Abstract

We investigate the production and detection prospects for the quintuplet heavy leptons at the LHC in the context of a new model which is proposed as a viable and testable solution to the neutrino mass problem. We classify the signals, carry out a full simulation on the signals and the relevant backgrounds at the 14 TeV LHC. After applying suitable kinematic cuts, the background events are substantially suppressed. The signals of the heavy leptons might be detected at the 14 TeV LHC.

1. INTRODUCTION

The Standard Model (SM) of particle physics has successfully described experimental data so far. The Large Hadron Collider (LHC) discovered a SM-like Higgs particle \[1\] with mass around 125 GeV on July 4, 2012, which might be treated as significant evidence for further proving the SM. However, the SM still has theoretical shortcomings, like small neutrino masses. Many new physics models beyond the SM have been proposed aiming to solve this problem. Three types of seesaw mechanisms can explain the small neutrino masses by introducing extra particles at a high scale, which generates the neutrino masses through the effective dimension-five Weinberg operator \[2\] at tree level. The extra particles correspond to a heavy fermion singlet in type I, a scalar triplet in type II and a fermion triplet in type III, respectively \[3–5\]. Other mechanisms can also account for the small neutrino masses and should be explored.

In addition to the canonical seesaw mechanisms, the cascade seesaw mechanism \[6\] was proposed to generate neutrino masses through a higher dimension \((5 + 4n)\) operator. Similar ideas for generating the neutrino masses via the higher dimensional operators are considered in Refs. \[2, 8\]. The case \(n = 1\) \[9\] corresponds to the minimal version of the cascade seesaw, which will be considered in this paper. In addition to SM particles, this model introduces three generations Majorana quintuplets \(\Sigma_R\) with zero hypercharge transforming as \((1,5,0)\) under the SM gauge group \(SU(3)_C \times SU(2)_L \times U(1)_Y\) and a scalar quadruplet \(\Phi\) transforming as \((1,4,-1)\). In this model, small neutrino mass \(m_\nu \sim \frac{v^6}{\mu_\Phi M_k}\) is obtained via an effective dimension-nine operator \((LLHH)(H^\dagger H)^2\). Here, \(v\) is the vacuum expectation value (vev) of the SM Higgs, \(\mu_\Phi\) is the mass scale of the scalar quadruplet and \(M_k\) is the mass scale of the \(k\) generation fermion quintuplet.\(^1\) This is different from the conventional three types of seesaw formula \(m_\nu \sim v^2/M\), where \(M\) is the scale of the new physics. In this model, neutrino masses can also be generated by a radiative diagram which induce a dimension-five operator with additional loop suppression. This loop mass of neutrino is not achieved in the type III seesaw model. This new model with Majorana quintuplets is therefore something of a hybrid between the traditional seesaw mechanisms and the traditional radiative models of neutrino masses.

\(^1\) Assuming \(\mu_\Phi \sim M_k \sim M\), the neutrino mass is approximately \(m_\nu \sim \frac{v^6}{M^5}\).
The fermion quintuplet contains the doubly charged, singly charged and neutral heavy leptons. The doubly charged heavy leptons are salient feature appearing in many models, which can provide two same-sign leptons as the smoking gun for the scenarios [10]. Any signal for such kind of new leptons in future high energy experiments will play an important role in testing the SM flavor structure and discovery of the new physics. Many studies have been carried out on single production and pair production of the doubly charged lepton [11–15]. In addition, Refs. [16–19] have also studied the phenomenology of doubly charged heavy leptons, singly charged heavy leptons and neutral leptons in exotic lepton multiplet models. The doubly charged fermions also appear in flavor models in warped extra dimensions and in some general models [20–23]. In this paper, we calculate the production of the doubly charged, singly charged and neutral heavy leptons, and analyze the signals and backgrounds at the LHC in the context of this zero hypercharge quintuplet fermion model.

The heavy leptons have been searched at the LHC, which has already posed significant bounds on the masses of these exotic leptons. But such searches depend strongly on the flavor structure. Light states are still allowed if their couplings are suppressed, if they decay into final states affected by large backgrounds, or if they are not efficiently produced at the LHC. Reference [24] has given that the current lower bound for the mass of a generic charged lepton is 100.8 GeV. The ATLAS and CMS collaborations have recently provided lower bounds on the mass of long lived multi-charged particles, which decay outside the detector [25, 26]. These constraints don’t apply to promptly decaying particles like those that we consider here. The stronger bounds on the masses of the exotic leptons are provided from the generic searches for lepton-rich final states at 8 TeV [27, 28]. These constraints will be considered when we discuss the mass range of the signals in the following analysis.

The rest of the paper is organized as follows. In Sec.II, we review the basic content of the new model. In Sec.III, we calculate the cross sections of the heavy leptons and present the phenomenological analysis for several interesting search channels. Our main results are recapitulated in Sec.IV.

