CF$_3$SO$_2$X (X = Na, Cl) as reagents for trifluoromethylation, trifluoromethylsulfenyl-, -sulfinyl- and -sulfonylation. Part 1: Use of CF$_3$SO$_2$Na

Hélène Guyon, Hélène Chachignon and Dominique Cahard*

Abstract
Sodium trifluoromethanesulfinate, CF$_3$SO$_2$Na, and trifluoromethanesulfonyl chloride, CF$_3$SO$_2$Cl, are two popular reagents that are widely used for the direct trifluoromethylation of a large range of substrates. Further, these two reagents are employed for the direct trifluoromethylsulfonylation and trifluoromethylsulfinylation, the introduction of the SCF$_3$ and the S(O)CF$_3$ group, respectively. In addition to the aforementioned reactions, the versatility of these two reagents is presented in other reactions such as sulfonylation and chlorination. This first part is dedicated to sodium trifluoromethanesulfinate.

Introduction
In organofluorine chemistry, the CF$_3$ group occupies a place of choice as privileged structural motif in the development of multifaceted catalysts and ligands for organic synthesis as well as in the design of pharmaceuticals, agrochemicals and specialty materials [1-4]. The trifluoromethyl group is most of the time linked to a carbon atom but can also be encountered with chalcogens (S, Se, O) and nitrogen. The CF$_3$S motif, which was till recently considered as an emerging substituent, is henceforth a tamed substituent as a result of abundant literature describing methods to prepare CF$_3$S-featuring molecules [5]. Its oxidised congeners CF$_3$S(O) and CF$_3$SO$_2$ are also well-developed as structural units in biologically active compounds, catalysts for synthesis, and functional materials. The chemistry of CF$_3$Se derivatives is less developed but basically shares the same synthetic approaches with CF$_3$S analogues [6,7]. The CF$_3$O group is also of high interest but difficulties still exist to easily introduce this motif directly onto organic molecules [8]. The reasons behind such massive interest for the CF$_3$ group are due to the specific physical and chemical properties of the compounds that contain it. The CF$_3$ group has a large van der Waals volume somewhere between those of the iPr and the t-Bu groups [9]. Its electronegativity is comparable to that of oxygen.
nitrile, methanol and acetone [13]. Although this reagent was solid (mp 350 °C) soluble in water and slightly soluble in acetonitrile, trifluoromethane sulfonic acid sodium salt, Langlois Sodium trifluoromethanesulfinate (alternate names: sodium trifluoromethanesulfinate, trifluoromethanesulfinic acid sodium salt, Langlois). A special emphasis is placed on mechanistic studies. The review is divided in Part 1 and Part 2 that are published back-to-back. The literature is comprehensively covered through July 2017. Traditional radical CF3 sources include the gaseous trifluoriodomethane CF3I and trifluorobromomethane CF3Br. More conveniently, the liquid trifluoromethanesulfonyl chloride CF3SO2Cl and the solid sodium trifluoromethanesulfinate CF3SO2Na that are commercially available at reasonable prices, are easy-to-handle sources of trifluoromethyl radicals. Remarkably, CF3SO2Na and CF3SO2Cl are multi-purpose reagents since they not only act as CF3 donors by extrusion of SO2, but also, under certain reaction conditions, the sulfur atom is retained for trifluoromethylsulfenylation (also named trifluoromethylthiolation), trifluoromethylsulfinylation, or trifluoromethylsulfonylation reactions. Typically, CF3SO2Na reacts under oxidative conditions whereas CF3SO2Cl requires reductive conditions. The advent of a new dynamism and the versatility of these two reagents have been recently demonstrated through several creative research articles; hence, this review aims to collect the recent progresses in the diverse uses of CF3SO2Na and CF3SO2Cl reagents. A special emphasis is placed on mechanistic studies. The review is divided in Part 1 and Part 2 that are published back-to-back. The literature is comprehensively covered through July 2017.

Review

Sodium trifluoromethanesulfinate (alternate names: sodium triflate, trifluoromethanesulfinic acid sodium salt, Langlois reagent), CAS No. 2926-29-6, MW 156.06, is a stable white solid (mp 350 °C) soluble in water and slightly soluble in acetonitrile, methanol and acetone [13]. Although this reagent was prepared in 1955 by Haszeldine [14] and in 1976 by Roesky [15], it is only in 1991 that Langlois reported the trifluoromethylation of aromatic compounds under oxidative conditions [16]. Since then, the use of CF3SO2Na has grown considerably for the creation of Csp3-CF3, Csp2-CF3 and Csp-CF3 bonds [17–19]. This reagent is also conveniently used in trifluoromethylsulfenylation and trifluoromethylsulfonylation reactions. More recently, from 2015, CF3SO2Na has found a new application as source of SCF2 for direct trifluoromethylsulfonylation.

1 Trifluoromethylation

Csp3-CF3 bond-forming reactions

**Synthesis of α-trifluoromethyl ketones from alkenes:** After their original reports on the trifluoromethylation of aromatics (see later in the text, Scheme 34) [16] and disulfides (Scheme 69) [20], Langlois and co-workers demonstrated that enol acetates 1a–c were converted into the corresponding α-trifluoromethyl ketones upon treatment with CF3SO2Na with tert-butyl hydroperoxide (TBHP) and a catalytic amount of copper(II) triflate (Scheme 1) [21]. The scope was rather narrow and yields were moderate to poor. In particular, enol acetate 1b, prepared from symmetrical undecan-6-one, gave a mixture of the desired α-CF3 ketone and two isomeric enol acetates 1b’. In 2014, Li, Duan and co-workers applied the conditions described by Langlois to a series of enol acetates 3 derived from aryl and heteroaryl ketones featuring a single enolizable position (Scheme 2) [22]. Notably, it was found that Cu(II) and Cu(I) salts gave similar yields. A radical trifluoromethylation was suggested for this transformation. The CF3⁺, which was generated by reaction of tert-butyl hydroperoxide with CF3SO2Na in the presence of copper(II), reacted at the more electron-rich carbon atom of the C=C double bond to give the radical species 5 that was oxidised by copper(II) into the corresponding cationic intermediate 6 via a single electron transfer (SET). Finally, the acetyl cation was eliminated to provide the α-CF3 carbonyl compound 4 (Scheme 3).

![Scheme 1: Trifluoromethylation of enol acetates by Langlois.](image-url)
Unactivated olefins are widely available substrates prone to be transformed into α-trifluoromethyl carbonyl compounds under oxidative trifluoromethylation as first reported by Maiti and co-workers in 2013. The reaction is operationally simple, conducted under air at room temperature and presents a predictable reactivity pattern as well as a wide functional group tolerance. The substrate scope was evaluated on 33 styrenes, β-substituted styrenes, heteroaromatic olefins and vinyl cycloalkanes (Scheme 4). The trifluoromethyl radical was generated from CF$_3$SO$_2$Na by means of an oxidative system comprising catalytic amounts of silver(I) nitrate and potassium persulfate K$_2$S$_2$O$_8$. Both atmospheric oxygen and K$_2$S$_2$O$_8$ can be the source of the oxygen atom of the ketone moiety. A series of experiments that include the formation of TEMPO–CF$_3$ (TEMPO: 2,2,6,6-tetramethylpiperidine 1-oxyl), the detection of Ag(0) by X-ray photoelectron spectroscopy, the retardation of the reaction in absence of air and an $^{18}$O-labeling reaction led the authors to propose the mechanism described in Scheme 4 [23].

Because some limitations appeared with heterocycles such as quinolone, indole, pyrimidine, thiophene, etc. the Maiti group reported an alternative approach toward α-trifluoromethyl ketones starting from (hetero)arylacetylenes 7 and also aliphatic terminal alkynes 8 (Scheme 5) [24]. The trifluoromethyl radical was generated from CF$_3$SO$_2$Na as indicated earlier, oxygen from air was the source of the oxygen atom, and N-methylpyrrolidine (NMP) acted as solvent and source of the hydrogen atom to convert the peroxo intermediate 9 to its hydroperoxo form 10. As proof of the mechanism, N-methylsuccinimide (11) was identified in all these reactions.

Simultaneously to Maiti’s work, Luo and co-workers reported a metal-free protocol for the trifluoromethylation of styrenes with CF$_3$SO$_2$Na, tert-butyl hydroperoxide and benzoquinone (BQ) as oxidant. The reactions were run at 80 °C for 16 h to give mixtures of α-trifluoromethyl ketones 12 and the corresponding alcohols 13 (Scheme 6) [25]. The scope was limited to simple substituted styrenes and yields were only moderate although super-stoichiometric amounts of reagents were used. The ratio 12/13 ranged from 31:69 to 66:34 but a subsequent reduction or
The use of transition metal catalysts and/or a large excess of organic oxidants can be obstacles to production. In a quest for ideal conditions, Lei and co-workers exposed heteroatom-functionalised alkenes to aerobic C-vinyl–heteroatom bond oxygenation under metal-free conditions, where oxygen from air worked in concert with a catalytic amount of potassium persulfate to activate CF₃SO₂Na (Scheme 7) [26]. The heteroatom must be a good leaving group or part of it (X = Br, Cl, NHCOMe, N₃, OP(O)(OEt)₂). A mechanistic investigation demonstrated the role of oxygen: 93% isotopic purity of the ketone product was obtained when using $^{18}$O₂; no reaction occurred under N₂ instead of O₂; K₂S₂O₈ rather than O₂ served as initiator; the radical CF₃SO₂• could either extrude SO₂ to CF₃ or react with O₂ to re-initiate the radical chain process (Scheme 7).

