A cardinal number connected to the solvability of systems of difference equations in a given function class

Márton Elekes* and Miklós Laczkovich†

September 23, 2011

Abstract

Let $\mathbb{R}^\mathbb{R}$ denote the set of real valued functions defined on the real line. A map $D : \mathbb{R}^\mathbb{R} \to \mathbb{R}^\mathbb{R}$ is said to be a difference operator, if there are real numbers $a_i, b_i$ ($i = 1, \ldots, n$) such that $(Df)(x) = \sum_{i=1}^{n} a_i f(x + b_i)$ for every $f \in \mathbb{R}^\mathbb{R}$ and $x \in \mathbb{R}$. By a system of difference equations we mean a set of equations $S = \{D_i f = g_i : i \in I\}$, where $I$ is an arbitrary set of indices, $D_i$ is a difference operator and $g_i$ is a given function for every $i \in I$, and $f$ is the unknown function. One can prove that a system $S$ is solvable if and only if every finite subsystem of $S$ is solvable. However, if we look for solutions belonging to a given class of functions, then the analogous statement is no longer true. For example, there exists a system $S$ such that every finite subsystem of $S$ has a solution which is a trigonometric polynomial, but $S$ has no such solution; moreover, $S$ has no measurable solutions.

This phenomenon motivates the following definition. Let $\mathcal{F}$ be a class of functions. The solvability cardinal $\text{sc}(\mathcal{F})$ of $\mathcal{F}$ is the smallest cardinal number $\kappa$ such that whenever $S$ is a system of difference equations and each subsystem of $S$ of cardinality less than $\kappa$ has a solution in $\mathcal{F}$, then $S$ itself has a solution in $\mathcal{F}$. In this paper we will determine the solvability cardinals of most function classes that occur in analysis. As it turns out, the behaviour of $\text{sc}(\mathcal{F})$ is rather erratic. For example, $\text{sc}(\text{polynomials}) = 3$ but $\text{sc}(\text{trigonometric polynomials}) = \omega_1$, $\text{sc}(\{f : f \text{ is continuous}\}) = \omega_1$ but $\text{sc}(\{f : f \text{ is Darboux}\}) = (2^{\omega_1})^+$, and $\text{sc}(\mathbb{R}^\mathbb{R}) = \omega$. We consistently determine the solvability cardinals of the classes of Borel, Lebesgue and Baire measurable functions, and give some partial answers for the Baire class 1 and Baire class $\alpha$ functions.

Key Words: systems of difference equations, cardinal invariants
1 Preliminaries

Difference operators occur in various branches of analysis. For example, it is shown in [6] that the existence of certain types of liftings is closely related to the solvability of systems of difference equations. Among others, it is obtained from results on the solvability of infinite systems of difference equations that there exists a linear operator from the bounded real functions into the set of measurable real functions that fixes the bounded measurable functions and commutes with any prescribed countable set of translations [6, Theorem 3.3]. On the other hand, there is no such linear operator from the space of all complex valued functions defined on $\mathbb{R}$ into the space $L^0$ of measurable functions; see [6, Theorem 5.1 and 5.2].

The goal of this paper is to give necessary conditions under which systems of difference equations have solutions belonging to a given function class.

Notation 1.1 Let $\mathbb{R}^R$ denote the set of real valued functions defined on the real line. The classes of polynomials and trigonometric polynomials are denoted by $P$ and $TP$. For every set $H$ we shall denote by $\chi_H$ and $|H|$ the characteristic function and the cardinality of $H$. We denote the symmetric difference of the sets $A$ and $B$ by $A\Delta B$. If $A, B \subseteq \mathbb{R}$ and $x \in \mathbb{R}$ then we shall write $A + B = \{a + b : a \in A, b \in B\}$ and $A + x = \{a + x : a \in A\}$. If $A \subseteq \mathbb{R}$ then $\langle A \rangle$ denotes the additive group generated by $A$. The symbols $\kappa^+$ and $\text{cf}(\kappa)$ denote the successor cardinal and the cofinality of the cardinal $\kappa$.

Definition 1.2 A difference operator is a mapping $D : \mathbb{R}^R \to \mathbb{R}^R$ of the form

$$(Df)(x) = \sum_{i=1}^{n} a_i f(x + b_i),$$

where $a_i$ and $b_i$ are real numbers. The set of difference operators is denoted by $D$.

