ABSTRACT

Smilax wightii A.DC is an endemic medicinal plant belongs to the family smilacaceae and distributed in Kodanadu, The Nilgiri Hills, The Western Ghats, Southern India. The callus was obtained at the concentration of 1.5+0.05 mg/I TDZ with NAA. Highest number of shoots was observed in 2.0+0.04 mg/l BAP + Kn and followed by 2.0+0.04mg/l. The multiplied shoots were harvested and used for rooting on half strength MS medium containing indole-3-butyric acid and naphthalene acetic acid within 45 days. The best rooting response was achieved on half-strength MS medium supplemented with 2.0 mg/l IBA. The well rooted plantlets were acclimatized and successfully transferred to natural condition, where 85% plantlets were survived.

Key words: Callus, endemic medicinal plant, Smilax wightii.

1. INTRODUCTION

Plant tissue culture is the technique of growing plant cells, tissues and organs in an artificially prepared nutrient medium static or liquid, under aseptic conditions. Tissue culture is used for conservation of biological diversity by multiplication of plant species that have extremely small populations, for species with restricted reproductive capabilities and for recovery and reintroduction (Bramwell, 1990). The main areas of research in plant tissue culture viz. micropropagation, anther and microspore culture, somaclonal variations and mutagenesis, protoplast culture and somatic hybridization are some of the effective tools for regeneration and conservation of endangered plants (Bapat et al., 2008).

Smilacaceae comprises of 10 genera with more than 300 species, found on temperature zones, tropic and subtropics worldwide (Fnaec, 2002). Smilax wightii A.DC. is a rare endemic generally distributed in Shola forests at high altitudes in Nilgiri Biosphere Reserve, the Western Ghats, Southern India. The roots of S. wightii have been reported to cure dysentery, amoebiasis, veneral diseases, leucorrhoea, urinary complaints, fever, spermatorrhoea, antifertility, anaemia, rheumatic arthritis, veterinary amoebiasis and gastric complaints (Adhikari et al., 2010).

2. MATERIALS AND METHODS

2.1. Collection of plant material

The whole plant Smilax wightii was collected from Kodanadu, The Nilgiri Hills, The Western Ghats, Southern India, Tamil Nadu. The plant was identified and authenticated by a plant taxonomist, Coimbatore.

2.2. In vitro study

2.2.1. Explant sources

The fresh leaf samples of S. wightii was collected from its original habitat, and maintained in green house condition and one year old young, healthy, disease free leaves were used as explants, sources.

2.2.2. Explant sterilization

Freshly excised leaf explants of S. wightii was surface sterilized and washed in tap water for 2-5 minutes, and again rewashed with liquid detergent (Rankleen, Ranbaxy India) and Tween 20 (Himedia Laboratories, India) for 2-5 minutes with vigorous shaking. These explants were again washed with running tap water to remove any traces of detergent and kept in 1% (w/v) solution of Bavistin (BASP India Limited) for one hour and transferred to 1% (v/v) Savlon (Johnson and Johnson, USA) for 1-2 minutes. In the laminar hood there washed again 2-3 times with sterile distilled water. All these explants were taken and dipped in 70% ethyl alcohol for 30 seconds, surface sterilized with freshly prepared 0.1% (w/v) aqueous solution of mercuric chloride for 20-30 seconds and thoroughly washed with 3-4 times with sterile water and removed all traces of mercuric chloride.

2.2.3. Culture media

The basal medium used for the culture is Murashige and Skoog medium with sucrose 3% (Analytical grade, Himedia, India) and 0.8% agar (Bacteriological grade, Himedia, India) was used the
composition of this medium consist of growth hormones, 6 -benzylamino purine (BA), Thiadiazuron (TDZ), 3 -indole butyric acid (IBA), Kinetin (Kn), adenine sulphate were added to the basal medium either singly or in various combinations. Cytokinins were dissolved first with the respective acidic solution (1N Nhcl) and auxins in few drops of basic solutions (1NKOH). The final volume was made up with distilled water and kept in refrigeration. (Growth regulators are from Sigma, USA). Generally, after adding all the ingredients in required amounts, the final volume was made up with distilled water. The pH of the medium was adjusted to 5.8 by using 1NKOH or 1NHcl (Cyber scan 510, Eutech Instruments, Singapore), agar (Himedia Labs Limited, India) added to the medium at the rate of 0.8% (w/v) for solidification of the medium, The media (50 ml/300 ml bottle) were transferred in to the bottles which were tightly capped and labelled properly in to the media was autoclaved (Equitron, Medical Instuments, India) at 121°C for 20 minutes at 15 psi.