Vinyl azides were used by Liu and co-workers as precursors of α-trifluoromethylated ketones by reaction of CF₃SO₂Na under photoredox catalysis. The substrate scope was broad and the reaction proceeded with high functional group tolerance;
indeed, aryl-, alkyl-, hetero-functionalised terminal as well as non-terminal vinyl azides 15 were compatible with the reaction conditions. In the presence of the organic photocatalyst N-methyl-9-mesitylacridinium (17), CF₃SO₂Na was converted into CF₃⁺ upon visible-light irradiation. The CF₃⁺ radical reacted with the vinyl azide to give the iminyl radical 18 that was reduced by Mes-Acr⁻ (Mes-Acr: 9-mesityl-10-methylacridinium) into the iminyl anion 19. After protonation and hydrolysis of the imine function, the α-trifluoromethylated ketones 16 were obtained in moderate to good yields (Scheme 8) [27].

Scheme 8: Catalysed photoredox trifluoromethylation of vinyl azides.

Alkenyl MIDA (N-methylimidodiacetic) boronates 20, as functionalised alkenes, were transformed into α-trifluoromethyl-α-boryl ketones 21 by oxidative trifluoromethylation with CF₃SO₂Na. In that case, 2-iodoxybenzoic acid (IBX) was used as the oxidant to generate the trifluoromethylated radical 22 and atmospheric oxygen was the oxygen source to form the ketone (Scheme 9) [28].

Scheme 9: Oxidative difunctionalisation of alkenyl MIDA boronates.

β-Trifluoromethyl ketones could also be obtained from allylic alcohols 25 by a cascade trifluoromethylation/1,2-aryl migration. Yang, Xia and co-workers employed sodium triflinate under metal-free conditions with ammonium persulfate as the oxidant that was necessary to generate the CF₃ radical (Scheme 10) [30].

Amino- and azotrifluoromethylation of alkenes: Alkene trifluoromethylation was applied to the construction of indole, pyrazole and pyridazinone moieties via a multicomponent cascade reaction developed by Antonchick and Matcha in 2014 [31]. The method was based on the reaction between simple alkenes, sodium triflinate and diazonium salts. The CF₃ radical was produced from CF₃SO₂Na by oxidation with H₂O₂ in the presence of silver nitrate. Then, CF₃⁺ was added to the terminal position of the alkenes to give radical 26 that was trapped by the arenediazonium salt to form the radical cation 27, which was reduced into 28 prior to be converted into nitrogen heterocycles.
Scheme 10: Synthesis of β-trifluoromethyl ketones from cyclopropanols.

Scheme 11: Aryltrifluoromethylation of allylic alcohols.

Scheme 12: Cascade multicomponent synthesis of nitrogen heterocycles via azotrifluoromethylation of alkenes.
(Scheme 13). Interestingly, the method did not require stoichiometric amounts of oxidant and further transformation of the azotrifluoromethyl products allowed a Fisher indole synthesis. From a mechanistic point of view, the excited photocatalyst was oxidised by the aryl diazonium salt to produce \([\text{Ru(bpy)}_3]^{3+}\) (bpy: 2,2'-bipyridine) as the oxidant to generate the \(\text{CF}_3\) radical from \(\text{CF}_3\text{SO}_2\text{Na}\) with extrusion of \(\text{SO}_2\). Then, \(\text{CF}_3^+\) underwent a radical addition to the alkene to form the radical 29, which was trapped by the aryl diazonium salt to give the radical cation 30. Finally, 30 was reduced by \([\text{Ru(bpy)}_3]^{2+}\) to end up with the product 31 (Scheme 13).

**Oxytrifluoromethylation of alkenes:** The difunctionalisation of alkenes including a trifluoromethylation step was extended to carbon–oxygen bond formation via oxytrifluoromethylation. We have already described some examples of such a reaction leading to \(\alpha\)-trifluoromethyl ketones (vide supra) [26]. Now synthetic routes are presented leading to vicinal trifluoromethyl alcohols. In 2013 Qing and Jiang described the oxytrifluoromethylation of alkenes with hydroxamic acids 32 and \(\text{CF}_3\text{SO}_2\text{Na}\) under Langlois’ conditions with the couple \(t\text{-BuOOH}/\text{copper salt}\) (Scheme 15) [34]. A competitive formation of two radicals, \(\text{CF}_3^+\) and the amidoxyl radical [\(\text{ArN(CO}_2\text{Me)}\text{O}•\)] 33, would lead to two regioisomeric oxytrifluoromethylated products. Fortunately, this issue was solved by the primary formation of the \(\text{CF}_3\) radical and thus a regioselective addition. After optimization of the reaction conditions with styrene as model alkene, the method was applied to a wide range of alkenes featuring various functional groups. Further reduction of the N–O bond by Mo(CO)\(_6\) gave the corresponding alcohols.

A protocol free of peroxide initiator was developed by Yang, Vicic and co-workers using a manganese salt and O\(_2\) from air [35]. Styrene derivatives were transformed preferentially into hydroxytrifluoromethylated compounds 34 versus the corresponding ketones 35 in moderate to good selectivities (Scheme 16). In the case of 1,2-disubstituted alkenes, mixtures of *syn-* and *anti-* isomers were obtained. A radical pathway was supported by several observations: (i) addition of TEMPO suppressed the reaction; (ii) an induction period was observed.
followed by acceleration with consumption of styrene; (iii) vinyl triflone was detected indicating the formation of CF$_3$SO$_2$•; (iv) formation of CF$_3$SO$_3^-$ via oxidation of CF$_3$SO$_2$• (Scheme 16).

A metal-free approach with in situ generation of the peroxide from the combination of NMP and O$_2$ as the radical initiator was proposed by Lei and co-workers [36]. This method was based on a previous work by Maiti (see Scheme 5) [24] but did not require a metal to generate the CF$_3$ radical. Tertiary β-trifluoromethyl alcohols 36 were obtained in good yields from a variety of di- and trisubstituted alkenes (Scheme 17). Labelling and IR experiments were conducted to investigate the reaction mechanism as well as kinetic studies that revealed the reaction rate dependence on O$_2$ diffusion.

A case of intramolecular oxytrifluoromethylation of alkenes leading to oxazolines 37 was described by Fu and co-workers in
In this work iodobenzene diacetate (PIDA) was used as the oxidant to generate the CF$_3$ radical from CF$_3$SO$_2$Na (Scheme 18).

![Scheme 18: Intramolecular oxytrifluoromethylation of alkenes.](image)

Hydrotrifluoromethylation of alkenes: Direct alkyne hydrotrifluoromethylation by means of CF$_3$SO$_2$K under electrochemical oxidation was first reported by Tommasino and co-workers in 2002 on three alkenes but yields were below 20% due to the formation of oxidised byproducts [38]. Nicewicz and co-workers in 2013 found suitable reaction conditions for the alkyne hydrotrifluoromethylation using CF$_3$SO$_2$Na [39]. The single electron oxidation of CF$_3$SO$_2$Na was performed by visible-light activated N-methyl-9-mesitylacridinium as a photoredox catalyst. Two hydrogen atom donors, 20 mol % of methyl thiosalicylate 38 for aliphatic alkenes (or 1 equiv of thiophenol 39 for styrenyl alkenes) and 2,2,2-trifluoroethanol (TFE), worked in concert for the hydrogen atom transfer with complete suppression of the oxidised trifluoromethylated by-products. The method was regioselective for mono-, di-, and trisubstituted aliphatic alkenes and styrenyl alkenes with a broad substrate scope (Scheme 19). As an exception, 1,2-disubstituted alkenes and chalcone gave low regioselectivities with mixed Markovnikov and anti-Markovnikov products.

The CF$_3$ radical is electrophilic in nature and, as such, not prone to readily react with electron-deficient alkenes. Nevertheless, Lefebvre, Hoffmann and Rueping reported that N-substituted maleimides, maleic anhydride and dimethyl maleate were hydrotrifluoromethylated with CF$_3$SO$_2$Na in the presence of 4,4’-dimethoxybenzophenone as photosensitiser under near-UV irradiation (350 nm) and hexafluoroisopropanol (HFIP) as a proton donor (Scheme 20) [40]. The reactions were performed in batch and under continuous flow conditions with rate enhancement for the latter setup. It was proposed that the CF$_3$ radical added onto the substrate while the ketyl radical 41 was protonated by HFIP. Then, hydrogen transfer gave the hydrotrifluoromethylated product 40 and the sensitisers was regenerated (Scheme 20). In the same paper, the authors also realised the same chemical transformation under visible light irradiation at 450 nm by means of the iridium photocatalyst Ir[dF(CF$_3$)ppy]$_2$(dbbpy)PF$_6$ [(4,4’-bis(tert-buty1)-2,2’-bipyridine)bis[3,5-difluoro-2-[5-(trifluoromethyl)-2-pyridinyl]phenyl]iridium(III) hexafluorophosphate], which delivered comparable and even higher yields of the products in longer reaction times but with lower catalyst loading (1 mol %).

Both unactivated terminal alkenes and electron-deficient alkenes (Michael acceptors) were successfully hydrotrifluoromethylated under irradiation with 36 W blue LEDs in the presence of an iridium photoredox catalyst as reported by Zhu, Zhang and co-workers [41]. Of the photocatalysts tested, Ir[dF(CF$_3$)ppy]$_2$(dbbpy)PF$_6$ had appropriate redox potentials and gave the best results. A wide range of terminal alkenes featuring several functional groups reacted with exclusive anti-Markovnikov selectivity. Notably, styrene failed to react under these conditions. A selection of α,β-unsaturated electron-withdrawing motifs that included a sulfone, esters, an amide, and a ketone were investigated for the first time and the β-addition products were obtained regioselectively in moderate to good
Scheme 20: Hydrotrifluoromethylation of electron-deficient alkenes.

yields (Scheme 21). It was suggested that the methylene radical formed by addition of the CF$_3$ radical onto the alkene was reduced by the sulfinate anion and the corresponding carbanion was protonated by methanol.