Definition 1.3 For $b \in \mathbb{R}$ the difference operators $T_b$ and $\Delta_b$ are defined by

$$(T_b f)(x) = f(x + b) \quad (x \in \mathbb{R}), \quad \text{and}$$
$$(\Delta_b f)(x) = f(x + b) - f(x) \quad (x \in \mathbb{R}).$$

Definition 1.4 A difference equation is a functional equation

$$Df = g,$$

where $D$ is a difference operator, $g$ is a given function and $f$ is the unknown. A system of difference equations is

$$D_i f = g_i \quad (i \in I),$$

where $I$ is an arbitrary set of indices. More formally, by a system of difference equations we mean a set $S \subseteq D \times \mathbb{R}^R$. A function $f : \mathbb{R} \to \mathbb{R}$ is a solution to $S$ if $Df = g$ for every $(D, g) \in S$. 
It was proved in [6, Thm. 2.2] that a system of difference equations is solvable iff each of its finite subsystems is solvable. However, if we are interested in solutions belonging to a given subclass of $\mathbb{R}^R$ then this result is no longer true. This motivates the following.

**Definition 1.5** Let $\mathcal{F} \subset \mathbb{R}^R$ be a class of real functions. The **solvability cardinal** of $\mathcal{F}$ is the minimal cardinal $\text{sc}(\mathcal{F})$ with the property that if every subsystem of size less than $\text{sc}(\mathcal{F})$ of a system of difference equations has a solution in $\mathcal{F}$, then the whole system has a solution in $\mathcal{F}$.

For example, $\text{sc}(\mathbb{R}^R) \leq \omega$ is a reformulation of the above cited result. The next statement shows that the cardinal $\text{sc}(\mathcal{F})$ actually exists, and also provides an upper bound.

**Fact 1.6** For every $\mathcal{F} \subset \mathbb{R}^R$ we have $\text{sc}(\mathcal{F}) \leq (2^\omega)^+$.

**Proof.** Note that the cardinality of $D$ is $2^\omega$. Suppose $\mathcal{F} \subset \mathbb{R}^R$, $S$ is system of difference equations, and every subsystem of $S$ of cardinality at most $2^\omega$ is solvable in $\mathcal{F}$. In particular, every pair of equations of $S$ is solvable, hence for every $D \in D$ there is at most one $g \in \mathbb{R}^R$ such that $(D, g) \in S$. Therefore the cardinality of $S$ is at most $2^\omega$, and we are done. □

We may add the following trivial estimate.

**Fact 1.7** For every $\mathcal{F} \subset \mathbb{R}^R$ we have $\text{sc}(\mathcal{F}) \leq |\mathcal{F}|^+$.

**Proof.** Let $S$ be a system of difference equations such that every subsystem of $S$ of cardinality at most $|\mathcal{F}|$ is solvable in $\mathcal{F}$. Suppose $S$ is not solvable in $\mathcal{F}$. Then for every $f \in \mathcal{F}$ there is a $(D_f, g_f) \in S$ such that $D_f f \neq g_f$. Then $S' = \{(D_f, g_f) : f \in \mathcal{F}\}$ has no solution in $\mathcal{F}$ and $|S'| \leq |\mathcal{F}|$, a contradiction. □

**Remark 1.8** Fact 1.7 can be improved if we take into consideration the product topology on $\mathbb{R}^R$. Namely, if $D f \neq g$ for some $f \in \mathbb{R}^R$ then $f$ has a neighbourhood $U$ in the product topology such that $D f' \neq g$ for every $f' \in U$. Combining this observation with the proof of Fact 1.6 we obtain the estimate $\text{sc}(\mathcal{F}) \leq L(\mathcal{F})^+$, where $L(X)$ is the Lindelöf number of the topological space $X$; that is, the smallest cardinal $\kappa$ such that each open cover of $X$ contains a subcover of cardinality at most $\kappa$. This sharper inequality implies Fact 1.6 since the space $\mathbb{R}^R$ has a base of cardinality $2^\omega$ and thus $L(X) \leq 2^\omega$ for every subspace $X \subset \mathbb{R}^R$.

It is natural to ask whether or not every cardinal $2 \leq \kappa \leq (2^\omega)^+$ equals $\text{sc}(\mathcal{F})$ for some $\mathcal{F} \subset \mathbb{R}^R$. As we shall see in Theorem 2.1, $\omega$ is such a cardinal. The following result gives a positive answer for successor cardinals.

**Theorem 1.9** For every cardinal $1 \leq \kappa \leq 2^\omega$ there exists an $\mathcal{F} \subset \mathbb{R}^R$ such that $\text{sc}(\mathcal{F}) = \kappa^+$.  