2.2.4. Inoculation of the explants

All the explants were sterilized, trimmed and inoculated in culture bottles aseptically and transferred to culture tubes with the help of sterile forceps under strict aseptic conditions. The mouths of the tubes were quickly flamed and culture tubes tightly capped and the mouth of the tubes were properly sealed with cotton plug to avoid entry of external air. All the tubes were properly labelled and transferred to aseptic culture room.

2.2.5. Culture conditions

All cultures were incubated and maintained under 16 hours photoperiod with light intensity of 2000-2500 luX (Polylux XL, GE Britain, 36 W and temperature of 25±10°C).

3. RESULTS

An In vitro propogation method has been developed for S. wightii, an endemic medicinal plant from Kodanadu, the Nilgiri Hills. In the present study, the leaf explants of S. wightii were excised from their natural habitat and maintained in green house were cultured on MS basal medium supplemented with various concentrations of BA, TDZ and 2,4-D and combinations of NAA with BA, NAA with 2,4-D and NAA with 2,4-D at various concentrations for the induction of callus.

3.1. Callus proliferation

The leaf explants were cultured on MS basal medium supplemented with BA, 2-4D and TDZ with regulators separately in different concentrations (0.1, 0.5, 1.5 and 2.0 mg/L) and NAA with a concentration of 0.05 mg/L was combined with BA, 2,4-D and TDZ at different concentrations (0.1,0.5,1.5 and 2.0 mg/L). In the above combinations callus formation from leaf explants were achieved by using MS medium supplemented with BA (2.0 mg/L), TDZ with (2.0 mg/L), NAA with BA (0.05 + 2.0), NAA with 2,4-D (0.05 + 2.0) and NAA with TDZ (0.05 + 2.0) respectively (Table-1).

The callus formation was observed on MS basal medium with TDZ in the concentration of 2.0 mg/L with respect to 73% in leaf explants. MS medium with TDZ + NAA combinations (1.5+0.05 mg/L) showed 83% callus formation. BA and NAA in the concentration of 1.5+0.05 (mg/L) developed 74% callus formation. Among these concentrations of growth regulators, maximum callus formation for leaf explant was observed on MS basal medium with TDZ+NAA (1.5+0.05 mg/mL) (Table-2). It was observed that leaf explants cultured in the basal medium containing 2,4-D appeared to be white green coloured and friable callus. The BA, BA in combination with NAA, and TDZ, TDZ in combination with NAA developed light green coloured and compact callus. Crystallized callus mass which turned to hard, compact green solid mass of callus growth within 20-27 days (Table-2).

4. DISCUSSION

Plant tissue culture techniques enable high efficiency and quick production of ethic and pathogens-free plants besides provoke a considerable interest as a potential alternative to produce bioactive compounds. Plant growth regulators are fundamental to integrate and regulate plant development and their addition in culture media have been widely employed to improve morphogenesis and plant development. In vitro propagation techniques offer an option for the conservation of rare, threatened and endangered medicinal plants (Mallon et al., 2010). These techniques used for rapid and large-scale propagation of medicinal, aromatic, crop, ornamental plants and for the isolation and enhancement of more medicinal secondary products (Sahoo et al., 1997). Plant tissue culture production of medicinal plants offers a number of unique advantages like possibility of year-round continuous production of phytochemicals under controlled conditions (Kayser and Quax, 2007).

The present study is described the in vitro regeneration of an endemic medicinal plant, Smilax wightii of Smilacaceae from the leaf explants. These explants were cultured on MS basal medium supplemented with various concentrations of, BA
TDZ, 2,4-D and with combinations of NAA, for the induction of callus and subsequent development of plantlets. MS medium has showed the highest percentage and dry weight of the callus in *S. wightii*. Khatun *et al.* (2003) have reported that MS was the most suitable media for callus induction. *S. tetrandra* grown on different basal salt media developed maximum callogenesis with one fold MS media. Addition of peptone into MS the culture medium has strongly improved the growth of tobacco callus. In the study, the addition of peptone (2g/L) has promoted callus growth. Because peptides could be more efficient source of nitrogen for sustaining in vitro callus proliferation. The texture of callus varied according to the nature of cytokinin and also on auxin and cytokinin ratio (Martin, 2002). Morphological and phytochemical differences in callus are attributing to culture conditions, composition of the medium orientation of the explants, and growth and morphogenesis ability of plants itself. Various types and concentration of hormones present in medium directly affect the nature, colour and biochemical composition of callus (Skoog and Miller, 1967).