Scheme 21: Hydrotrifluoromethylation of alkenes by iridium photoredox catalysis.

Halo- and pseudohalotrifluoromethylation of alkenes: The direct iodotrifluoromethylation was previously achieved by means of gaseous CF$_3$I until Liu and co-workers reported the convenient use of CF$_3$SO$_2$Na and iodide pentoxide, I$_2$O$_5$, in combination for the iodotrifluoromethylation of alkenes and alkynes (see later in the text) [42]. After an optimisation with 4-chlorostyrene, the reaction was developed with a wide range of terminal and internal alkenes bearing diverse functional groups such as halogens, nitro, sulfonate, sulfamide, carboxylate, amide, ether, carbonyl, and hydroxy that were all well-tolerated (Scheme 22). A mixed solvent system of dichloromethane and water was used in a sealed tube at 110 °C. Mechanistic studies by electron spin resonance were carried out in which both the CF$_3^*$ and the β-CF$_3$ alkyl radical intermediate were observed by using 2-methyl-2-nitrosopropane as a radical spin trap. A single-electron oxidative free-radical process was clearly ascertained. For the iodination step, the authors proposed that the β-CF$_3$ alkyl radical was intercepted by I$_2$, which was formed by a multistep redox process from I$_2$O$_5$. In continuation of this work, the same research group described the bromotrifluoromethylation of alkenes under similar reaction conditions but using sodium bromate, NaBrO$_3$, as a bromine source (Scheme 22) [43].

Scheme 22: Iodo- and bromotrifluoromethylation of alkenes by CF$_3$SO$_2$Na/I$_2$O$_5$ or CF$_3$SO$_2$Na / NaBrO$_3$.

The photoredox-catalysed chloro-, bromo- and also (trifluoromethylthio)trifluoromethylation of unactivated alkenes was studied by Liu and co-workers in 2017 (Scheme 23) [44]. The Langlois reagent was combined with N-halophthalimides 42a,b or N-trifluoromethylthiosaccharin 43 in the presence of N-methyl-9-mesitylacridinium under visible light irradiation at room temperature. Terminal, internal, and gem-substituted alkenes bearing imide, ester, amide, ketone, aldehyde and electron-rich aryl functional groups were suitable substrates. Notably, diethyl 2,2-diallylmalonate as a diene gave the
cyclised product resulting of a radical cascade. It has to be noticed that the reactions were conducted in the presence of 2 equivalents of trifluoroacetic or p-toluenesulfonic acid; yet, there was no mention of hydrotrifluoromethylated side-products. The mechanism was similar to previous examples to generate the β-CF₃ alkyl radical intermediate 44, which was trapped by halogen atom transfer from the halogenating agent. The nitrogen-centered radical 45 oxidised Mes-Acr* by a single-electron-transfer process to restart the catalytic cycle (Scheme 23).

**Carbotrifluoromethylation of alkenes:** The strategies for carbotrifluoromethylation of alkenes with CF₃SO₂Na are very much based on methods described earlier in the text: (i) reactions mediated by tert-butyl hydroperoxide and a catalytic amount of copper; (ii) metal-catalysed or metal-free reactions with K₂S₂O₈, I₂O₅ or a hypervalent iodine reagent, and (iii) photochemical activation. Most of the works concerned cascade intramolecular reactions in which a C–C bond is formed after the initial trifluoromethylation.

Therefore, Lipshutz and co-workers reported a copper-catalysed intramolecular carbotrifluoromethylation of N-arylacrylamides 46 with CF₃SO₂Na to produce oxindoles 47 [45]. Addition of the CF₃ radical to such an electron-deficient alkene should be unfavourable. However, the subsequent annulation step drove the cascade process toward oxindole synthesis. The reaction utilised Langlois’ conditions with tert-butyl hydroperoxide and a catalytic amount of Cu(II), but with 10 mol % of tetramethylethylenediamine (TMEDA). Organic solvents were replaced by pure water and the aqueous medium can be recycled up to five times. The substrate scope was large when tertiary amides were used. A secondary amide failed to give the expected product. With a substituent at the meta-position of the aniline ring, a mixture of regioisomers was obtained. Various alkenes with substituents (R³) were investigated and the oxindoles were obtained in moderate to high yields (Scheme 24).

Simultaneously, Lei and co-workers published the same reaction under slightly different conditions [46]. They used a combination CF₃SO₂Na/TBHP in the presence of catalytic amounts of copper chloride and triphenylphosphine. Trisubstituted alkenes (R³ and R⁴ ≠ H) were employed as substrates and diastereoisomers were obtained. The tert-butoxyl radical was generated from TBHP and Cu(n) via a SET process, which then, it reacted

![Scheme 23: N-methyl-9-mesityl acridinium and visible-light-induced chloro-, bromo- and SCF₃ trifluoromethylation of alkenes.](attachment:image.png)
with CF$_3$SO$_2$Na to liberate CF$_3^\cdot$. The subsequent addition of CF$_3^\cdot$ to the β-position of the C=C bond of the acrylamide gave the intermediate 48, which underwent an intramolecular radical annulation to produce the aryl radical 49. Finally, oxidation of 49 by Cu($n + 1$) and aromatisation afforded the oxindole and regenerated the copper catalyst (Scheme 25).

The same indoles bearing a 2,2,2-trifluoroethyl side-chain were also obtained in reactions performed with CF$_3$SO$_2$Na and (NH$_4$)$_2$S$_2$O$_8$ as the oxidant in the presence of a catalytic amount of AgNO$_3$ as reported by Tan and co-workers (Scheme 26) [47]. In the absence of AgNO$_3$ the reaction did not work. Notably, N-alkyl and N-aryl protected substrates worked well, whereas N-acyl and N–H derivatives failed to deliver the desired products. Mechanistically, Ag(I) was initially oxidised to Ag(II) by the persulfate anion; then, CF$_3$SO$_2^-$ was oxidised to CF$_3$SO$_2^\cdot$ that generated CF$_3^\cdot$ by release of SO$_2$. Addition of the CF$_3$ radical to the alkene led to the radical intermediate 50, which underwent intramolecular cyclisation into 51. The sulfate radical anion then oxidised intermediate 51 into the final oxindole (Scheme 26).

In an independent work Wang and co-workers demonstrated that silver nitrate was not necessary for the reaction to proceed in acetonitrile and water at 80 °C (Scheme 27) [48]. Again, N-acyl and N–H derivatives failed to deliver the desired products and meta-substituted phenyl rings produced mixtures of regioisomers. Under these metal-free conditions, it was proposed that the CF$_3$ radical was formed uniquely by reaction of CF$_3$SO$_2$Na with K$_2$S$_2$O$_8$.

---

**Scheme 24**: Carbotrifluoromethylation of N-arylacrylamides with CF$_3$SO$_2$Na / TBHP by Lipshutz.

**Scheme 25**: Carbotrifluoromethylation of N-arylacrylamides with CF$_3$SO$_2$Na / TBHP reported by Lei.

**Scheme 26**: Carbotrifluoromethylation of N-arylacrylamides with CF$_3$SO$_2$Na/(NH$_4$)$_2$S$_2$O$_8$.
N-Arylacrylamides could also react with CF$_3$SO$_2$Na under metal-free conditions by replacing tert-butyl hydroperoxide or the persulfate by hypervalent iodine oxidants such as iodo-benzene diacetate (PIDA, Scheme 28) [49], or iodo-benzene bis(trifluoroacetate) (PIFA) [50]. Fu and co-workers proposed the reaction mechanism depicted in Scheme 28. PIDA reacted with CF$_3$SO$_2$Na under heating conditions to produce two radicals: CF$_3^*$ along with PhI’OAc. Addition of the CF$_3$ radical to the alkene followed by intramolecular cyclisation mediated by PhI’OAc gave the desired oxindole with release of PhI and AcOH (Scheme 28) [49].

The intramolecular carbotrifluoromethylations of alkenes from acrylamides and methacrylamides, so far described, provided oxindoles via a 5-exo trig cyclization. Starting from cinnamamides 53, Mai, Xiao and co-workers reported a 6-endo trig cyclisation leading to 3,4-disubstituted dihydroquinolin-2(1H)-ones 54 (Scheme 30) [52]. Ag(I) was oxidised by the persulfate anion (S$_2$O$_8^{2–}$) to generate the Ag(II) cation and the sulfate radical anion; then, the Ag(II) oxidised CF$_3$SO$_2$Na into CF$_3^*$ with extrusion of SO$_2$. The CF$_3$ radical reacted with the C=C double bond of the cinnamamide leading to the intermediate 55 that underwent 6-endo trig cyclisation to 56 that finally aromatised to the desired product 54 trans-selectively (Scheme 30).

In 2016, Xia and co-workers described a metal-free, UV-light-mediated difunctionalisation of alkenes with CF$_3$SO$_2$Na for the synthesis of phenanthrene and anthrone derivatives [53]. The substrates were either α,β-unsaturated ketones 57 (Scheme 31a) or γ,δ-unsaturated ketones 58 (Scheme 31b). Benzenophene (BP) or anthracene-9,10-dione (AQ) were used as sensitizers under irradiation using a UV lamp at 280 nm. A radical pathway that involves CF$_3^*$ was established after a negative reaction in the presence of TEMPO (TEMPO–CF$_3$ was detected by GC–MS).
Scheme 30: Trifluoromethylation/cyclisation of N-arylcinnamamides: Synthesis of 3,4-disubstituted dihydroquinolin-2(1H)-ones.