3
Proof. Let $B \subset \mathbb{R}$ be linearly independent over the rationals with $|B| = \kappa$. For every $b \in B$ we denote by $f_b$ the characteristic function of the group $(B \setminus \{b\})$. Then $f_b$ is periodic mod each element of $B \setminus \{b\}$, but $f_b$ is not periodic mod $b$.

We claim that the solvability cardinal of the class $\mathcal{F} = \{f_b : b \in B\}$ equals $\kappa^+$. The inequality $sc(\mathcal{F}) \leq \kappa^+$ is clear from Fact 1.7. In order to prove $sc(\mathcal{F}) \geq \kappa^+$ we have to construct a system $S$ such that every subsystem $S' \subset S$ of size less than $\kappa$ is solvable in $\mathcal{F}$, while $S$ is not. We show that $S = \{(\Delta_b, 0) : b \in B\}$ is such a system. If $b \in B$ then, as $f_b$ is not periodic mod $b$, we have $\Delta_b f_b \neq 0$ showing that $S$ is not solvable in $\mathcal{F}$. On the other hand, if $S'$ is a proper subsystem of $S$ and $(\Delta_b, 0) \notin S'$ then $f_b$ solves $S'$ completing the proof. □

Question 1.10 Is it true (in ZFC) that for every $2 \leq \kappa \leq (2^\omega)^+$ there exists an $F \subset \mathbb{R}$ such that $sc(F) = \kappa$? Is there (in ZFC) an $F$ with $sc(F) = 2^\omega$? Is it consistent with ZFC that $sc(F)$ can be an uncountable limit cardinal?

In the first part of the paper (Sections 2, 3, 4, and 5) we determine the exact value of $sc(F)$ for several classes $F$; see Theorems 2.1, 3.2, 3.3, 4.1, Corollaries 5.4, 5.5 and Theorem 5.6. As it turns out, the behaviour of $sc(F)$ is rather erratic. For example, $sc(P) = 3$, but $sc(TP) = \omega_1$; $sc(\mathbb{R}) = \omega$, but $sc(\{f : f$ is Darboux\}) $\geq \omega_1$ answers Problem 3 of [6].

2 Arbitrary functions

The nontrivial direction of the next theorem was proved in [6, Thm. 2.2], but we reformulate this result using the notation introduced in the present paper.

Theorem 2.1 $sc(\mathbb{R}) = \omega$.

Proof. $sc(\mathbb{R}) \leq \omega$ is [6, Thm. 2.2], so we only need to show that $sc(\mathbb{R}) \neq n$ for every $n \in \mathbb{N}$. Let $n \geq 2$, let $a_1, \ldots, a_{n-1} \in \mathbb{R}$ be linearly independent over the rationals, and put $a_n = -\sum_{i=1}^{n-1} a_i$. Then any $n - 1$ of the numbers $a_1, \ldots, a_n$ are linearly independent over the rationals. Define the following system of $n$ equations:

$$\Delta_{a_i}f = 1, \quad i = 1, \ldots, n.$$ 

It is easy to see that each subsystem of cardinality at most $n - 1$ is solvable (consider the factor group of $\mathbb{R}$ modulo the additive group generated by the corresponding linearly independent $a_i$’s). On the other hand, if $f$ were a solution to the whole system, then $f(0) + n = f(a_1 + \ldots + a_n) = f(0)$ would hold, which is impossible. This shows $sc(\mathbb{R}) > n$ and, as $n$ was arbitrary, the proof is complete. □
3 Bounded functions

It is well known that the difference operators form an algebra under the operations \((A + B)f = Af + Bf, \ (c \cdot A)f = c \cdot Af\) and \((AB)f = A(Bf)\).

**Definition 3.1** We say that the difference equation \((D, g)\) is deducible from the system \(S\) if there are \(A_1, \ldots, A_n \in D\) and \((D_1, g_1), \ldots, (D_n, g_n) \in S\) such that \((D, g) = (\sum_{i=1}^n A_i D_i, \sum_{i=1}^n A_i g_i)\).

