choice is $\text{Gen}^+$. Indeed, if $\text{Gen}^+$ exists, the extension theorem follows from work in this series. The problem is that we can not yet prove that the plus construction applies to $\text{Gen}$!

The problem is formal, not substantial. As observed in [3, Section 3], the only obstruction is to show that the class of global classes between two $\text{Gen}$-objects is representable by a set. In fact, we make the

Conjecture 12. The pseudoétalementopology for $\text{Gen}$ meets the smallness axiom for a categorical topology. The torsorial topology does not meet the smallness condition, but does satisfy [3, (11)].

After all, every pseudoétale morphisms into $X \in C$ is in the set of finite-to-one maps to $X$. Unfortunately, the conditions used to define the pseudoétale topology are not framed in set-theory.

It is not difficult to get around the immediate problem. Let $S$ be an infinite set, and let $\text{Gen}[S]$ be the subcategory of objects which admit a cover by open sets of cardinality less than or equal to the cardinality of $S$. Assign to $\text{Gen}[S]$ the obvious restriction of the topology. All of the arguments in $\text{Gen}$ in this paper apply equally well $\text{Gen}[S]$. The difference is that $\text{Gen}[S]$ is the globalization of a small
local structure—specifically, of the subcategory of \textbf{Gen} objects entirely of cardinality less than or equal to the cardinality of \( S \). In practical examples, \( S = IR \) generates a category containing the desired topological models.

Technically, the derived pseudoétale topology of \textbf{Gen} restricted to \textbf{Gen}[S] need not be the derived pseudoétale topology of \textbf{Gen}[S]. That is, at its face, it is possible that a \textbf{Gen}[S]-morphism \( f \) might be pseudoétale in \textbf{Gen}[S] but not in \textbf{Gen}. This seems unlikely. However, until we have better control over pullbacks, we can only

\textbf{Conjecture 13.} Let \( S \) be an infinite set, and let \( f \) be a \textbf{Gen}[S]-morphism.

\begin{enumerate}[(23.a)]
  \item \( f \) is torsorial in the category \textbf{Gen}[S] if and only if it is torsorial in \textbf{Gen}.
  \item \( f \) is pseudoétale in \textbf{Gen}[S] if and only if it is pseudoétale in \textbf{Gen}.
\end{enumerate}

Even without the conjecture, we have a context which allows for arbitrary repetition of the plus construction.

\textbf{3.4. Functors and Pseudoétale Topologies.} Let \( S \) be a set, let \( \mathcal{M} \) be a pseudogeometric topologized category and let \( \Gamma : \mathcal{M} \rightarrow \textbf{Gen}[S] \) be a continuous functor with respect to the pseudogeometric topology on \textbf{Gen}[S]. For example, \( \Gamma \) might be the forgetful functor on a category of manifolds \( \mathcal{M} \), which might be differentiable, Riemmanian, analytic, complex, etc. It is not necessarily true that \( \Gamma \) is continuous with respect to the derived pseudoétale topologies.

In practice, it seems reasonable. However, the author suspects that proof of continuity in a specific case depends on the particulars of \( \mathcal{M} \). An old example illustrates the problem. Let \( n \in IN, n > 1 \), and let \( g : \mathcal{C} \rightarrow \mathcal{C} \) be the function \( g(z) = z^n \). We shall prove in Section 5 that \( g \) is pseudoétale in the context of \textbf{Gen}. In the sense of real manifolds, \( g \) does not even overlay absolutely. Yet, in the category of complex analytic manifolds with diffuse morphisms, \( g \) appears again to be pseudoétale. What we expect to be true is that if \( h \) is pseudoétale in the sense of real manifolds, or any other kind of structure, it must pseudoétale in \textbf{Gen} and if \( h \) is pulled back along another morphism \( f \), then the underlying space of the pullback is the pullback \( f^{-1}h \) in \textbf{Gen}.

It may seem odd that the author introduce a notion whose compatibility with continuous functors is questionable. There is logic behind the formulation of pseudoétale morphisms. Our thesis has been that the parameters of formal objects are set at the categorical level. Even
the study of \( g \) in the above paragraph suggests that context rather than intrinsic nature determine whether singularities prevent good structure.

For all its formalism, the definition of being pseudo\'{e}tale is negative. It is motivated by a question: Given a morphism \( b \), how can one determine that, even in an enlarged category, \( b \) will not obey the rules of manipulation that we need? Rather than turn the question on concrete issues, such as the shape of singular sets, the author started with a list of categorical manipulations to be allowed and tried to define a pseudo\'{e}tale morphism as anything for which those manipulations did not lead to contradiction.

The advantage of such a definition is that a category like \( \text{Gen} \) comes with an intrinsically defined notion of pseudo\'{e}tale morphism, even before singular sets are studied. Of course, in order to show that a morphism with singularities actually meets the abstraction requires work. Only after Sections 4 and 5 will we have interesting examples.

It is not hard to modify the definition in the context of a model. Let \( \Gamma : \mathcal{M} \rightarrow \text{Gen}[S] \) be as above. As usual, interpret it as assigning an underlying base space to each \( \mathcal{M} \)-object. If we want to enlarge \( \mathcal{M} \) in a manner that assures that \( \Gamma \) lifts, a modified topology can be used. Define a \( \mathcal{M} \) morphism \( b \) to be \( \Gamma \)-pseudo\'{e}tale if and only if

\[
\begin{align*}
(24.a) & \quad b \text{ is pseudo\'{e}tale in } \mathcal{M}, \\
(24.b) & \quad \Gamma(b) \text{ is pseudo\'{e}tale in } \text{Gen}[S], \text{ and} \\
(24.c) & \quad \Gamma \text{ preserves all pullbacks along } b.
\end{align*}
\]

The \( \Gamma \) will be continuous with respect to the corresponding topology on \( \mathcal{M} \) and the pseudo\'{e}tale topology of \( \text{Gen}[S] \).

The author’s guess is that, in examples of interest, continuity will be true but very hard to prove. A situation in which a morphism can be pseudo\'{e}tale but not \( \Gamma \)-pseudo\'{e}tale would be exceptionally interesting.

One key reason for pseudo\'{e}tale topologies is the need for a topology of finite-to-one morphisms to enable the plus construction to produce quotients. There is a very easy way to define such topologies. Let \( \mathcal{C} \) be a pseudogeometric topology (one in which formal subsets are monomorphic). A \( \mathcal{C} \)-morphism \( b \) is called a local subset if there is a cover \( S \) of \( \text{dom} b \) such that \( b \circ s \) is a formal subset for every \( s \in S \). Let \( FDL \) be the class of all local subsets which are finite and discrete. With an obvious notion of cover, \( FDL \) becomes a topology which meets the axioms of a pseudo\'{e}tale topology. We call it the elementary finite-to-one topology. It is not as rich as the derived pseudo\'{e}tale topology.

For example, in the study of \( G \) and \( V \) from Subsection 3.2, we would conclude that \( G \setminus V \) never exists in \( \text{Gen} \), but does exist in \( \text{Gen}^+ \) whenever \( \dim V \geq 2 \). Because of the simplicity of the topology, the plus
functor introduces so many new objects that even when $W$ has codimension $\geq 2$, the topological quotient $q : V \to G\backslash V$ loses the quotient property in the enlarged category.

In the real case, it is the elementary finite-to-one topology that is in common usage. For that reason, we suspect the following to be true

**Conjecture 14.** Let $\mathcal{M}$ be the subcategory of $C^n$-manifolds (where $n \in \mathbb{N}$ or $n = \infty$) consisting of all manifolds but only diffuse $C^n$-functions. Then the pseudoétale and elementary finite-to-one topologies agree.

### 3.5. Missing Things

There are two kinds of objects that our theory does not allow for. One is not of great technical concern, the other is more serious.

In limiting our categories' version of morphism, we have effectively abolished any notion of sub-object. Closed subsets can not be translated into morphisms in our context. Products are rare, which means that an abstract form of the Rank Theorem can not be formulated.

More serious is the lack of group objects. Aside from (categorical analogues to) finite groups), there are virtually no abelian group object. This impacts on our ability to define cohomology for our very formal objects.

Each object supports a topology in the sense of Grothendieck. Consequently, cohomological theories arise naturally from any “sheaf” into the category of abelian groups. In our language, **functors of sections** are used in place of sheaves, and our theory includes existence and uniqueness of liftings for such functors.

In many theories, for $A$ an abelian group object, the functor $\text{Mor}(\ast, A)$ is a functor of sections and begats cohomology. Sometimes, one can adapt traditional group objects to the task. Suppose $A$ is an abelian topological group. Although $A$ may not exist in $\text{Gen}$, we can define the functor $\Phi = \text{Mor}_{\text{Top}}(\ast, A)$. Because $A$ is outside $\text{Gen}$, it does not follow immediately that $\Phi$ is a functor of sections. If, however, it is, then it will lift to all expansions of $\text{Gen}$ via the plus construction. Verification that $\Phi$ is a functor of sections can be simplified by using \[6, Proposition 10\]

### 3.6. What is the Hausdorff Condition?

We have tracked Hausdorff objects because of precedent. Historically, objects of interest have some sort of separation property. Although the Zariski topology of a scheme is not Hausdorff, there is a weaker notion of “separated”. Unfortunately, the author is unaware of a separation property that can be characterized at the universal level.

It is well-known that a descent of separated (or Hausdorff) things can produce an unseparated object. However, it seems that global objects
are of less interest unless they are separated (and, typically, every local object is separated.)

The author has ideas on this topic. Indeed, we have a notion of separation, framed in the context of a topologically componentwise category, with respect to which the following is true:

(25) Let \( b : B \to A \) be a morphism and let \( S \) be a cover of \( B \) such that \( b \circ s \) is discrete for each \( s \in S \). If \( B \) is “separated”, then \( b \) is discrete.

However, before a definition can be made profitably, a more precise understanding of what separation should entail is needed.

We have no further results specific to \( HGen \) or \( HGen^+ \).