Scheme 31: Trifluoromethylation/cyclisation of aromatic-containing unsaturated ketones.

Scheme 32: Chemo- and regioselective cascade trifluoromethylation/heteroaryl ipso-migration of unactivated alkenes.

Scheme 33: Copper-mediated 1,2-bis(trifluoromethylation) of alkenes.

An example of difunctionalisation of unactivated alkenes with CF₃SO₂Na and an heteroaryl group in which the heteroarylation was realised by a distal heteroaryl ipso-migration was provided in 2017 by Zhu and co-workers (Scheme 32) [54]. A variety of nitrogen containing heteroaryl groups showcased the migratory aptitude selectively in the presence of an aryl or an alkyl group. The number of methylene units between the alkene and the tertiary alcohol function was studied: n = 0, 2, and 3 were suitable for generating thermodynamically favoured 3, 5, and 6-membered cyclic transition states; the reaction failed with n = 1, 4. Experimental and computational studies allowed the authors to propose the mechanism depicted in Scheme 32. First, the CF₃ radical was generated from CF₃SO₂Na and PIFA. Then, addition of CF₃⁺ to the alkene gave the alkyl radical 59 that added to the ipso position of the heteroaryl group to form radical 60. Next, homolysis of the C–C σ-bond in 60 provided the more stable hydroxalkyl radical 61. This radical was oxidised by PIFA to yield the cationic intermediate 62, which finally lost a proton to furnish the reaction product.

1,2-Bis-trifluoromethylation of alkenes: Alkenes were efficiently and chemoselectively bis-trifluoromethylated under Langlois’ conditions with CF₃SO₂Na. Indeed, Qing and co-workers prepared 1,2-bis(trifluoromethylated) compounds 63 with in situ generated CF₃ radicals (Scheme 33). In order to avoid the formation of dimerised side products, it was demonstrated that an increase of the CF₃ radical concentration, obtained by increasing the amount of copper catalyst, was beneficial to the chemoselectivity. Both styrene derivatives and terminal unactivated alkenes were suitable substrates in this transformation but not internal alkenes [55].
C<sub>sp2</sub>–CF<sub>3</sub> bond-forming reactions

Direct trifluoromethylation of arenes and heteroarenes: In 1991, Langlois and co-workers reported the first trifluoromethylation of aromatic compounds with sodium trifluoromethanesulfinate under oxidative conditions (Scheme 34) [16]. The scope was quite narrow with electron-rich aromatics and mixtures of regioisomers were often obtained. For instance, from aniline, two isomers were obtained in 13% overall yield, and from 1,3-dimethoxybenzene, four products (regioisomers + bis-CF<sub>3</sub> compounds) were obtained in 90% overall yield. For this transformation, a radical process was proposed: the trifluoromethyl radical CF<sub>3</sub>• was generated by reaction of tert-butyl hydroperoxide with CF<sub>3</sub>SO<sub>2</sub>Na in the presence of a copper(II) catalyst (Scheme 34).

Substrates with sensitive functional groups may not be tolerated under such reaction conditions and a large excess amount of peroxide was necessary to reach high yields. That is how, in 1998, Smertenko and co-workers described a milder electrochemical trifluoromethylation of a series of aromatic compounds using CF<sub>3</sub>SO<sub>2</sub>Na in acetonitrile [56]. Furthermore, the electrochemical oxidation of the trifluoromethysulfinate anion (from CF<sub>3</sub>SO<sub>2</sub>K) generated the trifluoromethyl radical for the reaction of electron-rich aromatics and alkenes [38].

It is twenty years after Langlois’ pioneering work that the direct trifluoromethylation of heteroaromatic compounds was re-investigated by Baran and co-workers in 2011 [57]. This group reported a C–H trifluoromethylation protocol that was operationally simple, scalable, achieved at room temperature, working with a variety of electron-deficient and -rich heteroaromatic systems tolerating various functional groups such as unprotected alcohols, amines, ketones, esters, halides and nitriles. Importantly, the trifluoromethylation proceeded at the innate reactive positions of the heterocycles; however, it was noticed that the regioselectivity can be tuned simply by solvent choice. Langlois and others employed catalytic metal salts for reaction initiation but Baran’s group demonstrated that metal additives were not required for a productive reaction, only trace metals found in Langlois’ reagent could be responsible for reaction initiation. The scope was evaluated on pyridines, pyrroles, indoles, pyrimidines, pyrazines, quinoxalines, deazapurines, thiadiazoles, uracils, xanthenes and pyrazolopyrimidines (Scheme 35). The combination of previous studies with new observations allowed to propose a putative mechanism (Scheme 35) as well as unproductive pathways (formation of CF<sub>3</sub>H from CF<sub>3</sub>• by abstraction of a hydrogen atom or reaction of CF<sub>3</sub>• with isobutene generated from t-BuOOH).

Substrates with sensitive functional groups may not be tolerated under such reaction conditions and a large excess amount of peroxide was necessary to reach high yields. That is how, in 1998, Smertenko and co-workers described a milder electrochemical trifluoromethylation of a series of aromatic compounds using CF<sub>3</sub>SO<sub>2</sub>Na in acetonitrile [56]. Furthermore, the electrochemical oxidation of the trifluoromethysulfinate anion (from CF<sub>3</sub>SO<sub>2</sub>K) generated the trifluoromethyl radical for the reaction of electron-rich aromatics and alkenes [38].

This oxidative trifluoromethylation method was exploited for the synthesis of modified nucleosides, in particular 8-CF<sub>3</sub>-2’-deoxyguanosine and 8-CF<sub>3</sub>-inosine in 39 and 73% yields, respectively [58].

The same copper-free method was applied for the trifluoromethylation of a variety of electron-deficient 4-substituted acetanilides or anilines (Scheme 36). In these reaction conditions, Cao’s group reported that acetanilides or anilines featuring electron-donating substituents at the para-position of the acetamino group afforded mixtures of isomeric C–H trifluoromethylation products in moderate yields. However, with substrates bearing electron-withdrawing groups, ortho-CF<sub>3</sub> acetanilides or anilines were obtained as sole products [59].

To meet high expectations of environmentally low impact chemical reactions, Lipshutz and co-workers carried out the trifluoromethylation of heterocycles using aqueous micellar conditions based on the surfactant TPGS–750–M in water at room temperature. The trifluoromethyl radical was generated from CF<sub>3</sub>SO<sub>2</sub>Na and t-BuOOH. In comparison to Baran’s
Beilstein J. Org. Chem. 2017, 13, 2764–2799.

Scheme 36: Trifluoromethylation of acetanilides and anilines.

results, in all cases, the yields were improved. Advantageously, the aqueous medium can be recycled (Scheme 37) [60].

Scheme 37: Trifluoromethylation of heterocycles in water.

Even though it is a proven fact after 2011 and Baran’s work that no-added metal trifluoromethylation with CF$_3$SO$_2$Na are highly efficient, the original Langlois’ conditions were nevertheless applied to a series of heteroarenes. Li and co-workers reported the synthesis of 3-trifluoromethylcoumarins 64 by Cu(I)-catalysed trifluoromethylation with CF$_3$SO$_2$Na and t-BuOOH in a continuous-flow reactor [61]. After optimisation of the reaction conditions in batch, the optimal reaction conditions were established in a continuous-flow reactor at a flow rate of 100 µL min$^{-1}$ at 60 °C for 40 min. The substrate scope was evaluated on 11 coumarins and showed that both electron-rich and electron-deficient functional groups were tolerated (Scheme 38).

Scheme 38: Trifluoromethylation of coumarins in a continuous-flow reactor.

Zou and co-workers applied the conditions described by Langlois or Baran (CF$_3$SO$_2$Na/t-BuOOH/cat. Cu(II) or CF$_3$SO$_2$Na/t-BuOOH, respectively) for the trifluoromethylation of coumarins but no reaction was observed. By testing other oxidants, they found that Mn(OAc)$_3$ was a good oxidant for this reaction and allowed to carry out the trifluoromethylation exclusively at the α-position of the carbonyl group in the pyranone ring. The substrate scope was large and included 17 coumarins, 2 quinolines and 3 pyrimidinones. With coumarins bearing electron-donating groups on the phenyl ring, the 3-trifluoromethylated compounds were obtained in 50–56% yields. However, coumarins bearing electron-withdrawing groups gave yields up to 70%. As for the mechanism, the trifluoromethyl radical was generated from CF$_3$SO$_2$Na and Mn(OAc)$_3$, then CF$_3$• added regioselectively onto the coumarin to give intermediate radical 65, which was oxidised by Mn(OAc)$_3$ to form the carbocation 66 and, after deprotonation, the trifluoromethyl compounds (Scheme 39) [62].

The same group also reported a straightforward method for the trifluoromethylation of pyrimidinones and pyridinones under the same reaction conditions. 5-Trifluoromethylpyrimidinones and 3-trifluoromethylpyridinones were selectively obtained in moderate to good yields (Scheme 40). It was observed that the substituent R$^1$ provided no stabilisation for the radical intermediate, so the less bulky substituents at 6-position of pyrimidinones or 4-position of pyridinones facilitated the trifluoromethyl radical attack [63].