2. THE MODEL WITH MAJORANA QUINTUPLETS

Recently, Ref. [9] proposed an alternative model to address neutrino mass problem.
This model is based on the SM gauge symmetry $SU(3)_C \otimes SU(2)_L \otimes U(1)_Y$. In addition to the SM particles, three generations of Majorana quintuplets $\Sigma_R = (\Sigma_{R+}, \Sigma_{R0}, \Sigma_{R-}, \Sigma_{R-R})$ with zero hypercharge are introduced transforming as (1,5,0) under the SM gauge group, where $R$ denotes the chirality. The fermionic quintuplet with zero hypercharge is treated as the simplest generation of type III seesaw Majorana triplet to a higher isospin multiplet. It can also provide a viable minimal dark matter candidate \cite{29}. In addition to the SM Higgs doublet $H = (H^+, H^0)$, a scalar quadruplet $\Phi = (\Phi^+, \Phi^0, \Phi^{-}, \Phi^{--}) \sim (1,4,-1)$ is introduced, its neutral member $\Phi^0$ acquires a nonvanishing vev and generates neutrino masses. The masses of the new particles predicted in this model are naturally at the TeV scale.

The gauge invariant and renormalizable Lagrangian involving $\Sigma_R$ and $\Phi$ can be given as \cite{9}:

$$
\mathcal{L} = \sum R i \gamma^\mu D_\mu \Sigma_R + (D^\mu \Phi)\dagger (D_\mu \Phi) - (\overline{L}_L Y \Phi \Sigma_R + \frac{1}{2} (\Sigma_R)^C M \Sigma_R + H.c.) - V(H, \Phi),
$$

where the $\overline{L}_L Y \Phi \Sigma_R$ term is the Yukawa coupling among the scalar quadruplet, the SM left-hand lepton doublet and the fermion quintuplet, and $Y$ is the Yukawa-coupling matrix. The $\frac{1}{2} (\Sigma_R)^C M \Sigma_R$ term is the Majorana mass term of the fermion quintuplet, $M$ is the mass matrix of the heavy leptons. The $V(H, \Phi)$ term is the scalar potential, whose expression can be given as follows \cite{9}:

$$
V(H, \Phi) = -\mu_H^2 H\dagger H + \mu_\Phi^2 \Phi\dagger \Phi + \lambda_1 (H\dagger H)^2 + \lambda_2 H\dagger H \Phi\dagger \Phi + \lambda_3 H^* H \Phi^* \Phi \\
+ (\lambda_4 H^* H \Phi + H.c.) + (\lambda_5 H H \Phi\dagger + H.c.) + (\lambda_6 H \Phi^* \Phi + H.c.) \\
+ \lambda_7 (\Phi\dagger \Phi)^2 + \lambda_8 \Phi^* \Phi \Phi^* \Phi.
$$

The neutral components of the Higgs doublet and scalar quadruplet $H^0$, $\Phi^0$ are all responsible for the electroweak symmetry breaking. The vev’s of these neutral scalar fields are $v$ and $v_\Phi$. There are

$$
v = 174\text{GeV}, \quad v_\Phi \simeq -\frac{1}{\sqrt{3}} \frac{\lambda_1 v^3}{\mu_\Phi^2}.
$$

$v_\Phi$ will contribute the mass corrections of $M_Z$ and $M_W$, it will confront the constraints from $\rho$ parameter. The contribution of the model to $\rho$ parameter expression is $6 v_\Phi^2 / v^2$.  

We take the $\rho$ parameter measurement $\rho = 1.0004^{+0.0003}_{-0.0004}$ reported by the Particle Data Group to get $v_\Phi$ limit, $v_\Phi \lesssim 1.9$ GeV.

The Majorana mass matrix of the light neutrino induced from diagonalizing the neutral lepton masses is given by

$$m^\text{tree}_\nu = -\frac{1}{2} v_\Phi^2 Y M^{-1} Y^T. \quad (4)$$

In the basis where the matrix of heavy leptons is real and diagonal, $M = \text{diag}(M_1, M_2, M_3)$, and utilizing the expression in Eq.(3), we can get the tree-level neutrino mass expression which corresponds to the dimension-nine seesaw operator

$$(m_\nu)^\text{tree}_{ij} = -\frac{1}{6} (\lambda_4^*)^2 \frac{v^6}{\mu^4} \sum_k \frac{Y_{ik}Y_{jk} M_k}{M_k}. \quad (5)$$

In addition to the tree-level neutrino mass, the neutrino mass can also be generated at one-loop level, which has the following form

$$(m_\nu)^\text{loop}_{ij} = -\frac{5}{24} \frac{\lambda_5^* v^2}{\pi^2} \sum_k \frac{Y_{ik}Y_{jk} M_k}{m^2_{\Phi} - M_k^2} [1 - \frac{M_k^2}{m^2_{\Phi} - M_k^2} \ln \frac{m^2_{\Phi}}{M_k^2}]. \quad (6)$$