4. Representability of a Functor

Let \( X \in \text{Top} \) and let \( \mathcal{E} \) be a family of closed subset elements of \( X \). Define a contravariant functor \( F \), denoted by \( \text{Neg}(X, \mathcal{E}) \), from \( \text{Gen} \) to the category of sets as follows. For \( B \in \text{Gen} \), let \( F(B) \) be the set of continuous functions \( f : B \to X \) such that \( f^{-1}E \) is negligible for every \( E \in \mathcal{E} \). For \( b : B \to C \) a \( \text{Gen} \)-morphism, define \( F(b) : F(C) \to F(B) \) by \( f \mapsto f \circ b \).

Various issues reduce to representability of a functor this kind. For example, let \( A \in \text{Gen} \) and let \( \{b_j : B_j \to A\}_{j \in J} \) be a list of members of \( \text{Gen}/A \). Let \( (P; \{\pi_j\}_{j \in J}) \) be a fibered product of the family in the topological sense (that is, in \( \text{Top}/A \)). Let \( \mathcal{E} \) consist of all subset elements in \( P \) which are a pullback of a negligible subset element by one of the projections \( \pi_j \). In an obvious sense, a representative for \( \text{Neg}(P, \mathcal{E}) \) will be a product in the category \( \text{Gen}/A \).

Remark 4. The above interpretation enables us to find choices for which the functor can not be represented. Specifically, certain products do not exist in \( \text{Gen} \). Let \( X \) be a real manifold, and consider the usual topological \( X \times X \). It is easily verified that both projections \( X \times X \to X \) are diffuse. Suppose a product \( P \) for \( X \) with itself in \( \text{Gen} \) exists. Then there is a canonical continuous function \( P \to X \times X \) and a canonical \( \text{Gen} \)-morphism \( X \times X \to P \). By general nonsense, these functions are continuous bijections. Thus, \( X \times X \) is a product in \( \text{Gen} \).

Now there must be a diagonal \( \text{Gen} \)-morphism \( \delta : X \to X \times X \) is whose composition with either projection is the identity. Tautologically, this must be the usual diagonal embedding. Alas, by Remark 3, that function is not diffuse.

It is easy to build examples from fibered products instead of a self-product. In general, if \( \Gamma \) is a graph of \( \text{Gen} \)-objects and morphisms, and if \( \alpha : A \to \Gamma \) is an inverse limit for \( \Gamma \) such that every morphism
of $\alpha$ is diffuse, then an inverse limit in $\text{Gen}$ exists only if $\alpha$ is one. Unfortunately, diagonal maps imply that the candidate $\alpha$ will often fail. Indeed, it is difficult to see how a function can have even a self-product unless it is “generically” discrete in some sense.

We can not advance without some non-trivial pullback bases. In this section, we develop one gimmick, which will ultimately allow us to prove something about group quotients. From a pair $(X, \mathcal{E}_0)$, we shall construct a pair $(\Lambda, \mathcal{E}_1)$ and a continuous functor $\lambda : \Lambda \to X$ such that $f \mapsto \lambda \circ f$ induces a natural isomorphism of functors $\text{Neg}(\Lambda, \mathcal{E}_1) \to \text{Neg}(X, \mathcal{E}_0)$.

The construction requires several pages. Fix $X \in \text{Top}$. In what follows, we introduce some temporary terminology, for use just in the construction. In the present context, for each $x \in X$, let $X(x)$ denote the set of open neighborhoods of $x$ in $X$.

Let $CSE(X)$ be the set of all closed subset elements of $X$. In the present context, call a subset $D \subseteq CSE(X)$ closed if the following conditions are true:

(26.a) For $U$ an open subset of $X$, $(U, \emptyset) \in D$.

(26.b) If $(U, I) \in D$ and $V$ is an open subset of $U$, then $(V, V \cap I) \in D$.

(26.c) If $(U, I) \in D$ and $J$ is a subset of $U - I$ for which $(U - I, J) \in D$, then $(U, I \cup J) \in D$.

(26.d) If $(U, I) \in CSE(X)$ and, for each $x \in I$ there exists an open subset $V$ of $U$ for which $(V, V \cap I) \in D$, then $(U, I) \in D$.

Obviously, an arbitrary intersection of closed subfamilies is closed. Thus, given a subset $\mathcal{E} \subseteq CSE(X)$, there is a smallest closed subfamily which contains $\mathcal{E}$. Refer to this as the closure of $\mathcal{E}$, and denote it by $\mathcal{E}^*$.

Let $\mathcal{E}_0 \subseteq CSE(X)$, and let $f : Y \to X$ be a continuous function on a member of $\text{Gen}$ which pulls back each member of $\mathcal{E}_0$ to a negligible subset element. By earlier lemmas, the family of all members of $CSE(X)$ whose pullback under $f$ is negligible is closed. In particular, $f$ pulls back each member of $\mathcal{E}_0^*$ to a negligible subset.

In what follows, assume a family $\mathcal{E}_0 \subseteq CSE(X)$ has been specified, and put $\mathcal{E} = \mathcal{E}_0^*$. Then

(27) $\mathcal{E}$ has properties (26).

In addition, partially order $\mathcal{E}$ be the relation that $(U, I) \leq (V, J)$ if and only if $U \subseteq V$ and $U - I \subseteq V - J$.

Fix $x \in X$. Let $\mathcal{E}(x)$ denote the subset of $(U, I) \in \mathcal{E}$ such that $x \in U$. Let $\Lambda(x)$ denote the set of function $f$ on $\mathcal{E}(x)$ such that
(28.a) for each \((U, I) \in \mathcal{E}(x)\), \(f(U, I)\) is a connected component of \(U - I\) whose closure contains \(x\),

(28.b) for \((U, I), (V, J) \in \mathcal{E}(x)\), \(f(U, I) \subseteq f(V, J)\) if \((U, I) \leq (V, J)\).

It is possible that \(\Lambda(x)\) is empty.

Put

\[
\Lambda = \{(x, f) : x \in X, f \in \Lambda(x)\}.
\]

Define \(\lambda : \Lambda \to X\) by \(\lambda(x, f) = x\). Now we need a topology for \(\Lambda\).

Let \(U\) be an open subset of \(X\). Define

\[
\mathcal{E}[U] = \{I \subseteq U : (U, I) \in \mathcal{E}\}.
\]

For \((x, f) \in \Lambda\) such that \(x \in U\), define

\[
N(U, x, f) = \mathcal{E}[U] = \{(y, g) : y \in U \text{ and } f(U, I) = g(U, I) \text{ for all } I \in \mathcal{E}[U]\}.
\]

We claim next that the family

\[
\{N(U, x, f) : x \in X, U \in X(x), f \in \Lambda(x)\}
\]

is a basis for a topology on \(\Lambda\).

Let \((x, f) \in \Lambda\) and \(U \in X(x)\). Tautologically,

(31.a) \((x, f) \in N(U, x, f)\),

(31.b) \(\lambda(N(U, x, f)) \subseteq U\),

(31.c) for \((y, g) \in N(U, x, f)\), \(N(U, y, g) = N(U, x, f)\).

In addition, if \(V \in X(x)\), it is elementary to check that

\[
N(U \cap V, x, f) \subseteq N(U, x, f) \cap N(V, x, f),
\]

by the nature of connected components. A first consequence of these observations is that \([31]\) is, indeed the basis of a topology on \(\Lambda\). Hereafter, assign to \(\Lambda\) this topology. With that definition in hand, we may also deduce that

(32.a) \(\lambda\) is continuous,

(32.b) for each \(x \in X\), \(\{N(U, x, f) : U \in X(x), f \in \Lambda(x)\}\) is a basis of open neighborhoods at \(x\).

Let

\[
\mathcal{E}_1 = \{\lambda^{-1}\alpha : \alpha \in \mathcal{E}\}.
\]

The next objective is verification that composition with the function \(\lambda\) determines a natural isomorphism \(\text{Neg}(\Lambda, \mathcal{E}_1) \to \text{Neg}(X, \mathcal{E})\).

To begin with, let us expand on \([31]\)b). Let \((x, f) \in \Lambda\), \(U \in X(x)\) and \(I \in \mathcal{E}[U]\). Suppose \((z, h) \in N(U, x, f)\). Now \(f(U, I) = h(U, I)\). By definition, \(z\) lies in the closure of \(h(U, I)\). Thus,

\[
z \in \overline{f(U, I)} \Rightarrow z \in I \text{ or } z \in f(U, I),
\]

(33)
because \( f(U, I) \) is closed in \( U - I \). In other words, the image of \( N(U, x, f) \) under \( \lambda \) lies in \( \overline{f(U, I)} \subseteq f(U, I) \cup I \) for each \( I \in \mathcal{E}[U] \).

Now suppose \( Y \in \textbf{Gen} \) and \( \alpha, \beta : Y \rightarrow \Lambda \) are continuous functions such that \( \lambda \circ \alpha \) and \( \lambda \circ \beta \) pull back each member of \( \mathcal{E} \) to negligible elements. Suppose \( \alpha \neq \beta \). We claim

\[
\lambda \circ \alpha \neq \lambda \circ \beta. \tag{34}
\]

Fix \( y \in Y \) for which \( \alpha(y) \neq \beta(y) \).

If \( \lambda(\alpha(y)) \neq \lambda(\beta(y)) \), we are done. Assume \( x \in X \) such that

\[
\alpha(y) = (x, f) \quad \text{and} \quad \beta(y) = (x, g)
\]

where \( f \neq g \). Take \((U, I) \in \mathcal{E}(x)\) such that \( f(U, I) \neq g(U, I) \). Let \( W \) be the connected component of \( y \) in

\[
\alpha^{-1}N(U, x, f) \cap \beta^{-1}N(U, x, g). \tag{35}
\]

The set

\[
J = (\{ \lambda \circ \alpha \}^{-1}I \cup \{ \lambda \circ \beta \}^{-1}I) \cap W
\]

is negligible in \( W \). The set \( W - J \) is non-empty and connected. Let \( w \in W \). By choice, and by (33), \( \lambda(\alpha(w)) \in f(U, I) \) and \( \lambda(\beta(w)) \in g(U, I) \). But \( f(U, I) \) and \( g(U, I) \) are distinct connected components. Thus, \( \lambda(\alpha(w)) \neq \lambda(\beta(w)) \). We have (34).