It may be explained that the specific growth hormones at appropriate concentrations can play major role to induce callus besides the other factors (Ananthi *et al.*, 2011). Baskar and Jayabalan (2005) suggested that the differential response of same or different explants for callus formation could be due to the nature of tissue, degree of totipotency and composition of medium with respect to micronutrients and hormones. Further, it is explained that the variation in response of leaf discs in terms of callus formation may be due to the variation in distribution of endogenous level of growth regulators as observed in plants (Farternale *et al.*, 2002). The present results of *S. wightii* leaf explants indicated that individual growth regulators are not developed any organs or callus induction. However, several combinations of growth regulators have shown to induce the formation of callus. The young moderate sized leaf explants were well responded for rapid callogenesis after incubation period of 4 weeks. A pale green colour and healthy compact calli were observed on first week of inoculation at the trimmed regions on MS media supplemented with 1.5 mg/L TDZ concentrations. The highest callus fresh weight was obtained in the medium containing 1.5mg/L TDZ + 0.02mg/L NAA combinations.

Variations in the callus forming ability of different explant types have reported in many plants. Callus from leaf segments showed initiation of vigorous, proliferating, soft and green colored tissue (Chand and Roy, 1980). TDZ, a synthetic phenylurea is considered to be one of the most active cytokinins for callus and shoot induction in plant tissue culture. TDZ-induced callus induction from different explants of many recalcitrant species as well as from medicinal plants has been reported. Several reports suggest that TDZ results in callus induction better than other cytokinins.

Aditi Singh *et al.* (2009) have explained callus formation in *Tinospora cordifolia* developed from nodal, inter-nodal and leaf explants when planted on the MS medium containing the combination of BAP and NAA. Of these, callusing response was seen only on leaf explants study have showed a combination of 2,4-D, BAP and Kin (2.0, 2.0 and 2.0 μM) in MS medium enhances the callus production in *Coscinium fenestratum*. Our results are similar to Kuo *et al.* (2005) investigations, where an efficient in vitro callus induction system in *S. Wightii* was established on MS medium supplemented with 3% sucrose and different concentrations of plant growth regulators i.e. auxins (2,4-D, IAA and NAA) and cytokinins (BA, kinetin, TDZ and zeatin) in the dark. MS medium supplemented with 1.0mg/L BA and 0.5 mg/L TDZ supported callus growth and its proliferation. A maximum amount of dry biomass (7.8 fold) was produced 45 days after culture. Similarly in *Taxus wallichiana* the stem explants developed brown friable callus in different basal media, supplemented with 2mg/L of 2,4-D. Callus induction was found to be best in MS media solidified with 10g/L agar and supplemented with 1-5mg/L BA. Further, addition of kinetin (1-5mg/L) has resulted in more active callus formation. The colour of calluses ranged from brown to green, greenish yellow and yellow.

Callus potential has reported to vary from species to species and often differs in varieties of same species (Pradeep Kumar and RanjithaKumari, 2010). Karappusamy and Pullaiah (2007) have reported an effective callus formation from the leaf explant in the medium containing high quantity of NAA for *Bupleurum distichophyllum*. Mariani *et al.* (2011) have suggested the requirement of the cytokinin like compounds, TDZ for callus formation in *Aglaonema spp*. The cytokinin is known major growth hormone involved in shoot formation of plant species (Sujatha *et al.*, 2008).

The highest number of shoots from leaf explants of *S. wightii* were observed in TDZ+NAA (1.5+0.03 and 2.0+0.04mg/l) and followed by 2.0+0.04mg/l of BA+NAA combinations when the callus cultured in MS medium. The regeneration frequency was high in TDZ and BA combined with NAA. These results were similar to Kannan *et al.*
(2007) who have established an in vitro propagation of *Excaum travancoricum*. The internodal explant of *E. travancoricum* was cultured on MS with different levels of Thidiazuron or BA showed gradual bulging. They have observed the direct shoot morphogenesis on the cut ends of the explants cultured on MS medium with TDZ or BA. Here, TDZ was superior to BA in the induction and proliferation of shoots. The shoots induced on TDZ enriched medium were healthier than the shoots raised on BAP. Culture of shoot clumps on MS medium having TDZ favoured proliferation of shoots. The high efficient of TDZ over BA has been documented in several woody plants (Vidya *et al.*, 2005).