**Theorem 3.2** Let \(K > 0\) be a real number. Then \(\text{sc}(\{f \in \mathbb{R} : |f| \leq K\}) = \omega\).

**Proof.** We may assume \(K = 1\). First we show \(\text{sc}(\{f \in \mathbb{R} : |f| \leq 1\}) \leq \omega.\)

The proof is a modification of the proof of [6, Thm. 2.1], the new ingredient is the Hahn-Banach Theorem. Let \(S\) be a system such that all finite subsystems are solvable by functions of absolute value at most 1. Define

\[ A = \{D \in D : \exists g \ (D, g) \text{ is deducible from } S\}. \]

Then \(A\) is a linear subspace of \(D\). Put

\[ L(D) = g(0) \quad (D \in A), \]

where \((D, g)\) is deducible from \(S\). Clearly, if \((D, g)\) is deducible from \(S\) then it is also deducible from a finite subsystem of \(S\), hence it is solvable. Moreover, any pair of equations deducible from \(S\) has a common solution. Therefore the map \(L : A \rightarrow \mathbb{R}\) is well defined. Note that \(L\) is clearly linear.

Now we define a norm on \(D\). It is easy to see that every \(D \in D\) has a unique representation of the form \(D = \sum_{i=1}^n a_i T_{b_i}\), where the \(a_i\)'s are nonzero and the \(b_i\)'s are different. Using this representation set

\[ ||D|| = \sum_{i=1}^n |a_i|. \]

The function \(|| \cdot || : D \rightarrow \mathbb{R}\) is easily seen to be a norm.

We claim that for every \(D \in A\) we have \(|L(D)| \leq ||D||\). Let \((D, g)\) be deducible from \(S\). Then there is a function \(f\) such that \(|f| \leq 1\) and \(Df = g\). If \(D = \sum_{i=1}^n a_i T_{b_i}\) then

\[ |L(D)| = |g(0)| = \left| \sum_{i=1}^n a_i f(b_i) \right| \leq \sum_{i=1}^n |a_i| \cdot 1 = ||D||. \]

Hence by the Hahn-Banach Theorem (see e.g. [10, Thm. 3.3]) there exists a linear map \(L^* : D \rightarrow \mathbb{R}\) extending \(L\) such that

\[ |L^*(D)| \leq ||D|| \] for every \(D \in D\).

We claim that the function defined by

\[ f(x) = L^*(T_x) \quad (x \in \mathbb{R}) \]
is a solution to $S$ such that $|f| \leq 1$. This last inequality is obvious, as $|f(x)| = |L^*(T_x)| \leq ||T_x|| = 1$. So we need to prove that $f$ solves $S$. First we show that

$$(Df)(0) = L^*(D) \text{ holds for every } D \in \mathcal{D}. \quad (1)$$

Since $L^*$ is linear, it is enough to check this for $D = T_x$ ($x \in \mathbb{R}$). Now $(T_x f)(0) = f(x) = L^*(T_x)$ by the definition of $f$, which proves $(1)$. Let $(D, g) \in S$ and $x \in \mathbb{R}$ be given. Then $T_x D \in A$, and thus $(1)$ and the definition of $L$ imply

$$(Df)(x) = (T_x D f)(0) = L^*(T_x D) = L(T_x D) = (T_x g)(0) = g(x).$$

Now we prove $\operatorname{sc}(|f| \leq 1) \geq \omega$. Let $n \geq 2$ be an integer and let $a_1, \ldots, a_n$ be linearly independent reals. Define a system as follows.

$$\Delta a_i f = \frac{2}{n-1} \chi_{\{a_1, \ldots, a_{i-1}, a_{i+1}, \ldots, a_n\}}, \quad (i = 1, \ldots, n).$$

A simple induction shows that if $f$ solves the whole system, then $f(a_1 + \ldots + a_n) - f(0) = \frac{2n}{n-1} > 2$, hence $|f| \leq 1$ cannot hold.

On the other hand, let $J \subset \{1, \ldots, n\}$ be a set of at most $n-1$ elements. Every $x \in \{a_1, \ldots, a_n\}$ can be uniquely written in the form $x = k_1(x) a_1 + \ldots + k_n(x) a_n$, where the $k_i(x)$’s are integers. Define

$$f(x) = \begin{cases} 0 & \text{if } x \notin \{a_1, \ldots, a_n\} \\ -1 + \frac{2}{n-1} |\{i \in J : k_i(x) > 0\}| & \text{if } x \in \{a_1, \ldots, a_n\}. \end{cases}$$

Clearly, $|f| \leq 1$. It is easy to see that $f$ solves the $i^{th}$ equation for every $i \in J$, which yields $\operatorname{sc}(|f| \leq 1) > n$. As $n$ was arbitrary, the proof is complete. \hfill \Box

In contrast to Theorem 3.2, we have the following.