Catalytic amounts of phosphovanadomolybdic acid, a heteropolyacid catalyst (HPA), was used by Mizuno, Yamaguchi and co-workers for the oxidative C–H trifluoromethylation of arenes and heteroarenes in the presence of CF$_3$SO$_2$Na and O$_2$ as the terminal oxidant. This method allowed the trifluoromethylation of arenes bearing electron-donating as well as electron-withdrawing groups in moderate to good yields (Scheme 41) [64]. It has to be noted that bis-CF$_3$ products as well as regioisomers were also characterised or detected in small amounts in most cases. A radical mechanism was proposed as described in Scheme 41.

Imidazopyridines have demonstrated many interesting features toward biological activities and the incorporation of a trifluoromethyl group into such architectures was expected to alter their properties. Therefore, Hajra and co-workers reported a direct and regioselective method for the trifluoromethylation of imidazopyridines 67 and other imidazoheterocycles 68 [65]. The

Scheme 41: Phosphovanadomolybdic acid-catalysed direct C-H trifluoromethylation.

Combination CF$_3$SO$_2$Na/r-BuOOH/cat. AgNO$_3$ at room temperature under air was applied to 17 imidazopyridines and 3 imidazo-heterocycles (Scheme 42). Good yields were obtained when the phenyl moiety was substituted by electron-donating groups. As a result of absence of reactivity in presence of the radical scavenger TEMPO, a radical pathway was proposed. Under argon atmosphere, only trace amounts of the CF$_3$ product were obtained clearly indicating the crucial role of aerial oxygen in the catalytic cycle (see mechanism in Scheme 42).

Simultaneously, Tang and co-workers reported a greener strategy for the trifluoromethylation of imidazoheterocycles with CF$_3$SO$_2$Na in a recyclable mixed medium of 1-butyl-3-methylimidazolium tetrafluoroborate ([Bmim]BF$_4$) and water [66]. The substrate scope was investigated on 11 imidazothiazoles, 13 imidazo[1,2-$\alpha$]pyridines and 6 imidazoles (Scheme 43). The reaction was simple, achieved at room temperature and had a good tolerance for various functional groups. However, for the trifluoromethylation of imidazoles, it was essential to have a phenyl as a substituent in order to get good yields. A radical mechanism was proposed but the role of oxygen was not discussed.

Aminoquinoline derivatives are found in naturally occurring and synthetic bioactive compounds, most notable for their antimalarial activity. So, it was not surprising that trifluoromethyl analogues were prepared in particular by means of CF$_3$SO$_2$Na. Indeed, 5-trifluoromethyl-8-aminoquinoline derivatives 69 were regioselectively synthesised under various reaction conditions. Cai and co-workers reported the trifluoromethylation of 8-aminoquinolines selectively at position 5 by using CF$_3$SO$_2$Na, CuBr$_2$ in a catalytic amount and azobisisobutyronitrile (AIBN) as an oxidant (Scheme 44) [67]. This process had a broad tolerance toward a wide range of functional groups. Aliphatic amides, aromatic amides and carboxamides with hetero-
cyclic substituents were compatible with the reaction conditions. A series of control experiments that included the inhibition of the reaction in the presence of TEMPO, deuteration and isotope effect experiments were carried out and led the authors to propose the single-electron transfer mechanism presented in Scheme 44.

Simultaneously, Shen, Zhang and co-workers reported a milder regioselective trifluoromethylation of 8-aminquinolines using the supported catalyst CS@Cu(OAc)$_2$ (CS = chitosan), potassium persulfate as the oxidant and CF$_3$SO$_2$Na as the CF$_3^-$ source (Scheme 45) [68]. After optimisation of the reaction conditions, the authors studied the effect of structural variations in the substrate (R$^1$ = aryl, heteroaryl, alkyl; R$^2$ = H, 6-OMe, 2-Me). Aniline amides gave no conversion nor did quinoline having an ester group at the 8 position instead of the 8-amino group. The chitosan-based copper catalyst was efficiently reused in five cycles of this heterogeneous trifluoromethylation.

In 2017, Lu, Weng and co-workers reported a protocol for the para-selective trifluoromethylation of naphthyramide 70, instead of the previously studied quinolines, with CF$_3$SO$_2$Na, tert-buty1 hydroperoxide and Cu(OAc)$_2$·H$_2$O as oxidant (Scheme 46) [69].

tert-Butyl hydroperoxide could be replaced by sodium persulfate as demonstrated in 2016 by Gong and co-workers who re-
ported a direct C–H trifluoromethylation of arenes with CF$_3$SO$_2$Na in a mixture of water and acetonitrile (Scheme 47) [70]. Various trifluoromethylated arenes were obtained in moderate to excellent yields. However, to achieve high yields in this trifluoromethylation, one (or more) alkoxy group(s) must be present on the arenes in order to stabilise the free-radical intermediate (see mechanism in Scheme 47). Control experiments such as the trapping of the trifluoromethyl radical with the scavenger TEMPO or with benzoquinone were performed and a radical process was proposed. This mild and safe transformation had a good tolerance for various functional groups.

In 2013, Shibata and co-workers reported a transition-metal-free oxidative trifluoromethylation of arenes with CF$_3$SO$_2$Na and phenyliodine bis(trifluoroacetate) (PIFA) instead of tert-butyl hydroperoxide as the oxidant in hexafluoroisopropanol (HFIP) at room temperature [71]. In order to obtain good results for this transformation, it should be noted that the electron-donating nature of the aromatic substituents was a crucial point. In the case of unsymmetrical biaryl substrates, mixtures of regioisomers at C4 and C5 were obtained (Scheme 48). In the reaction mechanism, PIFA played a dual role in the activation of the arene via a π-complex and in the generation of the CF$_3$ radical from CF$_3$SO$_2$Na.

More recently, Maruoka and co-workers reported the synthesis of trifluoromethylated coumarin 71 and flavone 72 with CF$_3$SO$_2$Na (2 equiv), the hypervalent iodine F$_5$-PIFA (pentafluorophenyliodine bis(trifluoroacetate)) (2 equiv) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ, 0.6 equiv). The
trifluoromethylated compounds were obtained in moderate yields (Figure 1) [50].

To avoid the use of transition-metal catalysts and/or an excess amount of oxidants, the Itoh group reported a simple metal-free, direct trifluoromethylation of arenes and heteroarenes using a photoredox-based process under visible-light irradiation. This method used CF$_3$SO$_2$Na as source of the trifluoroethyl group and a catalytic amount of anthraquinone-2-carboxylic acid (AQN-2-CO$_2$H). The scope was achieved on arenes and heteroarenes (10 examples). Once more, electron-rich aromatic compounds were converted into the corresponding trifluoromethylated products in good yields (Scheme 49). The oxidation–reduction potentials were determined by cyclic voltammetry and a catalytic cycle was proposed in which the CF$_3$ radical was generated from CF$_3$SO$_2$Na via the organocatalyst AQN-2-CO$_2$H and visible light (Scheme 49) [72].

Rueping’s group described three examples of prototypical (hetero)aromatic substrates that were trifluoromethylated with CF$_3$SO$_2$Na in the presence of 4,4’-dimethoxybenzophenone as photosensitiser under near-UV irradiation (350 nm) and HFIP as a proton donor [40]. More recently, Yuan and co-workers reported an efficient and operationally simple method for the direct trifluoromethylation of a wide variety of arenes and heteroarenes under visible-light irradiation [73]. The substrate scope was evaluated on 30 arenes and heteroarenes using 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) as photocatalyst and CF$_3$SO$_2$Na as the CF$_3$ radical source. The reaction conditions tolerated a broad range of functional groups and the yields ranged from 31 to 68% (Scheme 50). During the process, the quinone was converted into hydroquinone and a regeneration process was established by passing through a cartridge of MnO$_2$. A mechanism for this transformation was proposed as a result of electron paramagnetic resonance spectroscopy experiments (Scheme 50).

In 2016, Li, Mi and co-workers reported a simple and clean approach for the direct trifluoromethylation of unactivated arenes and heteroarenes through a photoreduction without any metal catalyst nor oxidant. The radical initiators were as simple as acetone or diacetyl for the generation of CF$_3$ radicals. Indeed, the authors demonstrated that photoexcited acetone was capable to trigger the trifluoromethylation reaction efficiently. So, acetone in this process was used as solvent and photosensitiser. The reactions were carried out under UV irradiation with either a 300 W xenon lamp (emission wavelengths between 200 and 1000 nm) or the photoreactor ($\lambda = 254$ nm). This photochemical process allowed the synthesis of trifluoromethylated arenes (Scheme 51), but also heteroarenes and nucleosides in good
Trifluoromethylation of arenediazonium compounds:

Langlois’ conditions were applied in the copper-mediated Sandmeyer-type trifluoromethylation of arenediazonium compounds. The scope of this reaction was investigated on 12 arenediazonium compounds. The mild reaction conditions allowed the tolerance of various groups such as ester, aryl, nitrile, amine, ketone, nitro, sulfonate and bromo (Scheme 52). In this process, the CF₃ radical was stabilised by the presence of an excess amount of CuBF₆(MeCN)₄ and the tridentate ligand 2,2',6',2''-terpyridine (tpy) [76]. Notably, a change in the copper source caused the predominant trifluoromethanesulfonylation of the substrate (introduction of the SO₂CF₃ group, vide infra). A one-pot version starting from anilines was recently developed [77].

Trifluoromethylation of aryl-, vinyl-, alkynylboronic acids:

In 2012, Sanford and co-workers reported, for the first time, the copper-mediated radical trifluoromethylation of aryl- and heteroarylboronic acids using CF₃SO₂Na and TBHP as an oxidant. The substrate scope was evaluated on 24 aryl and heteroaryl boronic acids. The process was compatible with various functional groups. Aromes bearing electron-donating groups reacted in excellent yields under the CuCl-mediated conditions. However, arones with electron-withdrawing substituents necessitated (MeCN)₄CuPF₆ and a base, NaHCO₃, to allow the trifluoromethylation to proceed in good yields (Scheme 53) [78].