Next, suppose that \( Y \in \textbf{Gen} \) and \( \gamma : Y \rightarrow X \) is a continuous function which pulls back members of \( \mathcal{E} \) to negligible elements. For \( y \in Y \), define \( f^y \) on \( \mathcal{E}(x) \), for \( x = \gamma(y) \), as follows. Suppose \((U, I) \in \mathcal{E}(x)\). Let \( W \) be the connected component of \( y \) in \( \gamma^{-1}U \), and let \( J = \gamma^{-1}I \). Then \( W - J \) is a non-empty, connected open set. Let \( f^y(U, I) \) be the connected component of \( U - I \) which contains \( \gamma(W - J) \). Now

\[
W \subseteq \gamma^{-1}(f^y(U, I)) \Rightarrow \gamma(y) \in f^y(U, I).
\]

Trivially, the function \( f^y \) belongs to \( \Lambda(x) \).

Define \( F : Y \rightarrow \Lambda \) by \( F(y) = (\gamma(y), f^y) \). Then \( \lambda \circ F = \gamma \). Now suppose \( y \in Y, (x, f) \in \Lambda, U \in X(x) \) and \( F(y) \in N(U, x, f) \). By (31c), \( N(U, x, f) = N(U, \gamma(y), f^y) \). Let \( W \) be the connected component of \( y \) in \( \gamma^{-1}U \). Now suppose \( w \in W \) and \( I \in \mathcal{E}[U] \). Let \( J = \gamma^{-1}I \), and then \( W - J \) is a non-empty, connected subset. By definition, \( f^y(U, I) \) and \( f^w(U, I) \) are exactly the same! Thus, \( F(w) \in N(U, x, f) \). It follows that \( F \) is continuous.

**Proposition 15.** Let \( X \in \textbf{Top} \) and let \( \mathcal{E}_0 \) be a family of closed subset elements of \( X \). We denote the triple \((\Lambda, \mathcal{E}_1, \lambda)\) constructed above by \((X, \mathcal{E}_0)^\sharp \). Now \( \lambda \) induces a natural transformation from \( \text{Neg}(X, \mathcal{E}_0) \rightarrow \text{Neg}(\Lambda, \mathcal{E}_1) \), and this is an isomorphism of functors.

We now study \( \Lambda \) in certain cases.
Lemma 16. Let \( Y \in \text{Gen} \), let \((U, I)\) be a negligible subset element of \( Y \), and let \( y \in U \). Then there is a unique connected component of \( U - I \) whose closure contains \( y \).

Proof. Let \( W \) be the connected component of \( y \) in \( U \). Then \( y \) is in the closure of the connected, open and closed subset \( W - I \) in \( U - I \). Since \( I \) is negligible, \( W - I \) is connected. \( \square \)

Corollary 10. In the context of Proposition 13, suppose that \( V \subseteq X \) is an open subset such that,

\[
\begin{align*}
& (36.a) \text{ in the subset topology, } V \in \text{LC}, \\
& (36.b) \text{ for each } (U, I) \in E_0, \ (V \cap U, V \cap I) \text{ is a negligible subset element.}
\end{align*}
\]

Then the restriction of \( \lambda \) to \( \lambda^{-1}V \) is a bijection onto \( V \) whose inverse is continuous.

Proof. Clearly, the set of all elements \((U, I)\) such that \((V \cap U, V \cap I)\) is negligible is closed in \( CSE(X) \). Specifically, every member of \( E = E_0^* \) has this property. Let \( \iota : V \rightarrow X \) be the subset injection function. Then there is a unique continuous function \( F : V \rightarrow \Lambda \) such that \( \lambda \circ F = \iota \). To finish, it suffices to show that \( \lambda \) is injective on \( \lambda^{-1}V \).
That is, given \( x \in V \), there is a unique \( f \in E(x) \). But this is immediate by Lemma 10. \( \square \)

Lemma 17. In the context of Proposition 13, if \( X \) is Hausdorff, then \( \Lambda \) is Hausdorff.

Proof. Let \( p \) and \( q \) be distinct points in \( \Lambda \). We must show that \( p \) and \( q \) can be separated by open neighborhoods. If \( \lambda(p) \neq \lambda(q) \), this is trivial. Assume \( x \in X \), \( p = (x, f) \) and \( q = (x, g) \) for \( f \neq g \).
Assume that \((U, I) \in E \) such that \( f(U, I) \neq g(U, I) \). Suppose \((z, h) \in N(U, x, f) \cap N(U, x, g) \). Then
\[
f(U, I) = h(U, I) = g(U, I)
\]
which would contradict choice of \((U, I)\). \( \square \)

Proposition 18. In the context of Proposition 13, assume that \( K \) is a closed subset of \( X \) and that \( V = X - K \) satisfies \((36.a,b)\). Assume also that \((X, K) \in E_0 \). Then \( \Lambda \) is locally connected and \( \lambda^{-1}K \) is a negligible subset. Moreover, if \( E \) contains all negligible subset elements \((U, I)\) in \( \Lambda \), then, with respect to \( \lambda \), \( \Lambda \) represents \( \text{Neg}(X, E_0) \).
Proof. For each \( x \in X - K \), let \( x^* \) denote the unique member of \( \lambda^{-1}\{x\} \).

Let \( (x, f) \in \Lambda \) and \( U \in X(x) \). Put \( W = f(U, U \cap K) \). For each \( I \in \mathcal{E}[U] \), \( W - I \) is connected. Since \( (U, (U \cap K) \cup I) \leq (U, U \cap K) \), we get that

\[
\{w^* : w \in f(U, U \cap K)\} = N(U, x, f) \cap \lambda^{-1}(X - K).
\]

The same reasoning applies to \( (U, (U \cap K) \cup I) \leq (U, I) \). The set \( f(U, I) \) is uniquely characterized as the only connected component of \( U - I \) which intersects \( W - I \). Now let \( w \in W \). Working directly from the definition, we get that \( w^* \in N(U, x, f) \). It follows easily that

\[
\{w^* : w \in f(U, U \cap K)\} = N(U, x, f) \cap \lambda^{-1}(X - K).
\]

Recall that \( f(U, U \cap K) \) is non-empty.

We draw several conclusions. First, \( \lambda^{-1}(X - K) \) must be dense in \( \Lambda \). Second, suppose \( (x, f) \in \Lambda \) and \( U \in X(x) \). Then \( N(U, x, f) \cap \lambda^{-1}(X - K) \) is a dense, connected subset of \( N(U, x, f) \). Thus, \( N(U, x, f) \) is connected.

We have proved that \( \Lambda \) is locally connected and that \( \lambda^{-1}K \) is nowhere dense. In addition, for each \( r \in \lambda^{-1}K \), we have found that, for each \( U \in X(\lambda(r)) \), \( N(U, r) \) is an open, connected neighborhood such that \( N(U, r) - \lambda^{-1}K \) is also connected. By Lemma \( \ref{lem:connectedness} \), the set \( \lambda^{-1}K \) is negligible. Consequently, \( \mathcal{E}_1 \) contains only negligible subset elements.

Finally, suppose that \( \mathcal{E} \) contains all negligible subset elements \((U, I)\) in which \( U \subseteq X - K \). If \((U, I)\) is a negligible subset element of \( \Lambda \), it is elementary to check that \((U, I)\) belongs to \( \mathcal{E}_1^* \). It follows that \( \Lambda \), as a Gen-object, represents \( \text{Neg}(X, \mathcal{E}_0) \). \( \square \)

Corollary 11. Let \( b : B \rightarrow A \) be a Gen-morphism. Let \( I \subseteq B \) be a negligible subset, and assume that the restriction of \( b \) to \( B - I \) is, in the usual sense, an open local homeomorphism. Then \( b \) is a pullback base in Gen.

In fact, we can give a construction for pullbacks. Let \( c : C \rightarrow A \) be a Gen-morphism. Let \((X; \pi_C, \pi_B)\) be a pullback \( c^{-1}(B, b) \) with respect to the category Top. Let \( K = \pi_B^{-1}I \). Let \( \mathcal{D} \) be the set of all negligible subset elements of \( X - K \), and let \( \mathcal{E}_0 = \mathcal{D} \cup \{(X, K)\} \). Let \((\Lambda, \mathcal{E}_1, \lambda) = (X, \mathcal{E}_0)^\# \). Then \((\Lambda; \pi_C \circ \lambda, \pi_B \circ \lambda)\) is a pullback \( c^{-1}(B, b) \), with respect to Gen.

Proof. Let us justify the construction of \( c^{-1}(B, b) \). First, observe that the restriction of \( \pi_C \) to \( X - K \) is an open local homeomorphism. Thus, \( X - K \in \text{LC} \).
Let $\mathcal{N}$ be the class of negligible subset elements of $C$. Since negligibility is a local property, it follows that for $(U, I) \in \mathcal{N}$, $((\pi_C^{-1}U) - K, I - K)$ is negligible. In other words, every subset element of $X - K$ which belongs to $(\pi_C^{-1}\mathcal{N})^*$ is negligible. Just as importantly, the fact that $\pi_C$ is a local homeomorphism implies that $(\pi_C^{-1}\mathcal{N})^*$ contains every negligible subset element of $X - K$.

We can find an open cover for $B - I$ such that, on each member, $b$ restricts to an open embedding. Consequently, there is an open cover of $X - K$ such that $\pi_B$, restricted to each, identifies with a restriction of $c$ to a subset of $C$. By Corollary 3 the restriction of $\pi_B$ to $X - K$ is diffuse.