**Theorem 3.3** $\operatorname{sc}(|f| \leq 1) = \omega_1$.

**Proof.** First we prove $\operatorname{sc}(|f| \leq 1) \leq \omega_1$. Let $S$ be a system such that every countable subsystem of $S$ is solvable by a bounded function. For a countable $S' \subset S$ let $K_{S'}$ be the minimal integer for which $S'$ has a solution in $\{f \in \mathbb{R}^n : |f| \leq K_{S'}\}$. The set $\{K_{S'} : S' \subset S, |S'| \leq \omega\}$ is bounded in $\mathbb{N}$, otherwise we could easily find a countable subsystem of $S$ with no bounded solutions. Fix an upper bound $K$ of the above set. Then every countable, in particular, every finite subsystem of $S$ is solvable in $\{f \in \mathbb{R}^n : |f| \leq K\}$, hence by the previous theorem $S$ is solvable in $\{f \in \mathbb{R}^n : |f| \leq K\}$, hence $S$ has a bounded solution.

Now we prove $\operatorname{sc}(|f| \leq 1) > \omega$. Similarly to the previous theorem, let $a_1, a_2, \ldots$ be a linearly independent sequence of reals. Define a system by

$$\Delta a_i f = \chi_{\{a_1, \ldots, a_{i-1}, a_{i+1}, \ldots\}}, \quad (i \in \mathbb{N}^+).$$
A simple induction shows that if \( f \) solves the whole system, then \( f(a_1 + \ldots + a_n) - f(0) = n \) for every \( n \), hence \( f \) cannot be bounded.

On the other hand, let \( J \subset \mathbb{N}^+ \) be a finite set. Every \( x \in \langle \{a_1, a_2, \ldots \} \rangle \) can be uniquely written in the form \( x = k_1(x)a_1 + k_2(x)a_2 + \ldots \), where the \( k_i(x) \)'s are integers, and only finitely many of them are nonzero. Similarly to the proof of the previous theorem one can check that

\[
f(x) = \begin{cases} 0 & \text{if } x \notin \langle \{a_1, a_2, \ldots \} \rangle \\ |\{i \in J : k_i(x) > 0\}| & \text{if } x \in \langle \{a_1, a_2, \ldots \} \rangle \end{cases}
\]

is a bounded solution to the finite subset of \( S \) corresponding to \( J \). \( \square \)

4 Darboux functions

**Theorem 4.1** \( \text{sc(\{f : f \text{ is Darboux}\})} = (2^{\omega})^+ \).

**Proof.** \( \text{sc(\{f : f \text{ is Darboux}\})} \leq (2^{\omega})^+ \) follows from Fact 1.6. In order to prove the other inequality we have to construct a system \( S \) such that every subsystem of cardinality less than continuum is solvable by a Darboux function but \( S \) has no Darboux solution. We define \( S \) as

\[
\Delta_b f = \Delta_b 1_{\{0\}} \quad (b \in \mathbb{R}).
\]

The whole system clearly has no Darboux solution, for if \( f \) is a solution to \( S \) then there exists a \( c \in \mathbb{R} \) such that \( f = 1_{\{0\}} + c \), which is not Darboux. On the other hand, let \( S' \) be a subset of \( S \) such that \( |S'| < 2^\omega \), and let \( B \subset \mathbb{R} \) be the corresponding set of indices with \( |B| < 2^\omega \). By enlarging \( B \) if necessary, we may assume that \( B \) is an additive subgroup of \( \mathbb{R} \), and also that \( B \) is dense.

As \( |B| < 2^\omega \), the factor group \( \mathbb{R}/B \) consists of \( 2^\omega \) cosets. Fix a bijection \( \varphi : \mathbb{R}/B \to \mathbb{R} \) and define

\[
f(x) = \varphi(B + x) + 1_{\{0\}}(x) \quad (x \in \mathbb{R}).
\]

As \( B \) is dense, \( f \) attains every value on every interval, hence it is Darboux. In addition, it is easy to see that \( f \) solves \( S' \). \( \square \)

**Remark 4.2** The same system can be used to demonstrate that for the class \( \mathcal{F} \) of functions with connected graphs we also have \( \text{sc(\mathcal{F})} = (2^{\omega})^+ \). With a more elaborate version of the argument above it can be shown that if \( |B| < 2^\omega \) then the system \( \{(\Delta_b, \Delta_b 1_{\{0\}}) : b \in B\} \) has a solution with a connected graph.