In the case of $m^2_{\Phi} \simeq M_k^2$, the neutrino mass induced at one loop can be approximately expressed as

$$(m_\nu)^\text{loop}_{ij} = -\frac{5}{48} \frac{\lambda_5^* v^2}{\pi^2} \sum_k \frac{Y_{ik}Y_{jk}}{M_k}. \quad (7)$$

If we consider the tree-level and loop-level contributions together, the neutrino mass is given by

$$(m_\nu)_{ij} = (m_\nu)^\text{tree}_{ij} + (m_\nu)^\text{loop}_{ij}$$

$$= -\frac{1}{6} (\lambda_4^*)^2 \frac{v^6}{\mu^4} \sum_k \frac{Y_{ik}Y_{jk} M_k}{M_k} + \frac{5}{24} \frac{\lambda_5^* v^2}{\pi^2} \sum_k \frac{Y_{ik}Y_{jk} M_k}{m^2_{\Phi} - M_k^2} [1 - \frac{M_k^2}{m^2_{\Phi} - M_k^2} \ln \frac{m^2_{\Phi}}{M_k^2}]. \quad (8)$$

Both the heavy leptons ($\Sigma^0, \Sigma^\pm, \Sigma^{\pm\pm}$) and the scalars ($\Phi^0, \Phi^\pm, \Phi^{--}$) can couple to the SM particles in the new model. However, we don’t consider the phenomenology of the quadruplet scalars in this paper. We only give the Feynman rules of the heavy leptons to the SM particles, which are related to our calculation, can be written as
\begin{align}
\Sigma^0lW : & \ -\frac{e}{S_W} V_{l\Sigma} \gamma^\mu P_L,
\Sigma^0\nu Z : & \ \frac{1}{\sqrt{2}} \left( \frac{e}{S_W C_W} V_{l\Sigma}^\dagger \gamma^\mu P_L - V_{PMNS}^{T} V_{l\Sigma}^* \gamma^\mu P_R \right),
\Sigma^+lZ : & \ \frac{\sqrt{3}}{4} \frac{e}{S_W C_W} V_{l\Sigma}^* \gamma^\mu P_R,
\Sigma^{++}lW : & \ \frac{3}{2} \frac{e}{S_W} V_{l\Sigma}^* \gamma^\mu P_R,
\end{align}

where $S_W = \sin \theta_W$, $C_W = \cos \theta_W$, $\theta_W$ is the Weinberg angle, and $V_{PMNS}$ is the $3 \times 3$ Pontecorvo-Maki-Nakagata-Saki (PMNS) matrix \[31\]. $P_L(P_R)$ is the left-hand (right-hand) projection operator. $V_{l\Sigma}$ describes the mixing of the heavy leptons and the SM leptons, its expression is given by

$$V_{l\Sigma} = (v_\Phi Y M^{-1})_{l\Sigma}. \quad (10)$$

This variable is proportional to $\sqrt{m_\nu/M_{\Sigma}}$ which can reach $10^{-7}$ when we take neutrino mass $m_\nu \sim 0.1$ eV \[30\] and set the parameters as $Y \sim 10^{-3}$, $\lambda_4 \sim 10^{-2}$ and $\lambda_5 \sim 10^{-4}$ \[8\].

3. PHENOMENOLOGY OF THE QUINTUPTLET LEPTONS AT THE LHC

In this section, we will discuss the phenomenology of the heavy leptons at the LHC. The productions of the heavy leptons are dominated via the Drell-Yan process mediated by the SM gauge bosons $\gamma$, $Z$ and $W$. The effective cross sections $\sigma(s)$ can be evaluated from $\hat{\sigma}(\hat{s})$ by convoluting with $f_{q_1/p}(x_1)$ and $f_{q_2/p}(x_2)$,

$$\sigma(s) = \int_{x_{\text{min}}}^{1} dx_1 \int_{x_{\text{min}}/x_1}^{1} dx_2 f_{q_1/p}(x_1) f_{q_2/p}(x_2) \hat{\sigma}(\hat{s}), \quad (11)$$

where $\hat{s} = x_1 x_2 s$ is the effective center-of-mass (c. m.) energy squareD for the partonic process, and $x_{\text{min}} = 4M_{\Sigma}^2 / s$. For the quark distribution functions $f_{q_1/p}(x_1)$ and $f_{q_2/p}(x_2)$, we will use the form given by the leading order parton distribution function CTEQ6L1 \[32\]. The cross sections have been calculated using tree-level matrix elements generated by MadGraph package \[33\]. The SM parameters are taken as $M_W = 80.4$ GeV, $M_Z = 91.2$ GeV and $S_W^2 = 0.231$ \[34\]. In Fig.1, we show the production cross sections versus the heavy lepton mass $M_{\Sigma}$ at the 8 (14) TeV LHC. It is obvious that all the cross sections
decrease with the increase of the heavy lepton mass $M_\Sigma$. The cross section of $\Sigma^{++}\Sigma^{--}$ production is the largest which can reach 2976 fb for $M_\Sigma = 300$ GeV and the c. m. energy $\sqrt{s} = 14$ TeV. The $\Sigma^+\Sigma^-$ production has the smallest cross section, for $200$ GeV $\leq M_\Sigma \leq 1000$ GeV, its value is in the range of $744$ fb $\sim 0.6$ fb at the 14 TeV LHC. In the following, we will focus on their signals and backgrounds at the LHC.

