Abstract: Phenolic antioxidants are used in the industry to delay the oxidation of fats, with the most used being butyl hydroxy anisole (BHA) and butyl hydroxy toluene (BHT). However, the consumer concern regarding their safety has motivated the study of natural alternatives. In this sense, the aim of this work was to evaluate the behavior of 3,3′-dimethoxy-5,5′-di-2-propenyl-1,1′-biphenyl-2,2′-diol and 6,6′-dihidroxi-5,5′-dimethoxy-(1,1′-biphenyl)-3,3′-dicarbaldehyde free and supported on mesoporous alumina. Biphenolic compounds were synthesized by radical coupling and then anchored on alumina by microwave assisted process. The antioxidant activity of these compounds was investigated by phosphomolybdenum method. The results showed that biphenolic compounds anchored on mesoporous alumina have a marked antioxidant activity, better than free antioxidants. Biphenolic compounds supported on alumina display antioxidant properties allowing a new opportunity for the developing in food and cosmetics packaging.

Keywords: antioxidant activity; phosphomolybdenum method; biphenolic compounds

1. Introduction

Additives are substances which are added on foods with a technological objective or to provide a functional property. In this sense, antioxidants are added to foods to minimize rancidity, retard the formation of toxic oxidation products, maintain nutritional quality, and increase shelf life [1].

It is known that methoxyphenols are antioxidant. They owe their activity to the ability to trap the chain-carrying peroxy radicals (ROO•) by donation of the phenolic hydrogen atom reaction (Equations (1)), which is a very much faster reaction than the attack of the peroxy radicals on the organic substrate (RH) [2].

\[
\begin{align*}
\text{ROO}^• + \text{ArOH} & \rightarrow \text{ROOH} + \text{ArO}^• \\
\text{ROO}^• + \text{RH} & \rightarrow \text{ROOH} + \text{R}^• \\
2 \text{ROO}^• & \rightarrow \text{non radical products}
\end{align*}
\]

Phenolic compounds could react with free radicals such as ROO, RO, OH and O•− much faster than the phospholipid that is always present at much higher quantities in living cells than the antioxidant [2]. Nowadays the industry uses synthetic antioxidants. However, natural products are increasingly in demand for consumers. In this sense, the aim of this work was to evaluate the behavior
of two biphenyl compounds, 3,3'‐dimethoxy‐5,5'‐di‐2‐propenyl‐1,1'‐biphenyl‐2,2'‐diol (BiEG) and 6,6'‐dihidroxi‐5,5'‐dimethoxy‐(1,1'‐biphenyl)‐3,3'‐dicarbaldehyde (BiVA) free and supported on mesoporous alumina (MA).

Mesoporous alumina was chosen because it has suitable structure, large specific surface area and high pore volume, enabling high loading of active species [3]. Its stability leads to better dispersion, biocompatibility, and subsequent functionalization [4].

2. Materials and Methods

2.1. Synthesis of Biphenolic Compounds

The synthesis of biphenolic compounds was realized by radical coupling following [5,6]. Mesoporous alumina was synthesized in accordance with the published procedure [7] using Pluronic P123 as template. In a typical experiment, the triblock copolymer Pluronic P123 (3 g) and aluminum trichloride (0.4 g) were dissolved in 60 mL of ethanol under stirring at 40 °C. Then, aluminum isopropanoxide (6 g) was added to the solution. The solution was maintained at 40 °C for 2 h, and the surfactant was removed by calcination, which was carried out by increasing the temperature to 400 °C for 4 h. The supporting of phenolic compounds on mesoporous alumina were performed by a microwave assisted oven procedure [8].

2.2. Characterization of Biphenolic Compounds

Biphenolic compounds (BiEG and BiVA) were checked by melting points and spectroscopic studies (IR, 1H-NMR, 13C-NMR). The equipment used to determinate FTIR was a Shimadzu FTIR Prestige-21 spectrophotometer, and magnetic resonance nuclear tests were made on a Bruker DPX-300 (300 MHz) spectrometer.

2.3. Determination of Antioxidant Activity

The assay was carried out by phosphomolybdenum method which is based on the reduction of Mo(VI) to Mo(V) by the sample and the formation of a green complex. Decrease of absorbance is directly proportional of antioxidant activity of sample [9]. Briefly, the method consisted of preparing solutions of biphenolic compounds in ethanol. Then 1 mL of sample solution was mixed with 9 mL of reactive solution and incubate at 95 °C for 120 min. The absorbance was measure at 695 nm against a blank on a Perkin Elmer Lambda 20 spectrophotometer. Results obtained were compared with butyl hydroxy toluene (BHT). Antioxidant activity was expressed as inhibition (I) calculated by the equation where As is initial absorbance, As120 is the absorbance of the sample at 120 min, Ac is initial absorbance of control, and Ac120 is the absorbance of control at 120 min (Equation (2)).

\[
I (\%) = \frac{1 - (A_s - A_{s120})}{(A_c - A_{c120})}
\]

2.4. Characterization of Materials

Materials free and with biphenolic compounds anchored were characterized by nitrogen adsorption/desorption isotherms. The measurements were performed with a NOVA-1000 Quantachrome at liquid nitrogen temperature (77 K). The specific surface areas of the samples were calculated using the Brunauer–Emmett–Teller (BET) method in the relative pressure range of 0.05–0.35. The pore size distribution (PSD) curves were derived from the adsorption branches of the isotherms using the Barrett–Joyner–Halenda (BJH) method. The pore volumes were obtained from the adsorption branches of the isotherms at a partial pressure of 0.99. Small angle X-ray scattering patterns (SAXS) were realized with a XEUS1 1.0, with Cu K radiation of wavelength 1.54178 Å.

3. Results and Discussion

Results obtained by FTIR, melting points and NMR confirmed the structures and purity of the compounds.
N\textsubscript{2} adsorption/desorption isotherms of materials are shown in Table 1. BiVA and BiEG anchored on mesoporous alumina caused a reduction on BET surface, pore volume and average pore diameter, which is attributed to the biphenolic compounds found inside the pores of the alumina, reducing the adsorption of nitrogen and consequently the textural parameters of alumina free.

| Sample     | Specific Surface Area (m\textsuperscript{2}/g) | Pore Volume (cm\textsuperscript{3}/g) | Average Pore Diameter (Å) |
|------------|-----------------------------------------------|--------------------------------------|---------------------------|
| MA         | 266                                           | 0.90                                 | 136                       |
| BiVA-MA    | 180                                           | 0.10                                 | 22                        |
| BiEG-MA    | 157                                           | 0.54                                 | 158                       |

The small angle patterns indicate the presence of a wormlike channel type [7]. For the sample with BiEG and BiVA, the presence of these compounds on MA rises to a decrease in the diffracted intensity (Figure 1).

To evaluate the antioxidant activity of synthetized materials the phosphomolybdenum method was used. The Mesoporous alumina (MA) did not show antioxidant activity. BiVA and BiEG presented antioxidant properties. Biphenolic compounds anchored on mesoporous alumina presented higher antioxidant activity than those free compounds (Figure 2).
4. Conclusions

In summary, biphenolic compounds were synthesized and then anchored on mesoporous alumina through a microwave assisted process. The physicochemical characterization of these materials confirmed the successful anchoring of the compounds into the mesoporous alumina. These systems show higher antioxidant properties when they are anchored on mesoporous alumina, allowing a new opportunity for the developing in food and cosmetics packaging.