5 Subclasses of Lebesgue measurable and Baire measurable functions

In this section our aim is to prove that \( \text{sc(\mathcal{F})} = \omega_1 \) for many classes including the classes of trigonometric polynomials, continuous functions, Lipschitz functions,
$C^n$, $C^\infty$, analytic functions, derivatives, approximately continuous functions etc.

Let $\mathcal{N}$ denote the $\sigma$-ideal of Lebesgue nullsets of $\mathbb{R}$ and $\mathcal{M}$ denote the $\sigma$-ideal of first category (= meager) subsets of $\mathbb{R}$. In the rest of the section let $\mathcal{I}$ stand for either $\mathcal{N}$ or $\mathcal{M}$. The term $\mathcal{I}$-almost everywhere will be abbreviated by $\mathcal{I}$-a.e.

Instead of 'Lebesgue measurable' and 'with the Baire property' we will use the term $\mathcal{B}_\sigma$-measurable, where $\mathcal{B}_\sigma$ is the $\sigma$-algebra generated by the Borel sets and $\mathcal{I}$.

First we show that if we do not distinguish between $\mathcal{I}$-almost everywhere equal functions, then the value of this modified solvability cardinal is at most $\omega_1$ for all subclasses of both Lebesgue measurable functions and functions with the property of Baire.

**Theorem 5.1** Let $\mathcal{F} \subset \mathcal{B}_\sigma$, and suppose that for every countable subsystem $S'$ of a system of difference equations $S$ there exists an $f' \in \mathcal{F}$ such that $Df' = g$ $\mathcal{I}$-a.e. for every $(D, g) \in S'$. Then there is an $f \in \mathcal{F}$ such that $Df = g$ $\mathcal{I}$-a.e. for every $(D, g) \in S$.

**Proof.** Let $S$ be a system satisfying the assumptions. Every $D \in \mathcal{D}$ can be written in a unique way as $D = \sum_{i=1}^{n} a_i T_{b_i}$. Define $\varphi : \mathcal{D} \to \bigcup_{n \in \mathbb{N}} \mathbb{R}^{2n}$ by

$$\varphi(D) = (a_1, \ldots, a_n, b_1, \ldots, b_n) \quad (D \in \mathcal{D}).$$

Set $S_n = \{(D, g) \in S : D \text{ has } n \text{ terms}\}$. For every $n \in \mathbb{N}$ choose a countable $S'_n \subset S_n$ such that $\{\varphi(D) : (D, g) \in S'_n \} \subset \mathbb{R}^{2n}$ is dense in $\{\varphi(D) : (D, g) \in S_n \} \subset \mathbb{R}^{2n}$.

Let $f \in \mathcal{F}$ be a function 'I-a.e.' solving $\bigcup_{n \in \mathbb{N}} S'_n$. We claim that it 'I-a.e.' solves the whole $S$. Let $(D, g) \in S_n$, and choose $(D_i, g_i) \in S'_n$ such that $\varphi(D_i) \to \varphi(D)$ in $\mathbb{R}^{2n}$.

Suppose first $\mathcal{I} = \mathcal{N}$. It is well known that for every measurable $h$ if $t_n \to 0$ $(n \to \infty)$ then $T_{t_n} h \to h$ in measure (which means that it converges in measure on every bounded interval; see e.g. [11] or [2] for the definitions and basic facts). Hence $D_i h \to D h$ in measure. Let $f'$ be an a.e. solution to $\bigcup_{n \in \mathbb{N}} S'_n \cup \{(D, g)\}$. Then

$$Df = \lim_{t \to \infty} D_i f = \lim_{t \to \infty} g_i = \lim_{t \to \infty} D_i f' = D f' = g$$

a.e., where lim stands for limit in measure.

Suppose now $\mathcal{I} = \mathcal{M}$. We claim that for every $h$ with the Baire property if $t_n \to 0$ $(n \to \infty)$ then $T_{t_n} h \to h$ pointwise on a residual set. Indeed, if $H$ is a residual set on which $h$ is continuous then $H \cap \bigcap_{n \in \mathbb{N}} (H - t_n)$ is such a set. Therefore $D_i h \to D h$ pointwise on a residual set. Let $f'$ be an $\mathcal{M}$-a.e. solution to $\bigcup_{n \in \mathbb{N}} S'_n \cup \{(D, g)\}$. Then

$$Df = \lim_{t \to \infty} D_i f = \lim_{t \to \infty} g_i = \lim_{t \to \infty} D_i f' = D f' = g$$

on a residual set. \qed
Theorem 5.2 Let $\mathcal{F} \subset \tilde{\mathcal{F}} \subset \mathcal{B}_\mathbb{R}$, where $\tilde{\mathcal{F}}$ is a translation invariant linear subspace of $\mathcal{B}_\mathbb{R}$ such that whenever $f \in \mathcal{F}$ and $f = 0$ $\mathcal{I}$-a.e. then $f = 0$ everywhere. Then $\text{sc}(\mathcal{F}) \leq \omega_1$.