FIG. 1: The cross sections of the heavy lepton pair or associated productions as a function of the mass $M_\Sigma$ for the c.m. energy $\sqrt{s} = 8$ TeV and 14 TeV.

To discuss the signatures of the heavy quintuplet leptons, one needs to understand their decay properties to the SM particles. For the most characteristic particle in the model, the doubly charged heavy lepton $\Sigma^{\pm\pm}$ can only decay to a SM charged lepton with a same-sign $W$ boson $\Sigma^{\pm\pm} \rightarrow l^\pm W^\mp$. As for $\Sigma^0$, it can decay to $l^\pm W^\mp$ and $\nu Z$. And $\Sigma^\pm$ can decay to $l^\pm Z$ and $\nu W^\mp$. The decay widths sum over the three generations.
of leptons. The detailed formulas for all of these decay channels are listed in Ref. [9]. There are small mass differences between two components of Σ quintuplet induced by loops of SM gauge bosons, which are far smaller than the mass scale of Σ. For $M_{\Sigma} = 400$ GeV, the mass differences are $M_{\Sigma^{++}} - M_{\Sigma^+} \approx 490$ MeV and $M_{\Sigma^+} - M_{\Sigma^0} \approx 163$ MeV, this will induce additional decay channel, such as $\Sigma^i \rightarrow \Sigma^j \pi^+$. However, these decays are suppressed by narrow phase space. Thus, we take $M_{\Sigma^{++}} \approx M_{\Sigma^+} \approx M_{\Sigma^0}$ in the following. The branching widths and the total width of the heavy leptons are proportional to the square of the mixing matrix $|V_{l\Sigma}|^2$. In addition, $V_{l\Sigma}$ affects the reconstructed distribution of the signal events. From the experimental point of view, the mixing matrix $V_{l\Sigma}$ decides the contributions to the lepton flavor violating (LFV) processes. Thus, the experimental upper bounds on the branching ratios (BRs) of the radiative LFV decays, for instance, BR($\mu \rightarrow e\gamma$) $< 5.7 \times 10^{-13}$ [35] and BR($\mu \rightarrow 3e$) $< 1.0 \times 10^{-12}$ [36] can give constraints on $V_{l\Sigma}$. We take typical value $V_{l\Sigma} = 3.5 \times 10^{-7}$ in this paper. Due to the multiple decay modes of the heavy leptons and the SM gauge bosons, we classify the signals in terms of the charged lepton multiplicity as following. And then we consider two typical cases, $M_{\Sigma} = 300$ GeV and 500 GeV, to perform a full simulation at the 14 TeV LHC.

In order to simulate the unweighted events more realistically at the parton level, we smear the energies of the final state lepton and jets according to the assumption of the Gaussian resolution parametrization

$$\frac{\delta(E)}{E} = \frac{a}{\sqrt{E}} \oplus b, \quad (12)$$

where $\frac{\delta(E)}{E}$ is the energy resolution, $a$ is a sampling term, $b$ is a constant term, and $\oplus$ denotes a sum in quadrature. We take $a = 5\%$, $b = 0.55\%$ for leptons and $a = 100\%$, $b = 5\%$ for jets [37].

The following basic selection cuts are applied to all of the signal and background events while generating events in MadGraph,

$$p_T^l > 15 \text{GeV}, \quad |\eta_l| < 2.5, \quad E_T > 25 \text{GeV}$$
$$p_T^j > 20 \text{GeV}, \quad |\eta_j| < 2.5,$$
$$\Delta R_{ll} > 0.3, \quad \Delta R_{jl} > 0.4, \quad \Delta R_{jj} > 0.4, \quad (13)$$

where $p_T$ denotes the transverse momentum, $E_T$ is the missing transverse momentum from the invisible neutrino in the final states, $\Delta R_{ij}$ is defined as $\Delta R_{ij} = \sqrt{(\Delta \eta_{i,j})^2 + (\Delta \phi_{i,j})^2}$,
where $\Delta \eta$ is the rapidity gap and $\Delta \phi$ is the azimuthal angle gap between the particle pair $(i, j = l, j)$. For the SM leptons, we only consider an electron and a muon in signal simulation and take the lepton-tagging efficiency $\epsilon_l = 90\%$. The light jet $j$ means light quarks or gluons. After the basic cuts, we further employ optimized kinematical cuts according to the kinematical differences between the signal and backgrounds to reduce the background to a controlled level.