In the continuity of Sanford’s work, Beller’s group reported the synthesis of trifluoromethylated arenes from arylboronic acids as well as trifluoromethylated vinylarenes [79]. The substrate scope was realised on 12 arylboronic acids and 8 vinylboronic acids (Scheme 54). The protocol was robust and tolerated various functional groups. However, large excesses of both CF₃SO₂Na and TBHP were required. In this process, a ligand, 2,4,6-collidine, was used in order to increase the yield of the transformation. For the styrenylboronic acids, electron-withdrawing and electron-donating substituents on the aryl ring were compatible with the reaction conditions. Based on experimental observations, the authors proposed two possible mechanisms for this trifluoromethylation (Scheme 54).
transmetallation of the boronic acid with the active Cu(II) species 73 gave the arylcopper(II) complex 74, which reacted with CF$_3^+$ to afford the arylcopper(III) complex 75. Next, a reductive elimination gave the trifuoromethylated product with release of the Cu(I) complex 76 that was re-oxidised to the active copper(II) catalyst 73 to close the cycle. In path B, the copper(II) complex 73 reacted with CF$_3^+$ to form the copper(III) complex 77, which after transmetallation with the boronic acid gave the same intermediate 75.

![Reaction mechanism diagram](image)

Trifluoromethylation of potassium organotrifluoroborates: In 2013, Molander, Rombouts and co-workers simply applied the reaction conditions described by Sanford for boronic acids to a series of unsaturated potassium organotrifluoroborates (Scheme 55) [80]. In the case of aryl- and heteroaryltrifluoroborates, electron-rich substrates were efficiently trifluoromethylated although the increase of the steric hindrance caused a decrease in yields. On the other hand, the yields obtained with electron-poor potassium organotrifluoroborates were lower. In the same paper, the preparation of trifluoromethyl-substituted alkynes and alkenes from alkynyl- and alkenyltrifluoroborates was demonstrated albeit in moderate yields. The yields of the trifluoromethylation of alkenyltrifluoroborates strongly depended on the substitution of the olefin (Scheme 55).

**Scheme 55:** Oxidative trifluoromethylation of unsaturated potassium organotrifluoroborates.

Simultaneously, Dubbaka and co-workers reported the trifluoromethylation of aryl-, heteroaryl-, and vinyltrifluoroborates with CF$_3$SO$_2$Na (Scheme 56) [81]. The authors used basically the same protocol as Sanford and Molander but observed that a more diluted reaction medium gave improved reaction yields.

**Scheme 56:** Oxidative trifluoromethylation of (hetero)aryl- and vinyltrifluoroborates.

Trifluoromethylation of alkenes by decarboxylation: Liu and co-workers were the first to describe the copper-catalysed decarboxylative trifluoromethylation of $\alpha$,$\beta$-unsaturated carboxylic acids in the presence of CF$_3$SO$_2$Na and TBHP [82]. Various (hetero)arenes were compatible with these reaction conditions (Scheme 57); nevertheless, cinnamic acids bearing electron-donating groups afforded the corresponding products in better yields. The stereoselectivity was moderate to high from 76:24 to 99:1. Interestingly, aryls bearing a nitro or a chloro substituent gave the corresponding $\alpha$-trifluoromethyl ketones.
This process was interesting for the construction of C-vinyl–CF$_3$ bonds via a radical addition–elimination (Scheme 57).

Soon after, Maiti and co-workers reported an iron-mediated trifluoromethylation of α,β-unsaturated carboxylic acids with CF$_3$SO$_2$Na, iron(III) chloride and potassium persulfate as oxidant [83]. The substrate scope was evaluated on 10 cinnamic acids (Scheme 58). Under these conditions, both electron-rich or electron-poor arenes gave the vinylic CF$_3$ products in good yields and with excellent stereoselectivities. A mechanism was proposed starting from the generation of iron carboxylate and the reaction with the CF$_3$ radical followed by extrusion of CO$_2$ and radical coupling (Scheme 58).

Two major drawbacks appeared in the above-mentioned works: halo-substituted aryl derivatives failed to give the expected products and α,β-unsaturated carboxylic acids substituted at the β-position were not studied. Accordingly, Li, Duan and co-workers reported a copper/silver-catalysed decarboxylative trifluoromethylation of α,β-unsaturated carboxylic acids with CF$_3$SO$_2$Na that tolerated various substrates bearing halogens as well as α,β-unsaturated carboxylic acids substituted at the β-position (Scheme 59) [84]. It was even noticed that β-methyl or β-phenyl-substituted cinnamic acids gave better yields compared to unsubstituted cinnamic acid. All products were obtained with excellent stereoselectivity. To gain insight about the mechanism, the authors used TEMPO as a radical scavenger and concluded that CF$_3$ radical was involved in this reaction (Scheme 59).

A metal-free protocol for the decarboxylative trifluoromethylation of cinnamic acids with CF$_3$SO$_2$Na was reported by Shang, Liu and co-workers using iodine pentoxide (I$_2$O$_5$) as oxidant. The substrate scope was evaluated on 9 α,β-unsaturated carboxylic acids substituted by electron-rich aryls (Scheme 60) [85]. The mild conditions gave the trifluoromethylated products in excellent yields with high stereoselectivities. Nevertheless, the reaction conditions did not allow the formation of products with electron-withdrawing substituents on the aromat-
ic ring, such as the nitro group. The case of halogen-substituted cinnamic acids was not studied. Finally, mechanistic studies conducted by electron-spin resonance and by spin trapping technology suggested a free-radical addition–elimination process (Scheme 60).

**Scheme 60:** I$_2$O$_5$-Promoted decarboxylative trifluoromethylation of cinnamic acids.

**Trifluoromethylation of alkenes by denitrification:** Another route to the C$_{\text{vinyl}}$–CF$_3$ bond is the denitrative trifluoromethylation of β-nitrostyrenes. More generally, this transformation has attracted much attention as a useful method for the construction of C$_{\text{vinyl}}$–R moieties. In 2016, Li, Duan and co-workers reported this trifluoromethylation by means of CF$_3$SO$_2$Na catalysed by silver nitrate in the presence of a large excess of di-tert-butyl peroxide (DTBP) as the oxidant and tetrabutylammonium iodide (TBAI) as a phase-transfer catalyst (Scheme 61) [86]. The substrate scope was evaluated on 16 β-nitrostyrenes and substrates bearing electron-donating groups as well as halides afforded the corresponding trifluoromethylstyrenes in moderate to good yields. However, the substrates with electron-withdrawing groups (CN, NO$_2$) led to trifluoromethylated products in poor yields. This transformation was highly stereoselective, only (E)-isomers of the products were obtained. Experiments in the presence of 1,1-diphenylethylene as a radical scavenger led the authors to propose a radical process for this reaction (Scheme 61).

**Scheme 61:** Silver(I)-catalysed denitrative trifluoromethylation of β-nitrostyrenes.

**Trifluoromethylation of styrene derivatives:** An obviously simple route for the synthesis of trifluoromethylated styrene derivatives is the direct C–H trifluoromethylation of alkenes. Very recently, Shen, Loh and co-workers reported a copper-catalysed direct trifluoromethylation of the vinyllic C$_{\text{sp2}}$–H bond of styrene derivatives with CF$_3$SO$_2$Na, di-tert-butyl peroxide, 10 mol % of copper(I) iodide, 1-methylimidazole (NMI) as ligand to copper and tetrabutylammonium iodide (TBAI) as additive (Scheme 62) [87]. The mild reaction conditions allowed a wide variety of functional groups to be tolerated and afforded a series of trifluoromethylated styrenes in moderate to good yields and with excellent stereoselectivity. However, aliphatic alkenes or styrenes bearing electron-withdrawing groups were not suitable for this reaction. Based on control experiments, the authors proposed a radical pathway for this reaction (Scheme 62).

**Scheme 62:** Copper-catalysed direct trifluoromethylation of styrene derivatives.
Trifluoromethylation of enamines: Highly functionalised alkenes represented by (Z)-methyl-3-(phenylamino)acrylates were subjected to Baran’s conditions for the synthesis of β-trifluoromethylated enamines. Indeed, Jiang, Wu and co-workers reported mild, transition-metal-free conditions, insensitive to air and water, for the synthesis of a wide range of CF₃-enamines using CF₃SO₂Na and TBHP as initiator and oxidant (Scheme 63) [88]. Moderate to good yields were obtained and only (E)-isomers were observed. The authors carried out several experiments such as the use of TEMPO or 2,6-di-tert-butyl-4-methylphenol (BHT) as scavengers in order to investigate the mechanism of this reaction (Scheme 63).

Trifluoromethylation of alkynes: Together with the iodonitrile trifluoromethylation of alkenes leading to Cₛ–CF₃ products (see Scheme 22), the Liu group extended the free-radical iodonitrile trifluoromethylation to alkynes with the combination of CF₃SO₂Na/I₂O₅ and assistance of NaHCO₃ (Scheme 64) [42]. The substrate scope was carried out on various aryl-substituted alkynes and one propargylic ester; (E)-CF₃ alkenyl iodides were obtained stereoselectively in moderate to high yields via a free-radical process.

