Background: Fungal infections affect various parts of the body and can be difficult to treat. Aspergillus infection causes a spectrum of diverse diseases particularly in lung according to host immunity. The two major entities are invasive pulmonary aspergillosis and chronic pulmonary aspergillosis. Candida infections can be superficial or invasive. Superficial infections often affect the skin or mucous membranes. However, invasive fungal infections are often life-threatening. Advances in nanotechnology have opened new horizons in nanomedicine, allowing the synthesis of nanoparticles that can be assembled into complex architectures. Novel studies and technologies are devoted to understanding the mechanisms of disease for the design of new drugs.

Objectives: In the present study, the antifungal activity of biogenic selenium nanoparticles (Se NPs) against Aspergillus fumigatus and Candida albicans was investigated.

Materials and Methods: Se-reducing bacteria previously identified as Bacillus sp. MSh-1 were used for the intracellular biosynthesis of elemental Se NPs. The shape, size, and purity of the extracted NPs were determined with various instrumental techniques. The nanoparticles antifungal characterization mainly derives from the following pathways: (i) to generate sustained flux of nano-ions from the compounds that deposited on special substrates or imbedded in colloidal or semisolid matrices. (ii) To transport active those ions to sensitive targets on plasma membrane of fungi.

Results: The results of energy-dispersive X-ray demonstrated that the purified NPs consisted of only Se. In addition, transmission electron micrographs showed that 120- to 140-nm spherical Se NPs were the most common. An antifungal assay was performed with a standard Clinical and Laboratory Standards Institute broth microdilution method. Minimum inhibitory concentration (MIC) measurements of the antifungal activity of the Se NPs against C. albicans (70 μg/mL) and A. fumigatus (100 μg/mL) showed that yeast cells were more sensitive than mold cells.

Conclusions: The MICs against A. fumigatus (100 μg/mL) and C. albicans (70 μg/mL) showed that biogenic Se NPs are useful antifungal agents.

Keywords: Selenium Nanoparticles; Antifungal Activity; Metal Nanoparticle; Antifungal Agent; Fumigatus; Aspergillus fumigates; Candida albicans

1. Background

Because pathogenic fungi have become resistant to current antifungal agents, the development of new antibiotics or novel antimicrobial formulations is essential. The antifungal capacities of various organic and inorganic materials against pathogenic fungi have been tested in recent decades and the development of such novel compounds is ongoing (1). Selenium (Se) is a micronutrient metalloid incorporated (in the form of selenomethionine or selenocysteine) in the structure of enzymes such as glutathione peroxidases, iodothyronine deiodinases, and thioredoxin reductase, which are involved in antioxidant defense, detoxification, and metabolism, respectively (2, 3). The low toxicity of Se nanoparticles (NPs) and properties such as antibacterial, antiviral, and antioxidant activities have attracted research attention (4, 5). Nanotechnology allows the fabrication of novel compounds (i.e., NPs or nanoconjugates) with novel biological properties (6-9). Physicochemical techniques (10, 11), biological methods, and the synthesis of nanostructures with bacterial and fungal strains as well as several plant extracts offer novel, clean, non-toxic, and eco-friendly methods for the production of Se NPs (12,13).

Although Se compounds such as selenium sulfide (SeS2) have long been used as antifungal agents (14), the antifungal activity of biogenic Se NPs against Aspergillus fumigatus and Candida albicans has not been investigated. In the present study, biogenic Se NPs were purified from the whole-cell lysate of Bacillus sp. MSh-1 and characterized. Then, the antifungal efficacy of these novel NPs against A. fumigatus and C. albicans was studied.
2. Objectives

The aim of this study was to synthesize Se NPs, test them against the yeast cells of *C. albicans* and mold cells of *A. fumigatus*, and compare their minimum inhibitory concentrations (MICs) to determine their sensitivities.

3. Materials and Methods

3.1. Chemicals

Selenium dioxide (SeO$_2$), nutrient broth, potato dextrose agar, Sabouraud’s dextrose agar medium, 1-octanol, sodium dodecyl sulfate, and Tris-base were purchased from Merck Chemicals (Darmstadt, Germany). All other chemicals and solvents were of analytical grade.

3.2. Preparation of Biogenic Se NPs

Se NPs were prepared by reducing Se$^{+4}$ ions with the *Bacillus* sp. MSh-1, which was previously identified with a 16S ribosomal DNA method (GenBank accession number: GU183144.1) (13). Briefly, sterile nutrient broth was supplemented with SeO$_2$ (1.26 mM) and inoculated with an overnight colony of *Bacillus* sp. MSh-1 in a shaker incubator (30°C, 150 rpm) for 14 hours. Subsequently, cells containing elemental Se were isolated from the medium via centrifugation (4000 × $g$, 10 min). Cells were disrupted by using a mortar and pestle after washing with sterile normal saline and freezing with liquid nitrogen. One milliliter of disrupted cells containing Se NPs was dispersed in 2 mL 1-octanol, and the resulting two-phase system was centrifuged (5000 × $g$, 10 min). The biogenic Se NPs were settled and washed with chloroform, ethyl alcohol, and distilled water (13).