Verification that $\Lambda$ has the fibered product property is now trivial. □

5. Quotients and the Pseudoétale Property

We are ready to use the material of [6, Section 8]. We assume the notational conventions and theorems of that work, with one caveat. In that paper, the words “open”, “discrete”, “finite” and several others have categorical definitions. In the topological context, these terms have more standard, concrete meaning. In general, when using a term, we mean it in the topological sense. To indicate when an ambiguous term is intended in the universal sense, we prefix it with “c-”.

Let $\textbf{Aux}$ be the class of tuples $(G, \rho, B, b, A)$ in which

- $(37.a)$ $B \in \text{Top},$
- $(37.b)$ $(G, \rho)$ is a finite group action on $B$, with respect to $\text{Top},$
- $(37.c)$ $b : B \to A$ is an open, continuous surjection, and
- $(37.d)$ for $x, y \in B$, $b(x) = b(y)$ if and only if $x$ is in the $G$-orbit of $y$.

Note that given a group action $(G, \rho)$ on a topological space $B$, then the standard topological quotient construction produces such a function $b$.

In the present context, for $g \in G$ and $x \in B$, we write $g \cdot x$ for $\rho(g)(x)$.

Let $(G, \rho, B, b, A) \in \textbf{Aux}$. Let $U$ be the set of $x \in B$ which have a neighborhood $V$ such that $g \cdot V \cap V = \emptyset$ for every $g \in G - \{e\}$. Obviously, $U$ is open and $G$-invariant. In the present Section, refer to the complement of $U$ as the upper ramification set, and refer to the image of the complement under $b$ as the lower ramification set. Clearly, both ramification sets are closed in their respective spaces. Note that the restriction of $b$ to $U$ is a local homeomorphism.

The remainder of the section is dedicated to proof of the following
Theorem 19. Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{Gen}\) and that the upper ramification set is negligible. Also, suppose that if \(x \in B\) and \(g \in G\), then either \(g \cdot x = x\) or \(x\) and \(g \cdot x\) can be separated by open sets. Then \(b\) is a pseudoétalement \(\text{Gen}\)-morphism.

Proof will require several lemmas.

Let us begin with some point-set topology. Let \((G, \rho, B, b, A) \in \text{Aux}\). Let \(K\) be the upper ramification set, and assume that \(B - K \in \text{LC}\). Put \(I = b(K)\). Suppose \(V\) is an open, connected, non-empty subset of \(A - I\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.

Let \((G, \rho, B, b, A) \in \text{Aux}\). Suppose that \(B \in \text{LC}\) and that the upper ramification set \(K\) is negligible in \(B\). Since \(b\) is open, \(A \in \text{LC}\). Put \(I = b(K)\). Let \(V\) be an open, connected, non-empty subset of \(A\), and let \(W\) be a connected component of \(b^{-1}V\). By elementary methods, it follows that

\[(38.a)\quad b(W) = V,\] and
\[(38.b)\quad b^{-1}V = \bigcup_{g \in G} g \cdot W.\]

We shall use this observation repeated.
Let \((G, \rho, B, b, A) \in \text{Test}\), and let \(c : C \to A\) be a \text{Gen}-morphism. Let \((X; \pi_C, \pi_B)\) be pullback \(c^{-1}(B, b)\) in the category \(\text{Top}\), and let \((\Lambda, \mathcal{E}_1, \lambda)\) be the construction in Corollary \[\text{I}]. As a pullback in \(\text{Top}\), \(X\) supports a canonical action by \(G\); as a pullback in \(\text{Gen}\), \(\Lambda\) supports a canonical action. The action by \(g \in G\) on \(\Lambda\) can be characterized as the unique \(\text{Gen}\)-morphism \(f\) such that \(\lambda(f(x)) = g \cdot \lambda(x)\) for all \(x \in \Lambda\).

Tautologically, the upper ramification set of \(\Lambda\) will be a closed subset of the pullback of the upper ramification set of \(B\). Hence, the former is negligible. To proceed, we need one more fact: that \(\pi_C \circ \lambda\) is a quotient map for the action on \(\Lambda\).

Let \(K\) be the upper ramification set for the action of \(G\) on \(X\). Let \(d = \pi_C\), and let \(J = d(K)\). It is known that \(X - K \in \text{LC}\) and that \(J\) is closed. By inspection, \(d\) is a quotient for action of \(G\) on \(X\). Moreover, the lower ramification set for \(d\) lies in the pullback of the lower ramification set for \(b\); therefore, both are negligible. In addition, by inspection, members of a \(G\)-orbit in \(X\) can be separated by open sets.

The behavior of \(\lambda\) away from \(K\) is trivial. To finish the present step, we must show

(39.a) the function \(d \circ \lambda\) is locally open at each \(y \in \lambda^{-1}K\), and
(39.b) for each \(x \in K\), \(\lambda^{-1}\{x\}\) is a non-empty set of elements in the same \(G\)-orbit.

First, we describe the action by \(G\) on \(\Lambda\) explicitly. For \(g \in G\) and \((x, f) \in \Lambda\), define \(g \cdot (x, f)\) to be \((g \cdot x, h)\) where \(h\) is defined by \(h(U, I) = g \cdot f(U, I)\). By inspection, for a fixed \(g \in G\), \((x, f) \mapsto g \cdot (x, f)\) is a continuous function which satisfies the necessary commutation.

For the moment, fix \(x \in X\). Suppose \(U \in X(x)\). Now \(d(U)\) is connected and open, as must be \(d(U) - J\). Let \(M\) be a connected component of \(d^{-1}(d(U) - J)\). All components are \(G\)-conjugates of \(M\). The union of elements \(g \cdot M\) over \(G\) is a \(G\)-invariant closed set, and so its image is a closed set. That image contains all of \(d(U)\). Consequently, for any \(y \in U\), there is a component whose closure contains \(y\). Use \(y = x\), and, without loss of generality, we may assume \(x \in M\). Let \(\Omega(U)\) be the set of connected components of \(d^{-1}(d(U) - J)\) whose closures contain \(x\).

Since \(U\) is symmetric, we know that \(U\) itself is a connected component of \(d^{-1}d(U)\). Consequently, every member of \(\Omega(U)\) is contained in \(U\). Now for \(g \in G\), we see that either \(g \in G(x)\), in which case \(g\) permutes the members of \(\Omega(U)\), or \(g \notin G(x)\), in which case \(g \cdot M\) is disjoint from \(U\). It follows that \(U - K\) is exactly the disjoint union of the members of \(\Omega(U)\).
For each $U \in X(x)$, the size of $|\Omega(U)|$ is bounded above by $G(x)$. Therefore, we may choose $U_0 \in X(x)$ for which $|\Omega(U_0)|$ is maximal. That is,

$$|\Omega(U_0)| = \max\{|\Omega(U)| : U \in X(x)\}$$  \hspace{1cm} (40)

Then, for each $V \in X(x)$ such that $V \subseteq U_0$, it is easily checked that

(41) The rule $M \mapsto M \cap V$ defines a bijection $\Omega(U_0) \to \Omega(V)$.

Once this claim is accepted, it is easily argued that

(42) For each $M \in \Omega(U_0)$, there is a unique member $f_M \in \Lambda(x)$

with the property that $f_M(U_0, U_0 \cap K) = M$.

An immediate corollary is that the function $M \mapsto (x, f_M)$ is $G(x)$-equivariant. Condition (39.b) follows.

Let us draw one more conclusion.

(43) For $x \in X$, $U \in X(x)$, and for $M$ a connected component of

$U - K$, there is some $f \in \Lambda(x)$ such that $f(U, U \cap K) = M$.

Proof is left to the reader.

It remains to show that $d \circ \lambda$ is locally open. Let $(x, f) \in \Lambda$, and let $U \in X(x)$. It suffices to show that $d \circ \lambda(N(U, x, f))$ is open in $C$.

The image $d(U)$ is known to be open. Thus, it suffices to show that $d \circ \lambda(N(U, x, f)) = d(U)$. That is, for each $y \in U$, we must find an $h \in \Lambda(y)$ and $g \in G$ such that $g \cdot (y, h) \in N(U, x, f)$.

Suppose $y \in U$. We have already observed that every member of $U$ lies in the closure of a $G(x)$-conjugate of $M = f(U, U \cap K)$. We are free to replace $y$ by any $G$-conjugate; hence, assume that $y$ lies in the closure of $M$.

Let $V \in X(y)$ be a symmetric neighborhood such that $V \subseteq U$. By (43), there is $h \in \Lambda(y)$ such that $h(U, U \cap K) = M$. It is clear that $h(U, I) = f(U, I)$ for every $I \in \mathcal{E}[U]$. Thus, $(y, h) \in N(U, x, f)$.

At this point, we may legitimately state that

(44) The class $\mathbf{Test}$ satisfies $\mathbf{[B]} (59.A,B,C)]$.

Let us turn to condition (D).

Let $(G, \rho, B, b, A) \in \mathbf{Test}$. Let $Y \in \mathbf{Gen}$ be non-empty and connected, and let $\alpha, \beta : Y \to B$ be two $\mathbf{Gen}$-morphisms such that $b \circ \alpha = b \circ \beta$. Let $K$ be the upper ramification set of $B$. Then the subset $Y_1 = Y - (\alpha^{-1}K) - (\beta^{-1}K)$ is non-empty, connected, and dense in $Y$. Choose and $y \in Y_1$. Then there is a unique $g \in G$ such that $g \cdot \alpha(y) = \beta(y)$. As the restriction of $b$ to $B - K$ is a local homeomorphism, and since $Y_1$ is connected, it follows that $g \cdot \alpha(y) = \beta(y)$ for all $y \in Y_1$. Now, for $y \notin Y_1$, the hypothesis that two distinct members of $\alpha(y)$’s orbit can be separated by open sets will rule out the possibility
that \( g \cdot \alpha(y) \neq \beta(y) \). (This elementary step uses the fact that \( Y_1 \) is dense.) This finishes [3, (59.D)].