Trifluoromethylation of isonitriles: The synthesis of trifluoromethylated phenanthridines 79 from aryl isonitriles has been the recent subject of several investigations as potential structural unit in pharmaceuticals. In this context, CF₃SO₂Na was used by Zhang and co-workers in a silver-catalysed tandem trifluoromethylation and cyclisation of aryl isonitriles (Scheme 65) [89]. A wide variety of aryl isocyanides were transformed into the corresponding phenanthridines in moderate to good yields; some regioisomers were obtained depending on the biphenyl substituents. Here again, a radical pathway was established for this transformation (Scheme 65).

Simultaneously, Lu and co-workers reported a transition-metal-free synthesis of the trifluoromethylphenanthridine 79a in 58% yield using the system CF₃SO₂Na/K₂S₂O₈/K₂CO₃ in H₂O/CH₃CN at 80 °C [90]. In addition, Maruoka and co-workers used the system CF₃SO₂Na/PIFA/AcONa in AcOEt at room
temperature for 1.5 h to get 79a in 74% yield [50]. Mid 2017, Ao, Liu and co-workers exploited the reaction conditions developed previously for the photoredox trifluoromethylation of vinyl azides (see Scheme 8) in the synthesis of fluorinated phenanthridines 79. The yields were moderate to good and regioselectivity issues appeared depending on the biphenyl substituents (Scheme 66) [91].

Scheme 66: Photoredox trifluoromethylation of 2-isocyanoanobiphenyls.

Csp–CF₃ bond-forming reactions

For the synthesis of trifluoromethylacetylenes 81, a copper-mediated trifluoromethylation of potassium alkynyltrifluoroborates 80 with CF₃SO₂Na was developed by Dubbaka and co-workers (Scheme 67) [92]. The scope was large including aryl, heteroaryl, alkenyl, and aliphatic alkynyltrifluoroborates and the yields were moderate. Mechanistically, the CF₃ radical was generated under Langlois’ conditions by means of tert-butyl hydroperoxide and CuCl.

Scheme 67: Trifluoromethylation of potassium alkynyltrifluoroborates with CF₃SO₂Na.

N–CF₃ bond-forming reactions

C-, O-, and S-trifluoromethylated compounds are common in the field of biologically active molecules unlike the N–CF₃ motif despite the huge number of nitrogen-containing pharmaceuticals. In 2017, Selander and co-workers reported a chemoselective N-trifluoromethylation of nitrosoarenes 82 in the presence of CF₃SO₂Na, a catalytic amount of copper(II), tert-butyl hydroperoxide as oxidant and hydroquinone as additive [93]. No reaction was observed in the absence of the copper salt. The reaction conditions were suitable with a wide variety of functionalised nitrosoarenes and the corresponding trifluoromethylated hydroxylamines 83 were obtained in moderate to good yields (Scheme 68). The authors proposed a radical mechanism with two pathways for the generation of the CF₃ radical, either by copper species or by tert-ButO• (Scheme 68). Interestingly, N–CF₃ anilines were easily obtained after reduction of the N–O bond.

Scheme 68: N-trifluoromethylation of nitrosoarenes with CF₃SO₂Na (SQ: semiquinone).

S–CF₃ bond-forming reactions

Synthetic routes to trifluoromethylthiolated compounds are diverse, one is the S–CF₃ bond formation (see next section for C–SCF₃ bond formation). For this purpose, Langlois and co-workers used aliphatic and aromatic disulfides, RS–SR, which reacted with CF₃SO₂Na in the presence of an oxidant, t-BuOOH providing the best yields, to afford the trifluoromethyl thioethers (Scheme 69a) [20]. Other oxidants such as K₂S₂O₈ and (NH₄)₂Ce(NO₃)₆ displayed lower reactivity and selectivity. Only one sulfenyl moiety of the disulfide was trifluoromethylated in this approach, the second being oxidised without trifluoromethylation. Aryl disulfides exhibited a lower
reactivity and selectivity because side radical aryl C–H trifluoromethylation occurred competitively. This approach was applied to the synthesis of S-trifluoromethyl-containing amino acids $85$ from dithio-amino acids $84$ (Scheme 69b) [94].

Apart from disulfides, thiols were also used as substrates by Yi and co-workers to produce several trifluoromethyl thioethers and aliphatic trifluoromethylthiols. Their contribution was inspired by the previous work of Liu, using iodine pentoxide as an inexpensive inorganic oxidant [42] to generate the CF$_3$ radical and release of iodine, which then reacted with the thiol to first form the corresponding disulfide $86$ (detected as reaction intermediate) and further the sulfenyl iodide $87$. The final SCF$_3$ product was the result of the reaction of CF$_3•$ with either $86$ or/and $87$ (Scheme 70) [95]. The reaction performed well only at high reaction temperature (110 °C) for both thiophenols, benzylthiols and mercapto derivatives. The same research group recently reported different reaction conditions to obtain the same SCF$_3$ products by means of CF$_3$SO$_2$Na in the presence of potassium persulfate and a catalytic amount of silver nitrate at 80 °C in acetonitrile and water [96].

2 Trifluoromethylsulfenylation

In the early development of the direct electrophilic trifluoromethylthiolation, trifluoromethanethiol (CF$_3$SH), trifluoromethanesulfenyl chloride (CF$_3$SCl), and bis(trifluoromethyl) disulfide (CF$_3$SSCF$_3$) were the only reagents available, but their gaseous and toxic nature precluded a wider use. Fortunately, in the recent years, a collection of stable and easy-to-handle reagents was designed to perform efficient trifluoromethylthiolations [97]. Less sophisticated and suitable for large scale industrial use, CF$_3$SO$_2$Na was first used in trifluoromethylthiolation reactions in 2015 by Yi, Zhang and co-workers who reported the direct copper-catalysed trifluoromethylthiolation of indoles, pyrroles and enamines in the presence of potassium persulfate and a catalytic amount of silver nitrate at 80 °C in acetonitrile and water [96].

The same authors further demonstrated that the trifluoromethylsulfonylation can be conducted under metal-free conditions by replacing CuCl with trimethylsilyl chloride (TMSCl) to generate the cation CF$_3$S$^+$ in the presence of (EtO)$_2$P(O)H [99]. Again, the electrophilic trifluoromethylsulfenylation of indoles was studied but also the trifluoromethylthiolation of electron-rich arenes (Scheme 72). Using this protocol, trifluoromethylsulfenylated compounds were obtained in moderate to excellent yields. Compared to the CuCl-mediated approach, this method directly converted CF$_3$SOH into CF$_3$S$^+$ by reaction with TMSCl (Scheme 72). Based on this above-mentioned work and simultaneously to the metal-free approach, Cai and co-workers reported the direct trifluoromethylsulfenylation of indoles, pyrroles and enamines, with CF$_3$SO$_2$Na, triphenylphosphine and N-chlorophthalimide without added metal and at room temperature (Scheme 73) [100]. In general, the substrates were successfully trifluoromethylsulfenylated in moderate to excellent yields by in situ generated CF$_3$SCl as suggested by $^{19}$F NMR studies and previous literature reports.
Different phosphorus reductive reagents were evaluated by Liu, Lin and co-workers. It was found that phosphorus trichloride (PCl₃) allowed to react with CF₃SO₂Na and a series of indoles afforded the corresponding 3-CF₃S derivatives selectively in good to excellent yields (Scheme 74) [101]. Unlike the work of Cai using PPh₃ and N-chlorophthalimide, here, PCl₃ was used both as a reducing and chlorinating reagent. ¹⁹F NMR investigation of reaction intermediates showed the signal of CF₃SCl, species which was interpreted as the key intermediate in the reaction system. Noteworthy, switching from PCl₃ to P(O)Cl₃ allowed the synthesis of the trifluoromethylsulfinyl derivatives instead of the trifluoromethylsulfenyl ones (see next section).

At the same time, Zhao, Lu and co-workers described similar observations. The trifluoromethylsulfenylation of indoles and electron-rich aromatics was realised with CF₃SO₂Na in the presence of PCl₃ (1.2 instead of 3 equivalents) in acetonitrile at
60 °C (Scheme 75) [102]. The authors proposed a reaction mechanism that involved the 3-trifluoromethylsulfinyl intermediate 88 (Scheme 75). Consequently, a decrease of the amount of PCl₃ and the temperature was proposed to interrupt the reaction and to obtain 88 selectively (see next section).

Aryl iodides served as substrates in a programmable regioselective trifluoromethylsulfinylation by direct coupling with CuSCF₃ generated form CF₃SO₂Na in the presence of copper(I) chloride and triphenylphosphine. Indeed, Yang, Vicic and co-workers described the deoxygenative reduction of CF₃SO₂Na to form the ligand-free CuSCF₃ intermediate that reacted with a diverse array of aryl iodides in high yields (Scheme 76) [103]. In addition, CuSCF₃ was reacted with various ligands to furnish air-stable [LCu(SCF₃)] complexes as trifluoromethylsulfinylating agents.

A few years later, the same group reported the synthesis of the trifluoromethanesulfinamide 89 derived from (1R,2S)-ephedrine using the process described above (Scheme 78). Compound 89 was used as an efficient trifluoromethylating agent for a wide range of non-enolisable and enolisable carbonyl compounds [105].

Other N-aryl- and N-alkyltrifluoromethanesulfinamides have been prepared from the corresponding anilines or aliphatic amines with CF₃SO₂Na and phosphoryl chloride for further reactions with arynes [106] or in the synthesis of trifluoromethylsulfonimidates [107].