Proof. Suppose that every countable subsystem of $S$ has a solution in $\mathcal{F}$. Then obviously $g \in \tilde{\mathcal{F}}$ whenever $(D, g) \in S$.

By Theorem 5.1 there is an $f \in \mathcal{F}$ such that $Df = g$ $\mathcal{I}$-a.e. for every $(D, g) \in S$. Since $Df - g \in \tilde{\mathcal{F}}$ and $Df - g = 0$ $\mathcal{I}$-a.e., we have $Df = g$, which proves $\text{sc}(\mathcal{F}) \leq \omega_1$. \hfill \Box

It is clear that the class $C(\mathbb{R})$ of continuous functions satisfies the conditions imposed on $\tilde{\mathcal{F}}$. The same is true for the classes of derivatives and approximately continuous functions (see [1]).

We shall denote by $\mathcal{T}\mathcal{P}$ the set of trigonometric polynomials.

Theorem 5.3 If $\mathcal{T}\mathcal{P} \subset \mathcal{F} \subset \mathcal{B}_\mathbb{R}$ then $\text{sc}(\mathcal{F}) \geq \omega_1$.

Proof. We shall construct a system $S$ such that every finite subsystem of $S$ has a solution which is a trigonometric polynomial, but $S$ itself does not have a $\mathcal{B}_\mathbb{R}$-measurable solution. We shall repeat the construction of [6, Thm. 4.4] with a small modification.

Let $C(x) = \cos 2\pi x$ and $E_{j,n}(x) = \Delta_{2^{-n}}C(2^j x)$, then $E_{j,n} \in \mathcal{T}\mathcal{P}$ for every $j, n \in \mathbb{N}$. Also, $E_{j,n} = 0$ if $j \geq n$ and, if $j < n$ then $E_{j,n}$ is a continuous function periodic mod 1 with finitely many roots in $[0, 1]$.

Let $c_j (j = 0, 1, \ldots)$ be a sequence of real numbers, and consider the system $S$ of the equations

$$\Delta_{2^{-n}} f = h_n, \quad \text{where} \quad h_n = \sum_{j=0}^{n-1} c_j E_{j,n} \quad (n = 1, 2, \ldots).$$

Then the trigonometric polynomial $\sum_{j=0}^{n-1} c_j C(2^j x)$ is a solution to the first $n$ equations of $S$. On the other hand, we shall choose the numbers $c_j$ in such a way that $S$ does not have $\mathcal{B}_\mathbb{R}$-measurable solutions.

First suppose $\mathcal{I} = \mathcal{N}$. If $f : \mathbb{R} \to \mathbb{R}$ is measurable then the sequence of functions $\Delta_{2^{-n}} f$ converges to zero in measure on $[0, 1]$. Therefore, if $S$ has a measurable solution, then $h_n$ should converge to zero in measure on $[0, 1]$. But we can prevent this by a suitable choice of the sequence $c_j$. We shall define $c_j$ inductively. If $c_j$ has been defined for every $j < n - 1$, then we choose $c_{n-1}$ so large that $\lambda(\{x \in [0, 1] : |h_n(x)| > 1\}) > 1/2$ holds. This is possible, since $E_{n-1,n} \neq 0$ a.e. in $[0, 1]$. Therefore, with this choice, $h_n$ does not converge (in measure) to zero on $[0, 1]$, and thus $S$ cannot have measurable solutions.

Next suppose $\mathcal{I} = \mathcal{M}$. If $f : \mathbb{R} \to \mathbb{R}$ is Baire measurable then the sequence of functions $\Delta_{2^{-n}} f$ converges to zero pointwise on a residual subset of $[0, 1]$. Again, we shall choose the constants $c_j$ such that $h_n \not\to 0$ on a second category set. Namely, we shall define $c_j$ in such a way that each function $h_n$ satisfies the following condition: for every interval $I \subset [0, 1]$ of length $1/n$ the inequality $|h_n| > 1$ holds on a subinterval of $I$. (In the course of the proof by an interval
we shall mean a closed nondegenerate interval, and by $|I|$ we shall mean the length of the interval $I$.