We now have a family of quotients which satisfies the hypothesis of [3, Lemma 46]. Let \((G, \rho, B, b, A) \in \textbf{Test}\). Let \( u : U \to B \) be an open embedding. Corollary [3] states that \( b \) is open in the traditional sense. Let \( w : W \to A \) be an open embedding whose image, in the usual sense, is the image of \( b \circ u \). Then a pullback of this \( w \) will be an open embedding whose image is the set of all \( x \in B \) which are \( G \)-conjugate to something in the image of \( u \). Consequently, this choice of \( w \) meets condition [3, (60)]. Therefore, by [3, Corollary 47], every member of \textbf{Test} is a perfect quotient.

At this point, Theorem [3] is a special case of [3, Theorem 51].

6. LIFTING FAITHFUL FUNCTORS

Let \( \mathcal{M} \) be a category of orbifolds which comes with a topological model. In our language, this means there is a chosen continuous functor \( \Gamma : \mathcal{M} \to \text{Gen}[S] \) for some set \( S \). The functor \( \Gamma \) is rarely full. That is, if \( X, Y \) are topological spaces identified with orbifolds, then one does not expect that every continuous \( f : X \to Y \) will lift to a morphism of orbifolds. However, in many situations, \( \Gamma \) is expected to be faithful. That is, if \( f, g : M \to N \) are two morphisms of orbifolds such that \( \Gamma(f) = \Gamma(g) \), then \( f = g \). Informally, we say \( f \) and \( g \) are equal if their “underlying” functions agree.

In our present program, a useful category \( \mathcal{M} \) appears as the expansion of an initial category \( \mathcal{C} \)—that is, \( \mathcal{M} = \mathcal{C}^+, \mathcal{C}^{++} \), or some higher iterate of the plus construction. On the initial \( \mathcal{C} \), it should be clear, by inspection, that \( \Gamma \) is faithful. In this section, we prove that all the lifts of \( \Gamma \) are faithful, under a reasonable hypothesis.

Our standing hypothesis is

(45) Let \( \mathcal{C} \) be a topologized category which satisfies [3, (11)]. Let \(+ : \mathcal{C} \to \mathcal{C}^+\) be a plus construction, and let \( p \) and \( s \) denote the component pasting and smoothing functors, respectively. Regard \( \mathcal{C}^p \) as topologized in the usual way.

Let us begin with an elementary reduction.

**Lemma 20.** Assume (43). Let \( \mathcal{E} \) be a topologized category and let \( \Gamma : \mathcal{C}^+ \to \mathcal{E} \) be a covariant functor. Assume that \( \mathcal{E} \) is quasi-intrinsic, in the sense of [3, Definition 12.5], and that \( \Gamma \circ s \) is continuous. Then \( \Gamma \) is faithful if and only if for each \( B \in \mathcal{C} \) and each \( A_0 \in \mathcal{C}^p \), the function

\[
\text{Mor}_{\mathcal{C}^p}(B^p, A_0) \to \text{Mor}_{\mathcal{E}}(\Gamma(B^+), \Gamma(A_0))
\]

defined by \( \Gamma \), is injective.
Figure 1. Plus Morphisms as Maps between Canopies

Proof. Let $A_0, B_0 \in \text{Obj}(\mathcal{C}^+) = \text{Obj}(\mathcal{C}^\prime)$. Let $f_1, g_1 : B_0 \to A_0$ be $\mathcal{C}^+$-morphisms. Then there exist $\mathcal{C}^\prime$-morphisms

\[
x_0 : X_0 \to B_0, \quad f_0 : X_0 \to A_0, \\
y_0 : Y_0 \to B_0 \quad \text{and} \quad g_0 : Y_0 \to A_0,
\]

such that $x_0$ and $y_0$ are pseudoisomorphisms and

\[
f_0^s = f_1 \circ x_0^s \quad \text{and} \quad g_0^s = g_1 \circ y_0^s.
\]

Let $((P, p_0); r_0, t_0)$ be a fibered product $(X_0, x_0) \times_{B_0} (Y_0, y_0)$ in $\mathcal{C}^\prime$. Then $p_0, r_0$ and $t_0$ are all pseudoisomorphisms and

\[
\{f_0 \circ r_0\}^s = f_1 \circ p_0^s \quad \text{and} \quad \{g_0 \circ t_0\}^s = g_1 \circ p_0^s.
\]

Smoothing takes $p_0, r_0$ and $t_0$ to isomorphisms. Thus, $\Gamma(f_1) = \Gamma(g_1)$ if and only if $\{\Gamma \circ s\}(f_0 \circ r_0) = \{\Gamma \circ s\}(g_0 \circ t_0)$.

It follows that $\Gamma$ is faithful if and only if $\Gamma \circ s$ is faithful.

Let $A_0, B_0 \in \mathcal{C}^\prime$ and let $f_0, g_0 \in \text{Mor}_{\mathcal{C}^\prime}(B_0, A_0)$. If $f_0 \circ \iota_j = g_0 \circ \iota_j$ for each $j \in \Lambda(B_0)$, then $f_0 = g_0$. Now $\Gamma \circ s$ is continuous, so it sends the assigned cover to $B_0$ to an $\mathcal{E}$-cover. Since the topology of $\mathcal{E}$ is quasi-intrinsic, it is also true that if $\Gamma(f_0) \circ \Gamma(\iota_j) = \Gamma(f_0 \circ \iota_j)$ and $\Gamma(g_0) \circ \Gamma(\iota_j) = \Gamma(g_0 \circ \iota_j)$ agree for every $j$, then $\Gamma(f_0) = \Gamma(g_0)$. The desired conclusion follows.

For convenience, we introduce a term for use in this section only. Let $\mathcal{D}$ be a topologized category. We say $\mathcal{D}$ meets the $m$-hypothesis if the following two conditions are true.

(46.a) Every formal $\mathcal{D}$-subset $b$ can be decomposed as $b = w \circ f$ where $w$ is a monomorphic formal subset and $f$ overlays absolutely. (Recall that, in this situation, $f$ is a pullback for $b$.)

(46.b) Let $\theta$ be an indexed cone of formal $\mathcal{D}$-subsets into an object $X$. Then the canopy of $\theta$ admits an affinization.

Condition (46.b) is [3, (9.c)], albeit in a more general context.

Proposition 21. Assume [3].
We sketch the proof. Details are in the style of [3].

Proof. We begin with (46.a). Let $b_1 : B_0 \rightarrow A_0$ be a monomorphic e.l.-subset. We are free to replace $b_1$ by any morphism $C^+/A^+$-isomorphic to it. Thus, we may assume that $b_1 = b_0^+$ where $b_0 : B_0 \rightarrow A_0$ is a $C^p$-morphism such that, for each $j \in \Lambda(B_0)$, $b_0 \circ \iota_j$ is a formal $C^p$-subset. Now a product of two affine formal subsets is known to be affine. It follows that there is a $C^p$-morphism $w_0 : W_0 \rightarrow A_0$ such that

(47.a) $\Lambda(W_0) = \Lambda(B_0)$,
(47.b) for each $j \in \Lambda(W_0)$, $w_0 \circ \iota_j = b_0 \circ \iota_j$, and
(47.c) for $(j, k) \in \Lambda(B_0)^2$, the image of $(W_0[j, k]; \rho_1, \rho_2)$ under pasting is a product $\{b_0 \circ \iota_j\} \times_{A_0} \{b_0 \circ \iota_k\}$.

It follows that

(48.a) $w_0^+$ is a monomorphic e.l.-subset,
(48.b) there is a morphism $f_0 : B_0 \rightarrow W_0$ such that, for each $j \in \Lambda(W_0)$, $f_0 \circ \iota_j = \iota_j$,
(48.c) $f_0^+$ is an e.l.-subset which covers.

Thus, $b_0^+ = w_0^+ \circ f_0^+$ is a decomposition of the required type.

Let us interpolate a proof of Part (B). In the present context, suppose that $C$ meets the m-hypothesis and that $A_0 = A^p$ where $A \in \mathcal{C}$. Then $W_0$ is a canopy of a cone of formal $C$-subset. By assumption, it admits an affinization in $C$. Let $w$ be the affinization of $w_0$. Then $w$ is a monomorphic local subset. By condition [3, 11.D], $w$ is a local subset.

Now return to Part (A). Suppose $A_0 \in C^+$ and $\theta$ is a cone of e.l.-subsets into $A_0$ indexed by a set $T$. Again, we may assume without loss of generality that for each $t \in T$, $\theta(t) = b_0^+$ where $\theta(b_0) : \theta_0 \rightarrow A_0$ is a $C^p$-morphism such that $\theta_0 \circ \iota_j$ is a formal $C^p$-subset for each $j \in \Lambda(\theta_0)$. Put

$J = \{(t, j) : t \in T, j \in \Lambda(\theta_0)\}$.

There is $U_0 \in C^p$ of type $\mathrm{Int}(J)$ and a $C^p$-morphism $u_0 : U_0 \rightarrow A_0$ for which

(49.a) for each $(t, j) \in J$, $u_0 \circ \iota_{(t,j)} = \theta_0 \circ \iota_j$,
(49.b) for each pair $((t, j), (r, k)) \in J^2$, the image of $(U_0[(t, j), (r, k)]; \rho_1, \rho_2)$ under the pasting functor is a fibered product $\{\theta_0 \circ \iota_j\} \times_{A_0} \{\theta_0 \circ \iota_k\}$.
For each \( t \in T \), there is a unique \( C^p \)-morphism \( {}^t p_0 : {}^t B_0 \to U_0 \) such that, for each \( j \in \Lambda({}^t B_0) \), \( {}^t p_0 \circ {}_{(t,j)} = {}_{(t,j)} \). Then \( t \mapsto {}^t p_0 \) is an affinization for \( \theta \) in \( C^+ \). \( \square \)

Let us recall some facts and comments from [5]. Let \( \mathcal{D} \) be a topologically componentwise category whose topology is intrinsic and flush. In \( \mathcal{D} \), a morphism whose domain is connected is said to be “connected”; similarly, it is called non-empty if its domain is “non-empty”. A decomposition into connected component of an object \( A \) is an indexed family \( \theta \) of complemented morphisms into \( A \) for which

(50.a) \( \theta \) is a cover, and

(50.b) for \( j, k \in \text{dom}(\theta) \) such that \( j \neq k \), the product \( \theta(j) \times_A \theta(k) \) is empty,

(50.c) for each \( j \in \text{dom}(\theta) \), the domain of \( \theta(j) \) is connected and non-empty.