Another direct trifluoromethylsulfinylation method was described by Wakselman’s group in 2001 with CF₃SO₂Na in the presence of triflic acid (Scheme 79) [108]. This method was applied to simple aryls featuring a halogen atom, a OCF₃ group or an acetalidilide function. In this reaction, ortho/para regio-
isomers were formed in ratios from 25:75 to 3:97. With regard to the mechanism, the sulfinate was protonated to generate the highly electrophilic \( \text{CF}_3\text{S(OH)}^2^+ \) species that underwent an \( \text{S}^\varepsilon_{\text{Ar}} \) with arenes. A further development of the method consisted in the replacement of triflic acid with triflic anhydride in dichloromethane, and this strategy has been applied to the synthesis of trifluoromethylsulfonium salts, known as Umemoto’s reagents [109-111].

After these initial works, it is only in 2017 that new results using \( \text{CF}_3\text{SO}_2\text{Na} \) appeared in the field. As briefly mentioned in the preceding section, Liu, Lin and co-workers evaluated different phosphorus reductive reagents and found that \( \text{PCl}_3 \) (3 equiv) afforded the corresponding 3-CF\(_3\)S derivatives whereas \( \text{P(O)}\text{Cl}_3 \) (1 equiv) allowed to get selectively the trifluoromethylsulfanyl derivatives 90 (Scheme 80) [101].

With the same objective of partial reduction of \( \text{CF}_3\text{SO}_2\text{Na} \) with phosphorus reagents for the selective trifluoromethylsulfinylation, Zhao, Lu and co-workers noticed that a decrease of the amount of \( \text{PCl}_3 \) and a slight lowering of the temperature were beneficial to the desired trifluoromethylsulfinylation (Scheme 81) [102].

### 4 Trifluoromethylsulfonylation

The trifluoromethylsulfonyl motif (SO\(_2\)CF\(_3\), Tf, triflyl) is highly electron-withdrawing (SO\(_2\)CF\(_3\), \( \sigma_m = 0.79 \), \( \sigma_p = 0.93 \)) and trifluoromethylsulfones (or triflones), in which the trifluoromethylsulfonyl group is attached to a carbon atom, are moderately lipophilic (SO\(_2\)CF\(_3\), \( \pi = 0.55 \) versus CF\(_3\), \( \pi = 0.88 \)). Therefore, the SO\(_2\)CF\(_3\) group has been frequently employed in catalysts and ligands, as subunit of bioactive compounds, or as building block for advanced functional materials. Trifluoromethylsulfones have been prepared by several approaches [5], in particular by means of \( \text{CF}_3\text{SO}_2\text{Na} \) as compiled hereafter.

\[ \text{C}_{\text{sp3}}\text{– SO}_2\text{CF}_3 \] bond-forming reactions

The trifluoromethanesulfinate, triflate anion, possesses a low nucleophilicity thus affecting its potential in substitution reactions. Mainly primary bromides and some secondary ones (\( \alpha \)-bromo ketones and esters) could be converted into trifluoromethylsulfones. From benzyl bromides, phase-transfer conditions [112] and/or high temperatures [113-115] were required to obtain the triflones in low to high yields (Scheme 82). Using benzyl chloride in propionitrile at reflux led to 90% yield of the corresponding triflone [115]. Methyl iodide was also used as substrate for the formation of methyl trifluoromethylsulfone [116]. The displacement of a tosyl group by \( \text{CF}_3\text{SO}_2\text{Na} \) in the presence of \( n\text{-Bu}_4\text{NI} \) in THF worked with 60 % yield [117].
Scheme 83: Formation of α-trifluoromethylsulfonyl ketones, esters, and amides.

Allylic trifluoromethylsulfones could be prepared from aromatic allylic alcohols or esters and CF$_3$SO$_2$Na in the presence of p-toluenesulfonic acid at 100 °C in dioxane. The reaction was highly regioselective, worked well with primary, secondary and tertiary allylic alcohols, and tolerated a wide range of functions (Scheme 84) [120]. The reaction proceeded through an SN$_1$-type mechanism by the formation of a cationic Π-allyl intermediate by means of p-toluenesulfonic acid.

Another example of trifluoromethanesulfonylation of a diaryl iodonium salt was reported by Li and co-workers as a single case, among several other nucleophiles, using 10 mol % of copper(II) triflate in dichloroethane at 80 °C [122]. The hypervalent iodine species could also be generated in situ [123].

In 2016, Shekhar’s group finally succeeded in the trifluoromethanesulfonylation of the more readily available (het)aryl triflates and some aryl chlorides using a combination of Pd$_2$(dba)$_3$ and the bulky RockPhos phosphine ligand in toluene and tris(3,6-dioxaheptyl)amine (TDA) as phase-transfer catalyst to facilitate the reaction with the sparingly soluble CF$_3$SO$_2$Na (Scheme 86) [124].

C$_{sp^2}$–SO$_2$CF$_3$ bond-forming reactions

Aryl triflones: The synthesis of aryl trifluoromethylsulfones was investigated by Shekhar and co-workers in 2013. First, Pd- and Cu-catalysed coupling reactions with iodobenzene or arylboronic acids failed because of the poor nucleophilicity of CF$_3$SO$_2$Na [121]. It was next found that aryl iodonium salts reacted with CF$_3$SO$_2$Na in the presence of copper catalysts. In particular cuprous oxide in DMF gave the triflones in moderate to high yields from a variety of symmetrical and unsymmetrical (het)aryl iodonium salts 91 bearing various functional groups and counteranions (Scheme 85) [121]. The reaction was sulfonyl-retentive and was likely to proceed via a nonradical pathway, probably involving Cu(I)/Cu(III) intermediates.

Arenediazonium tetrafluoroborates 92 were also suitable substrates for the formation of triflones. Xu, Qing and a co-worker demonstrated that CF$_3$SO$_2$Na produced triflones when engaged in a Cu-catalysed reaction in DMSO (Scheme 87) [76]. The reaction was sulfonyl-retentive whereas in the presence of the oxidant tert-butyl hydroperoxide the chemoselective trifluoromethylation was obtained (see Scheme 52).
Vinyl triflones: The synthesis of two vinyl trifluoromethylsulfonyl compounds was reported in 2004 by Ochiai and co-workers by treatment of $\lambda^3$-bromane with CF$_3$SO$_2$Na in DCM at 0 °C (Scheme 89) [126]. The reaction also produced 1-alkynyl triflones as minor products. The 1-alkynyl-$\lambda^3$-bromanes acted as Michael acceptors for the sulfinate anion and underwent tandem Michael addition–carbene insertion reactions to yield the 1-trifluoromethanesulfonylcyclopentenes.

Vinyl triflones with exclusive $E$-selectivity could also be prepared from allylic alcohols and CF$_3$SO$_2$Na under metal-free conditions as reported by Xu, Ji and co-workers (Scheme 90) [127]. Under acidic conditions, the $\pi$-allylic carboxylation reacted with the sulfanyl anion leading to allylsulfone 95, which underwent an electrophilic addition of PIDA and capture of the benzylic carboxylation by water. Then, a concerted proton elimination and C–I bond cleavage occurred to give the triflylated allylic alcohol 94.

Huang, Xu and co-workers demonstrated that styrenes, but also vinylbenzofuran and vinylthiophene, reacted with CF$_3$SO$_2$Na in the presence of iodine and CuCN to afford regioselectively the internal vinyl triflones 96 (Scheme 91) [128]. A cationic reaction mechanism was proposed by electrophilic addition of I$_2$ (or the in situ generated CF$_3$SO$_2$I) to the olefin. The highly strained iodonium bridge subsequently reacted with the sulfanyl anion to afford the iodotriflylated product, which eliminated HI to give the vinyl triflone. The role of CuCN was not precised at this stage.
C$_{6}$$^{sp^{2}}$-SO$_2$CF$_3$ bond-forming reactions
Apart from the side products described in Scheme 89, a variety of acetylenic triflones 98 was proposed by Zhang and co-workers. Alkynyl(phenyl) iodonium tosylates 97 reacted with CF$_3$SO$_2$Na in a transition metal-free protocol to furnish the acetylenic triflones under mild conditions (Scheme 92) [129]. The authors suggested that alkylidene carbene intermediates might be formed followed by a 1,2-rearrangement to yield the triflones. The reaction from ethynylbenzene and CF$_3$SO$_2$Na in the presence of Koser’s reagent allowed to obtain the corresponding triflone albeit in a 33% yield.

S–SO$_2$CF$_3$ and Se–SO$_2$CF$_3$ bond-forming reactions
Langlois’ group prepared thiotrifluoromethanesulfonates 100 from sulfenyl chlorides 99 or disulfides 101 by two methods: first, sulfenyl chlorides were reacted with CF$_3$SO$_2$Na in DCM at room temperature [130]; second, a wider scope was obtained by reaction of disulfides with CF$_3$SO$_2$Na under oxidative conditions with either bromine [130] or PIFA [131] (Scheme 93a). These methodologies were extended to phenylselenyl chloride and diphenyl diselenide (Scheme 93b).

Conclusion
Sodium trifluoromethanesulfinate was used for the first time in direct radical trifluoromethylation under oxidative conditions by the Langlois group in 1991. Since that time its chemistry has evolved sporadically till 2011 and then immensely thanks to Baran’s contribution. It enjoyed a rapid growth not only as donor of the trifluoromethyl group but also as a trifluoromethyl-sulfenylating agent, for the transfer of the whole SCF$_3$ motif, and as trifluoromethanesulfynylating agent for S(O)CF$_3$ transfer. CF$_3$SO$_2$Na is an easy-to-handle, inexpensive reagent that has become versatile for the construction of sophisticated fluorinated products in the pharmaceutical chemistry. It is the authors’ hope that this review will contribute to stimulate further research toward new reactions and applications for this reagent that could include the formation of new bonds with other heteroatoms, novel tandem reactions, and the exploration of asymmetric reactions, so far absent with CF$_3$SO$_2$Na, to cite but a few examples.