1. The $2l^\pm l'^\mp 2jE_T$ signal

Pair production is the main channel of the doubly charged heavy leptons. Two opposite sign $W$ bosons and two opposite sign leptons are generated by the two heavy leptons $\Sigma^{++}$ and $\Sigma^{--}$ decaying. We demand that one of the $W$ bosons decays leptonically and the other one decays hadronically. So the final states contain two leptons with same charge, one lepton with opposite charge, two light jets plus one neutrino,

$$pp \to \Sigma^{--} \Sigma^{++} \to l^- W^- l^+ W^+ \to l^- l^+ jj l^+\nu(l^- \bar{\nu}), \quad (14)$$

The measurement accuracy of the hadronic calorimeter is not enough to distinguish the $W$ or $Z$ boson. Thereby, the production of the singly charged heavy lepton in association with the doubly charged heavy lepton also contributes to the above signal. We demand that the $Z$ boson decays to two light jets with BR$\sim70\%$ and the $W$ boson decays leptonically with BR$\sim21\%$.

$$pp \to \Sigma^{\pm\pm} \Sigma^{\mp} \to l^\pm W^\pm l'^\mp Z \to l^\pm l'^\mp jj l^+\nu(l^- \bar{\nu}). \quad (15)$$

Although the production cross section of this channel is smaller than that of the doubly charged heavy lepton pair production channel, it plays a role in increasing the signal rate. The $2l^\pm l'^\mp 2jE_T$ signal comes from both of the processes $pp \to \Sigma^{--} \Sigma^{++}$ and $pp \to \Sigma^{\pm\pm} \Sigma^{\mp}$. The heavy leptons take the same mass as previously described, therefore, we can reconstruct the heavy lepton masses for these two channels in the same mass range. The corresponding backgrounds are $l^+ l^- 2jW^\pm$ and $W^+ W^- 2jW^\pm$ where $W$ decays leptonically.

The two jets in the signal events come from $W/Z$ boson decay, however, the jets in the backgrounds mainly come from QCD radiation. In order to reduce the background
As discussing above, there are three SM leptons in the final states. The lepton which has the largest transverse momentum is defined as the leading lepton (lepton1), it comes from the heavy lepton decay in the signal. Its $p_T$ spectrum peaks at around half of the heavy lepton mass while the lepton in the background tends to be soft. We order the leptons by their values of $p_T$ for the signal and backgrounds, and display the normalized $p_T$ distribution of the leading lepton (lepton1) for the $2l^±l^±2jE_T$ signal and background events in Fig.2. For the leading lepton (lepton1), we can see that the signal distribution (the red solid line) peaks at around 150 (250) GeV for the heavy lepton mass $M_Σ=300$ (500) GeV while the $lljjW$ (green dashed line) and $WWjjW$ (the blue dotted line) background distributions peak at around 80 GeV. We can distinguish between the signal and the backgrounds by a cut based on the kinematical variable $p_T$ of the leading lepton (lepton1) as follows,

$$p_T(\text{lepton1}) > 100(160)\text{GeV},$$

where the cut $p_T(\text{lepton1}) > 100$ GeV corresponds to $M_Σ=300$ GeV and the value in

FIG. 2: Normalized $p_T$ distribution of the leading lepton in the $2l^±l^±2jE_T$ signal for $M_Σ=300$ GeV (a) and 500 GeV (b) at the 14 TeV LHC.
FIG. 3: Normalized invariant mass distribution of $M(ll\nu)$ and $M(ljj)$ in the $2l^{\pm}l^{'\mp}2jE_T$ signal for $M_{\Sigma}=300$ GeV (a,b) and 500 GeV (c,d) at the 14 TeV LHC.

parenthesis is the case for $M_{\Sigma}=500$ GeV. The cuts are very effective in reducing the backgrounds and preserving the signal events.

We subsequently reconstruct the masses of the heavy leptons to further suppress the backgrounds. The two jets with one charged lepton in the final states can reconstruct one heavy lepton mass $M(ljj)$, and the remaining two charged leptons and one neutrino can reconstruct another heavy lepton mass $M(ll\nu)$. The normalized invariant mass distribu-
Table I: The cross sections (fb) and the event numbers of the signal \(2l^\pm l^\mp 2jE_T\) and the backgrounds \(l^+l^-2jW^\pm\) and \(W^+W^-2jW^\pm\) for \(M_\Sigma=300\) (500) GeV at the 14 TeV LHC with \(\mathcal{L}=10\) fb\(^{-1}\).

| Condition                  | Signal \(2l^\pm l^\mp 2jE_T\) | Bkg \(l^+l^-2jW^\pm\) | Bkg \(W^+W^-2jW^\pm\) |
|----------------------------|-------------------------------|-------------------------|-------------------------|
| Basic cuts                 | 28.92 (4.14)                  | 56.91                   | 0.308                   |
| \(60\text{GeV}< M_{jj}<110\text{GeV}\) | 27.81 (4.03)                  | 12.72                   | 0.058                   |
| \(p_T(l_1)>100\text{(160)}\text{GeV}\) | 26.41 (3.89)                  | 4.63 (1.62)             | 0.031 (0.015)           |
| \(|M_{ll\nu}-M_{ljj}|<30\text{(50)}\text{GeV}\) | 22.44 (3.56)                  | 0.42 (0.36)             | 0.005 (0.003)           |
| Number of events           | 224.4 (35.6)                  | 4.2 (3.6)               | 0.05 (0.03)             |
| \(S/\sqrt{S+B}\)          | 14.84 (5.68)                  |                         |                         |