Recall from [5] that, in such a category, every object with a cover by connected morphisms admits a decomposition into connected components.

Lemma 22. Let \( \mathcal{C} \) and \( \mathcal{E} \) be topologized categories. Assume both are intrinsic and topologically componentwise. By a topologically componentwise functor from \( \mathcal{C} \to \mathcal{E} \), we mean a continuous functor \( \Gamma \) from \( \mathcal{C} \) to \( \mathcal{E} \) such that

(51.a) \( \Gamma \) sends empty \( \mathcal{C} \)-objects to empty \( \mathcal{E} \)-objects,

(51.b) \( \Gamma \) sends non-empty connected \( \mathcal{C} \)-objects to non-empty connected \( \mathcal{E} \)-objects.

Let \( \Gamma : \mathcal{C} \to \mathcal{E} \) be a topologically componentwise functor. Assume that every \( \mathcal{C} \)-object has a cover by connected morphisms.

(A) \( \Gamma \) sends complemented \( \mathcal{C} \)-morphisms to complemented \( \mathcal{E} \)-morphisms.

(B) \( \Gamma \) sends non-empty objects to non-empty objects.

(C) Let \( \theta \) be a decomposition into connected components of an object \( A \in \mathcal{C} \). Then \( \Gamma \circ \theta \) is a decomposition into connected components of \( \Gamma(A) \).

Proof. Every \( \mathcal{C} \)-object has a decomposition into connected components. Thus, every non-empty \( \mathcal{C} \)-object is a the codomain of a connected morphism. It follows that \( \Gamma \) sends non-empty objects to non-empty objects.

In either \( \mathcal{C} \) or \( \mathcal{E} \), a complemented morphism can be characterized as a morphism \( b : B \to A \) such that

(52.a) \( b \) is a formal subset,
(52.b) \((B; 1_B, 1_B)\) is a self-product \(b \times_A b\),
(52.c) there is another morphism \(c : C \to A\) which satisfies (a) and
(b) and for which \(b \times_A c\) is empty and \(\{b, c\}\) is a cover.

These properties are preserved by \(\Gamma\). Part (A) follows. Part (C) is an
easy consequence. □

**Theorem 23.** Assume \((\mathcal{T})\). Let \(\mathcal{E}\) be a topologized category, and let
\(\Gamma : \mathcal{C}^+ \to \mathcal{E}\) be a covariant functor. Assume

(53.a) \(\mathcal{C}\) is topologically componentwise and every \(\mathcal{C}\)-object has
\hspace{1cm} a cover by connected \(\mathcal{C}\)-morphisms,
(53.b) every formal \(\mathcal{C}\)-subset is discrete,
(53.c) \(\mathcal{C}\) satisfies the m-hypothesis,
(53.d) the topology of \(\mathcal{E}\) is intrinsic, flush and topologically componentwise,
(53.e) every formal \(\mathcal{E}\)-subset is discrete,
(53.f) \(\Gamma \circ +\) is faithful and topologically componentwise,
(53.g) \(\Gamma \circ s\) is continuous,
(53.h) for \(b\) a formal \(\mathcal{C}\)-subset, if \(\Gamma(b^+)\) is an \(\mathcal{E}\)-isomorphism,
\hspace{1cm} then \(b\) is a \(\mathcal{C}\)-isomorphism.

Then

(54.a) \(\Gamma\) is a faithful functor, and it sends connected \(\mathcal{C}^+\)-objects
\hspace{1cm} to connected \(\mathcal{E}\)-objects,
(54.b) if \(b : B \to A\) is a formal \(\mathcal{C}\)-subset and \(c : C \to A\)
\hspace{1cm} is an arbitrary \(\mathcal{C}\)-morphism with connected domain, then the
\hspace{1cm} function induced by \(\Gamma\)
\hspace{1cm} \[
\text{Mor}_{\mathcal{C}/A}(C, c; B, b) \to \text{Mor}_{\mathcal{E}/\Gamma(A)}(\Gamma(C, c), \Gamma(B, b))
\]
\hspace{1cm} is a bijection,
(54.c) if \(b\) is an e.l.-subset such that \(\Gamma(b)\) is an \(\mathcal{E}\)-isomorphism,
\hspace{1cm} then \(b\) is a \(\mathcal{C}^+\)-isomorphism.

**Remark 5.** In practice, attention is limited to topologies meeting an
explicit list of axioms. The theorem applies to topologies which are
flush, intrinsic, topologically componentwise and such that every formal
subset is discrete. In a practical situation, there would be a canonical
choice of topology for \(\mathcal{C}^+\), related to the e.l.-topology, with respect to
which \(\Gamma\) is continuous. In this context, conditions \((\mathcal{E}a,b,c,d,e,g)\) are
true by fiat or by elementary arguments (e.g., using the fact that the
e.l.-topology meets the m-hypothesis to show that the chosen topology of
\(\mathcal{C}^+\) meets the same condition). The “real” hypothesis is \((\mathcal{E}f,h)\). The
theorem says that if the hypothesis holds for \(\mathcal{C}\), it will hold for \(\mathcal{C}^+\).
Proof. The conclusions of Lemma 22 apply to \( \Gamma \) by (53.g).

Let \( A_0 \) be a connected \( C^+ \)-object. For each \( j \in \Lambda(A_0) \), let \( \phi_j \) be a decomposition of \( A_0[j] \) into connected components. Let \( \lambda \) be the refinement of the assigned cover through \( j \mapsto \phi_j \), and let \( \Omega \) be the domain of \( \lambda \). Note that no member of \( \lambda \) is empty. On \( \Omega \), define the linking relation, as in [4]. That is, define \( \sim \) on \( \Omega \) to be the smallest equivalence relation such that \( r \sim s \) when \( \lambda(r) \times_{A_0} \lambda(s) \) is non-empty.

We now refine results from [4]. Since \( A_0 \) is connected in \( C^+ \), all members of \( \Omega \) are equivalent under \( \sim \). By Lemma 22, the image of \( \lambda \) under \( \Gamma \circ \sim \) is a connected cover of \( \Gamma(A_0) \). Define \( \approx \) on \( \Omega \) to be the smallest equivalence relation such that \( r \approx s \) when \( \Gamma(\lambda(r)) \times_{\Gamma(A_0)} \Gamma(\lambda(s)) \) is non-empty. Recall that \( \Gamma \circ \sim \) is continuous by assumption. It follows that \( \approx \approx \sim \approx \), and that all members of \( \Omega \) are equivalent. Therefore, \( \Gamma(A_0) \) is connected.

Let \( B \in C \), \( A_0 \in C^p \) and \( f_0, g_0 \in \text{Mor}_{C^p}(B^p, A_0) \) such that \( \Gamma(f_0) = \Gamma(g_0) \). Take \( j, k \in \Lambda(A_0) \) and \( C \)-morphisms \( f : B \rightarrow A_0[j] \) and \( g : B \rightarrow A_0[k] \) such that \( f_0 = \iota_j \circ f^p \) and \( g_0 = \iota_k \circ g^p \). Since \( \Gamma \circ \sim \) is a continuous functor, \( (\Gamma(A_0[j, k]); \Gamma(p_1), \Gamma(p_2)) \) is a fibered product \( \Gamma(\iota_j) \times_{\Gamma(A_0)} \Gamma(\iota_k) \). Since \( \Gamma(g_0) = \Gamma(\iota_k) \circ \Gamma(g^+) \) and \( \Gamma(f_0) = \Gamma(\iota_j) \circ \Gamma(f^+) \) agree, there is an \( E \)-morphism \( H : \Gamma(B) \rightarrow \Gamma(A_0[j, k]) \) such that \( \Gamma(p_1) \circ H = \Gamma(f^+) \) and \( \Gamma(p_2) \circ H = \Gamma(g^+) \). By Lemma 20, to prove that \( \Gamma \) is faithful it suffices to show that, in this situation, \( H = \Gamma(h) \) for some \( C \)-morphism \( h : B \rightarrow A_0[j, k] \). Thus, (54.a) will be true if (54.b) holds.

Let us turn to (54.b). We begin with a comment equally applicable to \( C \) and \( E \).

Let \( D \) be any componentwise category. Let \( b : B \rightarrow A \) be a discrete pullback base, let \( C \) be a connected object, and let \( c : C \rightarrow A \) be a \( D \)-morphism. Let \((P;p,q)\) be a pullback \( c^{-1}(B,b) \). It is known, from [4], that there is a bijection from the set \( S \), of \( D/A \)-morphisms \( f : (C,c) \rightarrow (B,b) \), to the set \( T \), of connected components of \( P \) on which \( p \) is an isomorphism, which assigns to each \( f \in S \) the connected component of \( P \) through which \( 1_C \times f \) factors.

Suppose \( b : B \rightarrow A \) is a formal \( C \)-subset, \( c : C \rightarrow A \) is a connected morphism and \((P;p,q)\) is a pullback \( c^{-1}(B,b) \). The functor \( \Gamma \) preserves these relations and sends components of \( P \) to components of its image. The map in (54.b) can fail to be bijective only if there is a connected component of \( x : X \rightarrow P \) such that \( p \circ x \) is not a \( C \)-isomorphism but \( \Gamma(p \circ x) \) is an \( E \)-isomorphism. The latter is explicitly disallowed by assumption (53.h).