### Table 1. Effect of different concentrations of plant growth regulators on callus induction from leaf explants of *Smilax wightii*.

| Plant growth regulators | Concentration of plant growth regulators mg/L | Intensity of callus formation | Leaf explant | Mean callus weight ± SD | Nature of callus |
|-------------------------|---------------------------------------------|--------------------------------|--------------|-------------------------|-----------------|
| Control                 | --                                         | --                            | --           | --                      | No callus formed |
| BA                      | 0.1 +                                      | 0.32 ± 0.03                  | White green friable |
|                         | 0.5 +                                      | 0.45 ± 0.17                  | White green friable |
|                         | 2.0 ++                                     | 0.74 ± 0.26                  | Light green, compact |
|                         | 0.1 ++                                     | 0.33 ± 0.12                  | White green friable |
| TDZ                     | 1.5 +                                      | 0.49 ± 0.23                  | White green, friable |
|                         | 2.0 ++                                     | 0.68 ± 0.06                  | Light green, friable |
|                         | 0.1 +                                      | 0.85 ± 0.34                  | Light green, compact |
| 2,4-D                   | --                                         | --                            | 25 ± 0.11     | White green, friable |
|                         | 2.0 ++                                     | 0.32 ± 0.23                  | White green, friable |
|                         | 0.5+0.05                                  | 0.38 ± 0.04                  | White green, friable |
| RA + NAA                | 1.5+0.05                                  | 0.34 ± 0.16                  | White green, friable |
|                         | 2.0+0.05                                  | 0.51 ± 0.32                  | White green, friable |
|                         | 0.5+0.05                                  | 0.87 ± 0.26                  | Light green, compact |
| 2,4-D + NAA             | --                                         | --                            | 0.27 ± 0.41   | White green, friable |
|                         | 1.5+0.05                                  | 0.39 ± 0.17                  | White green, friable |
|                         | 2.0+0.05                                  | 0.42 ± 0.08                  | White green, friable |
|                         | 0.1+0.05                                  | 0.76 ± 0.12                  | White green, friable |
| TDZ + NAA               | 1.5+0.05                                  | 0.84 ± 0.23                  | White green, friable |
|                         | 2.0+0.05                                  | 0.92 ± 0.08                  | Light green, compact |
|                         | ++                                        | 1.42 ± 0.22                  | Light green, compact |

Intensity of callus: (+) low; (++) moderate; (+++) high.

Values are expressed as Mean ± Standard Error of 3 replicates. Means within a column followed by a common letter aren’t significantly different at 5% level by SPSS.

### Table 2: Effect of different concentrations of plant growth regulators on the duration and percentage of callus formation from leaf explants of *Smilax wightii*.

| Plant growth regulators | Concentration of plant growth regulators mg/L | Days required for callus formation after inoculation | Callus formation (%) |
|-------------------------|---------------------------------------------|----------------------------------------------------|----------------------|
| BA                      | 0.1                                         | 0                                                  | 0                    |
|                         | 0.5                                         | 27 ± 0.02                                          | 50 ± 0.02            |
|                         | 1.5                                         | 25 ± 0.05                                          | 65 ± 0.12            |
|                         | 2.0                                         | 23 ± 0.04                                          | 53 ± 0.01            |
| TDZ                     | 0.1                                         | 24 ± 0.02                                          | 61 ± 0.08            |
|                         | 0.5                                         | 23 ± 0.01                                          | 66 ± 0.02            |
|                         | 1.5                                         | 24 ± 0.02                                          | 71 ± 0.14            |
|                         | 2.0                                         | 22 ± 0.13                                          | 73 ± 0.04            |
| 2,4-D                   | 0.1                                         | 0                                                  | 0                    |
|                         | 0.5                                         | 26 ± 0.06                                          | 43 ± 0.05            |
|                         | 1.5                                         | 25 ± 0.11                                          | 40 ± 0.02            |

100
Values are expressed as Mean ± Standard Error of 3 replicates. Means within a column followed by a common letter aren’t significantly different at 5% level by SPSS.