We define the statistical significance as \(s = \frac{S}{\sqrt{S+B}}\) where \(S\) and \(B\) denote the number of signal and background events, respectively. It can reach 14.84 (5.68) for \(M_\Sigma=300\) (500) GeV at the 14 TeV LHC with an integrated luminosity of 10 fb\(^{-1}\). In order to illustrate the needed integrated luminosity at LHC to reach a given statistical significance, we plot the integrated luminosity versus the heavy lepton mass for \(3\sigma\) and \(5\sigma\) statistical significances for the \(2l^\pm l^\mp 2jE_T\) signal at the 14 TeV LHC in Fig.4. As is shown in Fig.4., this signal can be detected at the 14 TeV LHC under the designed integrated luminosity in most mass ranges of the heavy lepton. For \(M_\Sigma=500\) (700) GeV,
FIG. 4: The needed luminosity to observe different masses of the heavy leptons via the $2l^\pm l^\mp 2j E_T$ signal for $3\sigma$ and $5\sigma$ statistical significances at the 14 TeV LHC.

the $5\sigma$ significance requires 7.74 (56.32) fb$^{-1}$.

2. The $2l^\pm 2l^\mp 2j$ signal

The production of the singly charged heavy leptons in association with the doubly charged heavy leptons $\Sigma^{\pm\pm}\Sigma^\mp$ can provide a distinct signal in a case where $W$ decays hadronically and $Z \rightarrow l^+l^-$. Thus, there are two positively charged leptons, two negatively charged leptons plus two jets in the final states,

$$pp \rightarrow \Sigma^{\pm\pm}\Sigma^\mp \rightarrow l^\pm W^\pm l^\mp Z \rightarrow l^\pm l^\pm l^\mp l^\mp jj.$$  \hspace{1cm} (19)

Another two channels also contribute to the signal. For the pair production channel $\Sigma^\pm\Sigma^\mp$, one of the $Z$ bosons decays hadronically and another decays to $l^+l^-$. The decay modes of $W$ and $Z$ in $\Sigma^{\pm\pm}\Sigma^0$ production are consistent with $\Sigma^{\pm\pm}\Sigma^\mp$ production mentioned above,

$$pp \rightarrow \Sigma^{\pm\pm}\Sigma^\mp \rightarrow l^\pm Zl^\mp Z \rightarrow l^\pm l^\pm l^\mp l^\mp jj.$$  \hspace{1cm} (20)
FIG. 5: Normalized $p_T$ distribution of the leading lepton in the $2l^\pm 2j^\mp$ signal for $M_\Sigma = 300 \text{ GeV}$ (a) and 500 GeV (b) at the 14 TeV LHC.

$$pp \to \Sigma^\pm \Sigma^0 \to l^\pm Zl^{\mp}W^{\pm} \to l^\pm l^{\pm}l^{\mp}l^{\mp}jj.$$  \hspace{1cm} (21)

The corresponding backgrounds are $l^+l^-2jZ$ and $t\bar{t}Z$, where $Z \to l^+l^-$ and $t \to bl^+\nu$ ($\bar{t} \to \bar{b}l^-\bar{\nu}$). As there is no neutrino in the signal but there are neutrinos in the backgrounds, we apply a veto cut about the missing transverse momentum $E_T < 25 \text{ GeV}$ replacing that in the basic cuts to reduce the $t\bar{t}Z$ events. We also require the invariant mass of the two jets to peak at the $W/Z$ mass within a mass window of 20 GeV. This cut can rapidly reduce the background while affecting the signal slightly,

$$M_W - 20 \text{GeV} < M(jj) < M_Z + 20 \text{GeV}.$$ \hspace{1cm} (22)

We also plot the normalized $p_T$ distribution of the leading lepton (lepton2) for the $2l^\pm 2j$ signal and background events for $M_\Sigma = 300 \text{ GeV}$ and 500 GeV in Fig.5. The same cuts based on the transverse momentum $p_T$ as mentioned in the $2l^\pm l^\mp j E_T$ signal are applied to suppress the backgrounds and strengthen the signal,

$$p_T(\text{lepton2}) > 100(160) \text{GeV}.$$ \hspace{1cm} (23)
FIG. 6: Normalized invariant mass distribution of $M(lll)$ and $M(ljj)$ in the $2l^\pm l^\mp 2 j_E T$ signal for $M_\Sigma = 300$ GeV (a,b) and 500 GeV (c,d) at the 14 TeV LHC.