Conclusions (54.a,b) have been verified. The last is comparatively simple. Suppose \( b_1 : B_0 \rightarrow A_0 \) is an e.l.-morphism for which \( \Gamma(b_1) \) is
an isomorphism. Let \( \theta \) be an affine \( \mathcal{C}^p \)-cover of \( A_0 \). To show that \( b_1 \) is an isomorphism, it suffices to prove that each pullback along a member of \( \theta \) is an isomorphism. Hence, we may assume that \( A_0 = A^+ \) for some \( A \in \mathcal{C} \).

It is known that \( \Gamma \) is faithful. Thus, if \( b_1 \) is not monomorphic in \( \mathcal{C}^+ \), its image cannot be monomorphic. Therefore, \( b_1 \) is a monomorphic e.l.-subset into an affine object. From Proposition 21, it follows that \( b_1 \) is isomorphic to a formal \( \mathcal{C} \)-subset. By hypothesis (53.g), \( b_1 \) is an isomorphism. \( \square \)

7. WHAT IS A MORPHISM?

Let \( M \) and \( N \) be two \( C^\infty \)-manifolds. Let \((G, \sigma)\) and \((H, \tau)\) be finite group actions on \( M \) and \( N \) respectively, which are discrete with respect to diffuse \( C^\infty \)-functions between manifolds. This Section discusses the specific issue of what is a morphism between the quotient spaces \( G \backslash M \rightarrow H \backslash N \). For us, this amounts to looking at the abstract machinery and rewriting the formal definition in this explicit case. Irregularities and surprising behaviors have been noted in explicit situations. We offer our spin on a pathological situation discussed by Schwarz in [13].

To begin, let us lay out the above situation in the abstract. Let \( \mathcal{M} \) be a category which is being used to generate orbifolds. That is,

- \((55.a)\) \( \mathcal{M} \) is a topologized category,
- \((55.b)\) the topology of \( \mathcal{M} \) is flush, intrinsic and topologically component-wise,
- \((55.c)\) every \( \mathcal{M} \)-object has a cover by connected objects,
- \((55.d)\) the topology of \( \mathcal{M} \) is pseudoétaile (or torsorial); that is, a local \( \mathcal{M} \)-subset which is discrete and finite (respectively, just discrete) must be a formal \( \mathcal{M} \)-subset,
- \((55.e)\) \( \mathcal{M} \) meets the set-theoretic axioms in [3, (11)].

By assigning to \( \mathcal{M}^+ \) the class of discrete (and, depending on context, finite) e.l.-subsets, we arrange for \( \mathcal{M}^+ \) to meet the same axioms. Thus, the fundamental construction generates a sequence of enlargements \( \mathcal{M}, \mathcal{M}^+, (\mathcal{M}^+)\),... whose members are orbifolds. Assume \( S \) is a set and \( \Gamma : \mathcal{M} \rightarrow \text{Gen}[S] \) is a faithful continuous functor. We also assume that \( \mathcal{M} \) meets the m-hypothesis, and that, for \( b \) a formal \( \mathcal{M} \)-subset, \( b \) is an \( \mathcal{M} \)-isomorphism if and only if \( \Gamma(b) \) is a \( \text{Gen}[S] \)-isomorphism. Then Theorem 24 applies to all lifts of \( \Gamma \).

In terms of the particular example, \( \mathcal{M} \) is the category whose objects were all \( C^\infty \)-manifolds but whose morphisms consisted only of diffuse
$C^\infty$-functions, formal $\mathcal{M}$-subsets are finite covering maps whose Jacobian is invertible at each point, $S = IR$, and $\Gamma$ is the forgetful functor. Let $M, N \in \mathcal{M}$, and let $(G, \sigma)$ and $(H, \tau)$ be group actions on $M$ and $N$, respectively, which are discrete in the categorical sense. Let $M_0$ be the canopy of Type Int($\{1\}$) such that $M_0[1] = M$, $M_0[1, 1]$ is the disjoint union of copies of $M$, indexed by $G$, and, for $g \in G$, the restrictions of $\rho_1$ and $\rho_2$ to the $g$-th copy of $M$ are $1_M$ and $\sigma(g)$, respectively. Let $N_0$ denote the analogous canopy for $N$ and $H$. Then, as members of $\mathcal{M}^+$, $M_0$ is the quotient $G \setminus M$ and $N_0$ is the quotient $H \setminus N$. Let $\Gamma^+$ denote the continuous extension of $\Gamma$ to $\mathcal{M}^+ \longrightarrow \text{Gen}[S]^+$. Before we continue with the abstract situation, let us look at a particular choice of manifolds and actions. Schwarz, in [13], illustrates surprising behavior with a morphism from $\{-1, 1\} \setminus IR^2 \longrightarrow \{-1, 1\} IR$. As noted in Subsection 3.2, the canonical action by $\{-1, 1\}$ on $IR$ is not discrete in our category. However, we get the same effect by taking his situation and forming products with $IR$. Also, we have to worry that our functions are diffuse, a concept which is not in Schwarz’s work. Below is the update of his example.

Let $M = IR^3$, $N = IR^2$, $H = G = \{-1, 1\}$, and characterize the two actions by 

$$-1 \cdot (x, y, z) = (-x, -y, z) \quad \text{and} \quad -1 \cdot (x, z) = (-x, z).$$

Let $f : (0, \infty) \longrightarrow IR$ be a $C^\infty$-function such that

- (56.a) $f$ is periodic of period 4,
- (56.b) $f'$ is negative on intervals $(1,2)$ and $(2,3)$, and is positive on $(3,4)$ and $(4,5),$
- (56.c) all derivatives of $f$ vanish at every even integer,
- (56.d) $f(2k) = 0$ for all $k \in IN$. Equivalently, $f$ is positive on $(4k, 4k+2)$ and negative on $(4k+2, 4k+4)$ for all $k \in IN \cup \{0\}$. For each $x \in (0, \infty)$, define $g(x) = e^{-n} f \left( \frac{1}{x} \right)$ where $n$ is the smallest even integer greater than or equal to $1/x$. Adopt the convention that $g(0) = 0$. Define $F : M \longrightarrow N$ by

$$F(r \cdot \cos(\theta), r \cdot \sin(\theta), z) = \begin{cases} 
(g(r) \cdot \sin(\theta), z) & \text{if } g(r) > 0 \\
(g(r) \cdot \sin(2\theta), z) & \text{if } g(r) \leq 0
\end{cases}$$

for all $(r, \theta, z) \in [0, \infty) \times [0, 2\pi] \times IR$. (57)

Standard theory verifies that $F$ is $C^\infty$. We must verify that $F$ is diffuse. On any subset where $F$ can be identified with a projection $U \times V \longrightarrow V$, $F$ is diffuse. Also, if $F$ is diffuse on each member of a family of open subsets, then it is diffuse on the union. Thus, restriction of $F$ to the set of points where its Jacobian is surjective is diffuse.

For each $x \in (0, \infty)$, define $g(x) = e^{-n} f \left( \frac{1}{x} \right)$ where $n$ is the smallest even integer greater than or equal to $1/x$. Adopt the convention that $g(0) = 0$. Define $F : M \longrightarrow N$ by

$$F(r \cdot \cos(\theta), r \cdot \sin(\theta), z) = \begin{cases} 
(g(r) \cdot \sin(\theta), z) & \text{if } g(r) > 0 \\
(g(r) \cdot \sin(2\theta), z) & \text{if } g(r) \leq 0
\end{cases}$$

for all $(r, \theta, z) \in [0, \infty) \times [0, 2\pi] \times IR$. (57)

Standard theory verifies that $F$ is $C^\infty$. We must verify that $F$ is diffuse. On any subset where $F$ can be identified with a projection $U \times V \longrightarrow V$, $F$ is diffuse. Also, if $F$ is diffuse on each member of a family of open subsets, then it is diffuse on the union. Thus, restriction of $F$ to the set of points where its Jacobian is surjective is diffuse.
In $M$, let $\ell$ be the line $\{(0,0)\} \times IR$. For each $n \in IN$, let $C_n$ be the cylinder of all points distance $1/(2n)$ from $\ell$. Let $C$ be the union of these cylinders with $\ell$. For each odd integer $k$, let $\Xi_k$ be the union of lines of points of the form $(1/k, a, z)$ where $a \in \{\pi/2, 3\pi/2\}$ or $a \in \{\pi/4, 3\pi/4, 5\pi/4, 7\pi/4\}$, depending on the sign of $g(1/k)$. Let $\Xi$ be the union of these sets of lines. A brief calculation verifies that $F$ is diffuse on $M$ minus $C \cup \Xi$. In fact, our characterization of $f$ allows us to rule out the cylinders. Although the Jacobian degenerates, one can make a continuous identification with projection. Instead, let us use this example as an excuse to introduce two practical lemmas.

**Proposition 24.** Let $X, Y \in \text{Gen}$ and let $f : X \rightarrow Y$ be a continuous function. Let $I \subseteq X$ be a negligible subset. If the restriction of $f$ to $X - I$ is diffuse, then $f$ is diffuse.

**Proof.** This is a trivial consequence of Corollary [1]. □

Being diffuse is a local property, so we may invoke Proposition 24 on each line in $\Xi$. Therefore, $F$ is diffuse on $M$ minus $C$. In fact, we can go further. The axis $\ell$ is negligible in $M$, so to prove that $F$ is diffuse on $M$, it suffices to prove the diffuse property on $M - \ell$. Consequently, it suffices to prove that $F$ is locally diffuse about each individual cylinder $C_n$.

**Proposition 25.** Let $X$ be a topological manifold, let $Y \in \text{Gen}$ be normal (and Hausdorff) in the topological sense, and let $f : X \rightarrow Y$ be a continuous function. Let $Z$ be a submanifold of $X$ of codimension 1. Suppose $f$ is diffuse on $X - Z$. Then $f$ is diffuse unless and only unless there is a non-empty open subset $W$ of $Z$ such that the closure of $f(W)$ is negligible in $Y$.