3.3. Characterization of Se NPs

After the Se NPs were sonicated (100 W, 5 minutes), transmission electron microscopy (TEM) images were recorded with a (Zeiss Supra 55 VP, Jena, Germany) equipped with an energy-dispersive X-ray (EDX) microanalyzer at an accelerating voltage of 100 kV. The size distribution pattern of the Se NPs was plotted by manually counting 400 individual particles from various TEM images.

3.4. Antifungal Activity

The antifungal activities of the Se NPs against *A. fumigatus* and *C. albicans* are shown in Table 1. The measured MICs for *A. fumigatus* (100 μg/mL) and *C. albicans* (70 μg/mL) showed that the biogenic Se NPs had good anti-fungal activity.

4. Results

Se NPs were successfully synthesized with *Bacillus* sp. MSh-1 as evidenced by a significant change in the cultivation medium from colorless to insoluble orange-red, indicating the presence of elemental Se (Se$^{0}$), after 14 hours (Figure 1). The TEM images of the Se NPs (Figure 2) showed that these well-dispersed spherical nanostructures had diameters ranging from 80 to 220 nm. The EDX pattern of the biogenic NPs had a strong SeL$\alpha$ peak at 1.37 KeV (Figure 3). Further more, SeK$\alpha$ and SeK$\beta$ peaks were observed at 1.37 and 11.22 KeV, respectively (see Figure 3). Subsequently, no signals for other elements were observed in the EDX pattern, which showed only the presence of the aforementioned signals for Se atoms (with the weight percent equal to 100).

The size distribution pattern revealed that 120- to 140-nm NPs were the most common particles (Figure 4). The antifungal activities of the Se NPs against *A. fumigatus* and *C. albicans* are shown in Table 1. The measured MICs for *A. fumigatus* (100 μg/mL) and *C. albicans* (70 μg/mL) showed that the biogenic Se NPs had good anti-fungal activity.

Table 1. Antifungal Activities of Biogenic Selenium Nanoparticles (Se NPs) against Aspergillus fumigatus and Candida albicans

| Fungal Strain         | Antifungal Activity of Se NPs MIC | Active Antifungal Drug MIC |
|-----------------------|----------------------------------|-----------------------------|
| *Aspergillus fumigatus* | 100                              | Amphotericin B 1             |
| *Candida albicans*    | 70                               | Nystatin 0.05               |

* MIC, minimum inhibitory concentration.

5. Discussion

Because nystatin resistance in *Candida* sp. has been reported, especially in immunocompromised patients, and amphotericin B is still widely used as a first-line drug for the treatment of invasive aspergillosis despite its low efficacy, the development of new agents that can be used against fungi is critical. Ramamurthy et al. used fenugreek seed extract for the biosynthesis of Se NPs (50 - 150 nm) after 72 hour incubation (17). In another study, supplementation of the culture supernatant of *A. terreus* with SeO$_2$ (100 μg/mL) produced Se NPs with an average size of 47 nm (18, 19). *Bacillus megaterium* (a halophile strain) strongly reduced selenite (up to 0.25 mM) to Se NPs after 40 hours of incubation (17). Our results showed that the *Bacillus sp. MSh-1* synthesized Se NPs (80 - 220 nm) after 14 hours of incubation.

The resistances of *Candida* sp. to nystatin has been reported, especially in immunocompromised patients (20). Amphotericin B is still widely used as first-line drug for treatment of invasive aspergillosis despite its lower efficacy (21, 22). Despite the development of new antifungal drugs, the number and variety of effective treatments remain limited (23). Therefore, use of NPs against pathogenic fungi is yet another novel approach. Se NPs have a variety of biological properties and might be candidates for a range of applications (24-26). Kazempour et al. (27) reported that the MICs of Se NPs (90 - 320 nm) biosynthesized with a two-phase system by using *Klebsiella pneumoniae* and without purification against *A. niger* and *C. albicans* were 250 µg/mL and 2000 µg/mL, respectively. The results of another study of biogenic Se NPs (100 - 600 nm) showed the highest antifungal activity against *Malassezia sympodialis* (MIC 10 µg/mL) and *M. furfur* (MIC 50 µg/mL) (28). Furthermore, the measured MICs of nanoseelenium against *A. niger, A. terreus, A. flavus, A. fumigatus* were 260 µg/mL, 60 µg/mL, 220 µg/mL, and 100 µg/mL, respectively, against AmB (28). Although our Se NPs (80 - 220 nm) were smaller than the Se NPs (100 - 600 nm) prepared by using *K. pneumoniae*, they showed the same levels of antifungal activity against *A. fumigatus*.

The results of the present study suggest that nanoscale biogenic elemental Se has antifungal activity against *A. fumigatus* and *C. albicans*. The mechanism of this antifungal effect is unknown and merits further in vivo and in vitro studies.