One can reconstruct the mass of one heavy lepton via three light leptons, and the other one via the remnant lepton and the two jets. We plot the normalized invariant mass of the two heavy leptons $M(lll)$ and $M(ljj)$ in Fig. 6. In order to further suppress the background to manageable levels, the same invariant mass cuts as were used for the $2l^\pm l^\mp 2 j_E T$ signal are applied to the signal and the backgrounds,

$$|M(lll) - M(ljj)| < 30(50) \text{GeV}. \quad (24)$$
The cross sections (fb) and the event numbers of the signal $2l^\pm 2l^\mp 2j$ and the backgrounds $l^+l^-2jZ$ and $t\bar{t}Z$ for $M_\Sigma = 300$ (500) GeV at the 14 TeV LHC with $L=100\text{ fb}^{-1}$. We summarize the results in Table II. The cross section of $t\bar{t}Z$ is too small for $M_\Sigma = 500$ GeV, we consider that it is approximately zero. The cross sections of the backgrounds are tiny compared to the signal after sequential cuts, and the statistical significance $s$ can reach 5.17 (1.87) at the 14 TeV LHC with an integrated luminosity of

| Condition                                | Signal $2l^\pm 2l^\mp 2j$ | Bkg $l^+l^-2jZ$ | Bkg $t\bar{t}Z$ |

**FIG. 7:** The needed luminosity to observe different mass quintuplet leptons via the $2l^\pm 2l^\mp 2j$ signal for the $3\sigma$ and $5\sigma$ statistical significances at the 14 TeV LHC.
100 fb$^{-1}$. We also give the integrated luminosity versus the heavy lepton mass for 3σ and 5σ statistical significance for the $2l^{\pm}2l^{\mp}2j$ signal at the 14 TeV LHC in Fig.7. If we want to observe this signal for a 5σ statistical significances at $M_\Sigma = 300$ (500) GeV, the integrated luminosities must be larger than 81.797 (706.236) fb$^{-1}$ at 14 TeV LHC. For $M_\Sigma > 700$ GeV, detecting this signal at 5σ requires an integrated luminosity larger than $10^4$, which outreaches the designed luminosity.

3. The $3l^{\pm}l^{\mp}2j$, $3l^{\pm}2l^{\mp}E_T$ and $3l^{\pm}3l^{\mp}$ signals

The lepton-number violating (LNV) processes have a clean SM background and they are easily detected in the experiments [10]. In this paper, LNV like-sign dilepton events are mediated by the exotic heavy lepton decays and are reminiscent of those found in related canonical seesaw models like the type III seesaw [38]. They all predict the $l^+l^-W^\pm Z$ events. We can get the $3l^{\pm}l^{\mp}2j$ signal after the $W$ and $Z$ boson decays, which resemble the $2l^2l^2jj$ signal.

$$pp \to \Sigma^{\pm} \Sigma^0 \to l^\pm Z l^\mp W^\mp \to l^\pm l^\pm l^\mp l^\mp jj.$$  \hspace{1cm} (25)

It is obvious that the leptons with opposite charge can be distinguished in the experiments. Thus, this channel provides a different signal for observing the heavy leptons compared to $2l^2l^2jj$ signal. $W^\mp W^\pm Zjj$ is treated as the background in which $W$ decays leptonically and $Z \to l^+l^-$. The cross section of the background is much smaller than that of the signal, we only apply the basic cuts on the signal and the background. All of the results are listed in Table III.

We also consider the $3l^\pm 2l^{\mp}E_T$ signal which is generated by $\Sigma^{\pm} \Sigma^\mp$ and $\Sigma^{\pm} \Sigma^0$ productions,

$$pp \to \Sigma^{\pm} \Sigma^\mp \to l^\pm W^\pm l^{\mp} Z \to l^\pm l^\pm l^\mp l^{\mp} \nu(\bar{\nu}),$$  \hspace{1cm} (26)

$$pp \to \Sigma^{\pm} \Sigma^0 \to l^\pm Z l^{\mp} W^\pm (l^\pm Z l^{\mp} W^\mp) \to l^\pm l^\pm l^\mp l^{\mp} \nu(\bar{\nu}),$$  \hspace{1cm} (27)

$$pp \to \Sigma^{\pm} \Sigma^0 \to l^\pm Z Z \nu \to l^\pm l^\pm l^\mp l^{\mp} \nu.$$  \hspace{1cm} (28)
where the \( l^\pm Zl^\pm W^\mp \) and \( l^- ZZ\nu \) events are all from the LNV heavy lepton decays and the subsequent leptonic \( Z/W \) decay. The relevant background is \( ZZW^\pm \). The production cross section of the signal is large enough compared to the small background, which is similar to the \( 3l^\pm l^\mp 2j \) signal. All of the results that apply to the basic cuts are displayed in Table III. We also calculate the needed integrated luminosity to observe different mass quintuplet leptons via the \( 3l^\pm l^\mp 2j \) and \( 3l^\pm 2l^\mp E_T \) signals at the 14 TeV LHC in Fig.8.