**Proof.** Suppose $f$ is not diffuse. Let $(U, I)$ be a negligible subset-element of $Y$ whose inverse is not negligible. Now $f^{-1}I - Z$ is known to be negligible in $f^{-1}U - Z$. Thus, $f^{-1}U \cap Z$ must not be negligible in $f^{-1}U$. There is $x \in Z \cap f^{-1}I$ at which the local condition of Lemma 3 fails. Because $Z$ is of codimension 1, it follows easily that there is a neighborhood $W_1$ of $x$ in $Z$ which is entirely contained in $f^{-1}I$. Now $Y$ is normal and Hausdorff, so there is a closed neighborhood $T$ of $f(x)$ in $Y$ such that $T \subseteq U$. Let $W_2 = W_1 \cap f^{-1}T$, and let $W$ be the interior of this set with respect to the topology of $Z$. Then $x \in W$ and the closure of $f(W)$ in $Y$ is a closed subset of $I$. It follows that $W$ has the stated properties. The converse is trivial. □
On each cylinder, $F$ is projection $(x, y, z) \mapsto (0, z)$. The closure of the image, under $F$, for any non-empty open subset of the cylinder will contain a line segment. In $N$, any line segment fails to be negligible. Hence, $F$ is diffuse.

We are ready to consider morphisms at three levels.

Let us recall how $M_0$ serves as $G \backslash M$. The quotient map is $\iota = \iota_1^*: M^+ \to M_0$. The map $\iota$ is purely formal. Its construction does not include a subtle study of quotients. What links the purely formal to the practical is the lift of the functor $\Gamma$.

Consider the situation when $M$ is a manifold. Let $q : \Gamma(M) \to Q$ be the standard topological quotient. (Here, $\Gamma(M)$ is just $M$ with differential structure omitted.) If the fixed point set of each non-trivial member of $G$ is negligible, then we know that $q$ describes a pseudoétaile quotient with respect to $\text{Gen}$. In other words, we may choose $\Gamma^+ (\iota)$ to be $q$ and $\Gamma^+ (M_0) = Q$. It is justified as, up to isomorphism, the only way to extend $\Gamma$ continuously.

Unfortunately, it is possible that $q$ is not pseudoétaile. This is the case if $M = \mathbb{IR}^2$ and $\{-1, 1\}$ acts as described earlier. In this case, $\Gamma^+ (M_0)$ cannot be assigned a $\text{Gen}$-object without violating continuity of functors. It is tempting to define it to be $Q$, but, as we shall show shortly, this decision would sacrifice the valuable property of faithfulness. We may say that $\Gamma^+ (M_0)$ exists in a suitable expansion $\text{Gen}[S]^+$ of $\text{Gen}[S]$, and, in that expansion, it serves as $G \backslash \Gamma(M)$. We may also say that the expansion supports a fundamental group and cohomological theories, although these differ from the classical.

Actually, for our present question, $M_0$ is not the troublesome quotient. In $\mathcal{M}^+$, $M_0$ is a true quotient for the action by $G$. A morphism on $M_0$ may be effectively defined as a $G$-invariant morphism on $M$! So, definition of a morphism $M_0 \to N_0$ is really a question of definition from $M \to N_0$.

Our study reduces to two challenges:

(58.a) describe a morphism $M \to H \backslash N$,
(58.b) determine when two such morphisms agree.

Issue (58.b) runs directly into Seifert Boundaries and faithfulness of $\Gamma$.

Formally, a morphism $M \to N_0$ is represented by a pair $(\theta, f)$ where

(59.a) $\theta$ is a cover of $M$ (in $\mathcal{M}$) indexed by some set $J$,
(59.b) for each $j \in J$, $f(j)$ is an $\mathcal{M}^p$-morphism $M \to N_0$,
and certain conditions are met. Actually, in this case, $f(j)$ may be interpreted simply as an $\mathcal{M}$-morphism $M \to N$, with the understanding that certain morphisms are regarded as equivalent.
Even in an explicit context, such as the category of manifolds, each map $\theta(j)$ is not limited to be just open embedding. The family $\theta$ covers in the topology of $\mathcal{M}$. That topology includes finite-to-one maps. There is a good heuristic reason for this. Intuitively, we wish to define a morphism $M \to N_0$, but our language only contains morphisms between “affine” objects like $M$ and $N$. A given $f : M \to N_0$ need not factor through the canonical projection $\alpha : N \to N_0$. In this case, we can not represent $f$ as $\alpha$ composed with something. Instead, we try to classify $f$ by its pullback along $\alpha$ to $\pi : M^* = M \times_{N_0} N \to N$. Although the domain of $\pi$ need not be affine, it has a cover by affines, and $\pi$ restricted to each of these is a morphism in the old sense. Thus, $f$ gets expressed as a family of maps into $N$ from objects which are, crudely, open subsets of a finite cover of $M$. (This characterization is spiritually right, but too simple formally.)

We do have some leeway. We may replace any member of $\theta$ by a refinement. In particular, we may choose the maps so that each has its image constrained to lie in some indicated basis. We may pass from $\theta$ to its restriction to a subset of $J$, provided that the restriction covers. We may assume that the domain of each $\theta(j)$ is connected.

If the topology is based on morphisms with non-trivial ramification, then such morphisms may appear in $\theta$. The derived pseudoétagle topology is intended to include all forms of singularity which do not prevent certain manipulations. In it, a cover may consist of complicated maps. On the other hand, the elementary finite-to-one topology is intended to be the simplest of topologies from which quotients may be generated. In it, every cover can be refined to a pseudogeometric cover; that is, in any concrete case, a usual cover by open subsets. In the standard theory of real orbifolds, if $M$ is a manifold (rather than an abstract orbifold) then $\theta$ may be chosen to be injections for all members of a cover by open subsets.

Two related questions arise.

(60.a) When does a pair $(\theta, f)$, represent an $\mathcal{M}^+$-morphism?

(60.b) Given pairs $(\theta, f)$ and $(\phi, g)$ which represent morphisms, when do they represent the same one?

In (60.a), it is necessary and sufficient that for every pair $(j, k) \in \text{dom}(\theta)^2$ and for any $(P; \pi_1, \pi_2)$ a product $\theta(j) \times_M \theta(k)$, it is true that $f(j) \circ \pi_1 = f(k) \circ \pi_2$. In (60.b), the key condition is that for every $j \in \text{dom}(\theta)$, $k \in \text{dom}(\phi)$ and any $(P; \pi_1, \pi_2)$ a product $\theta(j) \times_M \phi(k)$, it is true that $f(j) \circ \pi_1 = g(k) \circ \pi_2$. The basic issue is

(61) For each $U \in \mathcal{M}$ and $f, g : U \to N \mathcal{M}$-morphisms, when do $f$ and $g$ represent the same morphism into $N_0$?
The theory gives an unambiguous answer. However, there is an tempting deception.

The formalism is precise. Let $U$, $f$ and $g$ be as in (61). Then $f$ and $g$ represent the same thing if and only if there is an $\mathcal{M}$-morphism $\delta : U \to N_0[1, 1]$ such that

$$\rho_1 \circ \delta = f \quad \text{and} \quad \rho_2 \circ \delta = g.$$  \hspace{1cm} (62)

The first composition in (62) means that, on each connected component of $U$, $\delta$ restricts to a copy of $f$ which maps into one of the copies of $N$ in $N_0[1, 1]$. In other words, for each connected component $C$ of $U$, there is $h_C \in H$ such that

$$g(x) = h_C \cdot f(x) \quad \text{for all} \quad x \in C.$$  \hspace{1cm} (63)

The element $h_C$ depends solely on $C$.

There is another notion of equality that is attractive but flawed. Let $q : N \to H \setminus N$ be the topological quotient. It is tempting to identify the morphisms of $f$ and $g$ if $q \circ f = q \circ g$ in the topological sense. That is,

$$\text{(64) for each } x \in U, \text{ there is } h_x \in H \text{ for which } g(x) = h_x \cdot f(x).$$

Unlike (63), the member $h_x \in H$ depends on each point $x$. If $q : N \to H \setminus N$ is pseudo´ etale, then conditions (63) and (64) are equivalent. The link is that $N_0[1, 1]$ really is $q \times q$. Thus, $q \circ f = q \circ g$ implies existence of $\delta = f \times g$ which is the basis of (63).

Let us return to the explicit example of this Section. Put $f(v) = F(v)$ and $g(v) = F(-1 \cdot v)$. Then $F$ factors to a morphism $G \setminus M \to H \setminus N$ if and only if $f$ and $g$ determine the same morphism $M \to N_0$. Let $q : IR^2 \to \{-1, 1\} \setminus IR^2$ be the topological quotient. Certainly $q \circ f = q \circ g$ in Top. But, by inspection, $f$ and $g$ fail (63). In fact, $q$ is a false friend, and $F$ does not properly factor.

Equality should be a local property. Let $\mathcal{U}$ be a family of open subsets of $IR^3$. If, for each $V \in \mathcal{U}$, restrictions of $f$ and $g$ to $V$ are equal, then the restrictions of $f$ and $g$ to $U = \cup \mathcal{U}$ should agree. In fact, this is true. However, one must realize that $U$ excludes lots of points.

Let $x \in IR^3$. Suppose that for each neighborhood $V$ of $x$ there are $v, w \in V$ such that

$$F(v) = F(-1 \cdot v) \neq (-1) \cdot F(-1 \cdot v),$$

$$F(w) = (-1) \cdot F(-1 \cdot w) \neq F(-1 \cdot w).$$

Then restrictions of $f$ and $g$ to any neighborhood of $x$ will not agree. Obviously, every $x$ or the form $(0, 0, z)$ has this property; the function $F$ was tailored to be pathological near such points. Less obvious is the fact that each $x \in C_n$ has the same eccentricity. In fact, the
troublesome points divide $\mathbb{R}^3$ into disconnected chunks. Indeed, if they did not, the morphism $F$ would have factored.