For \( M_\Sigma = 300 \) (500) GeV, the 5\( \sigma \) significance requires 139.2 (1009.1) fb\(^{-1}\).

|                  | Signal 3l\( ^\pm l^\mp 2j \) | Bkg W\( ^\pm W^\pm Z2j \) | \( S/\sqrt{S+B} \) |
|------------------|-------------------------------|---------------------------|-----------------|
| Basic cuts       | 0.208 (3.01 \times 10^{-2})   | 1.09 \times 10^{-3}       | –               |
| Number of events | 20.8 (3.01)                   | 0.11                      | 4.54 (1.70)     |

|                  | Signal 3l\( ^\pm 2l^\mp E_T \) | Bkg ZZW\( ^\pm \) | \( S/\sqrt{S+B} \) |
|------------------|---------------------------------|----------------|-----------------|
| Basic cuts       | 0.184 (2.41 \times 10^{-2})     | 4.51 \times 10^{-3} | –               |
| Number of events | 18.4 (2.41)                     | 0.45           | 4.24 (1.43)     |

TABLE III: The cross sections (fb) and the event numbers of the signals \( 3l^\pm l^\mp 2j \), \( 3l^\pm 2l^\mp E_T \) and the SM backgrounds for \( M_\Sigma = 300 \) (500) GeV at the 14 TeV LHC with \( \mathcal{L} = 100 \) fb\(^{-1}\).

FIG. 8: The needed luminosity to observe different mass quintuplet leptons via \( 3l^\pm l^\mp 2j \) (left panel) and \( 3l^\pm 2l^\mp E_T \) (right panel) signals for 3\( \sigma \) and 5\( \sigma \) statistical significances at the 14 TeV LHC.
The last signal considered is a clean channel which consists of six leptons in the final states,

\[ pp \rightarrow \Sigma^\pm \Sigma^\mp \rightarrow l^\pm Z l^\mp Z \rightarrow l^\pm l^\pm l^\mp l^\mp l^\mp l^\mp. \] (29)

The corresponding background is \( ZZ Z \), where the \( Z \) also decays to lepton pair. However, the cross section of the signal is so small that it might hardly be detected in the future. Thus, we do not show the relevant numerical results in Table III.

4. CONCLUSIONS AND DISCUSSIONS

The model [9] which is studied in this paper can explain the smallness of the neutrino masses. The empirical masses of the neutrinos \( m_\nu \sim 10^{-1} \) eV can be achieved by Majorana quintuplets \( \Sigma_R \) and scalar quadruplet \( \Phi \) which transform as (1,5,0) and (1,4,-1) under the SM gauge group, respectively. The quintuplet heavy leptons can couple to the SM particles, the couplings are proportional to the mixing matrix \( V_l \Sigma \) between the heavy leptons and the SM leptons. The LHC can provide enough energy and high luminosity to produce such heavy leptons and detect their signatures.

In this paper, we investigated pair production and the associated production of the heavy leptons and found that they are copiously produced by the quark-antiquark annihilation mediated by the neutral and charged SM gauge bosons. Considering the multiple decay modes of the heavy leptons and the SM gauge bosons, we studied several types of signals with different BRs. Firstly, we carried out a full simulation for the signals \( 2l^\pm l^\mp 2j E_T, \ 2l^\pm 2l^\mp 2j \) and the relevant SM backgrounds. The results revealed that the two signals have a large statistical significance. Furthermore, we also studied the LNV signals \( 3l^\pm l^\mp 2j \) and \( 3l^\pm 2l^\mp E_T \). The cross sections of the backgrounds are smaller than those of the LNV signals, thus, we only applied the basic cuts on the signal and background events. For the \( 3l^\pm 3l^\mp \) signal, there were few signal events with high integrated luminosity. Based on the above results, the possible signatures of the heavy leptons could be detected at the 14TeV LHC in the near future.

These production channels could also provide a lepton flavor violating signal at the LHC, where the two leptons from the heavy leptons decay are a electron and a muon, and the \( W \) and the \( Z \) from the heavy lepton decays hadronically so that the signal has a large BR. The signal can be \( e^- \mu^+ 4j \) and the SM background will be dominated by \( W^+ W^- 4j \).
The important difference between signal and background is that the background contains missing energy in the form of neutrinos. Detailed studies, including sample selection and standard cuts, will be presented in the future.

Reference [11] has studied the phenomenology of a lepton triplet in both low energy experiments and at the LHC. There are some differences between the triplet leptons and the quintuplet leptons that we studied here. First of all, Ref. [11] predicted the heavy leptons in the form of a vector-like triplet with hypercharge $\pm 1$. Three generations of fermion quintuplets with zero hypercharge were predicted in the model here and they only have only a right-hand component. Second, the heavy leptons have different couplings with gauge bosons in the two cases. Thus, they have different production cross sections at the LHC. With the different BRs, we can get different signal rates. Third, the quintuplet leptons can produce the LNV signals $3l^\pm l^\mp 2j$ and $3l^\pm 2l^\mp E_T$ which are the key features of the model. In addition, we applied different basic cuts and chose different simulation methods according to the kinematical differences between the signals and the backgrounds to extrude the signals and suppress the backgrounds in our simulation.