We put $c_0 = 1$. Then $h_1(x) = C(x + \frac{1}{n}) - C(x) = -2 \cos 2\pi x$ has the required property with $n = 1$, since there is a subinterval of $[0, 1]$ on which $|h_1| > 1$. Let $n > 1$ and suppose that $c_0, \ldots, c_{n-2}$ have been chosen. Since $E_{n-1,n}$ only has a finite number of roots in $[0, 1]$, the function

$$h_n = \left(\sum_{j=0}^{n-2} c_j E_{j,n}\right) + c_{n-1} E_{n-1,n}$$

clearly has the required property if $c_{n-1}$ is large enough.

We show that the set $A = \{ x \in [0, 1] : h_n(x) \to 0 \}$ is not residual. Suppose the contrary, and let $\bigcap_{k=1}^{\infty} U_k \subset A$, where each $U_k$ is dense open. Let $I_1 \subset U_1$ be an interval. If $1/n_1 < |I_1|$ then there is a subinterval $J_1 \subset I_1$ such that $|h_{n_1}| > 1$ on $J_1$. Since $U_2$ is dense open, there is an interval $I_2 \subset U_2 \cap J_1$. If $1/n_2 < |I_2|$ then there is a subinterval $J_2 \subset I_2$ such that $|h_{n_2}| > 1$ on $J_2$. Continuing this process we find the nested sequence of intervals $J_k$ such that $\bigcap_{k=1}^{\infty} J_k \subset \bigcap_{k=1}^{\infty} U_k \subset A$ and $|h_{n_k}| > 1$ on $J_k$ for every $k$. This implies $h_n(x) \not\to 0$ for every $x \in \bigcap_{k=1}^{\infty} J_k$, which contradicts $x \in A$. \hfill \Box

**Corollary 5.4** Suppose $\mathcal{T} \mathcal{P} \subset \mathcal{F} \subset \mathcal{F} \subset B_T$, where $\mathcal{F}$ is a translation invariant linear subspace of $B_T$ such that whenever $f \in \mathcal{F}$ and $f = 0$ $I$-a.e. then $f = 0$ everywhere. Then $sc(\mathcal{F}) = \omega_1$.

It is clear that the class $C(\mathbb{R})$ of continuous functions satisfies the conditions imposed on $\mathcal{F}$. The same is true for the classes of derivatives and approximately continuous functions (see [II]). Thus we have the following.

**Corollary 5.5** If $\mathcal{F}$ equals any of the classes $\mathcal{T} \mathcal{P}$, $C(\mathbb{R})$, the class of Lipschitz functions, $C^n(\mathbb{R})$, $C^\infty(\mathbb{R})$, the class of real analytic functions, derivatives, approximately continuous functions, then $sc(\mathcal{F}) = \omega_1$. The same is true for the subclasses $\{ f \in \mathcal{F} : f$ is bounded $\}$ where $\mathcal{F}$ is any of the classes listed above.

We remark that the class $\mathcal{P}$ of polynomials behaves quite differently from $\mathcal{T} \mathcal{P}$. Indeed, [II Thm. 4.5] states that $sc(\mathcal{P}) \leq 3$. Since $sc(\mathcal{P}) \geq 3$ is obvious, we have the following.

**Theorem 5.6** $sc(\mathcal{P}) = 3$.

### 6 Borel functions

First we prove an auxiliary lemma.

**Lemma 6.1** There exist non-empty perfect subsets $\{ P_\alpha : \alpha < 2^\omega \}$ of $\mathbb{R}$ and distinct real numbers $\{ p_\alpha : \alpha < 2^\omega \}$ such that

$$(P_\alpha + G_{\alpha+1}) \cap (P_\beta + G_{\beta+1}) = \emptyset \quad (\alpha \neq \beta),$$

10
and for every $\alpha < 2^\omega$

$$(P_\alpha + g_1) \cap (P_\alpha + g_2) = \emptyset \quad (g_1, g_2 \in G_{\alpha+1}, \ g_1 \neq g_2),$$

where $G_\alpha = \langle \{p_\beta : \beta < \alpha\} \rangle$.

**Proof.** Let $P \subset \mathbb{R}$ be a non-empty perfect set that is linearly independent over the rationals (see e.g. [9] or [8]). We can choose nonempty perfect sets $P_\alpha \subset P$ and $p_\alpha \in P$ ($\alpha < 2^\omega$) such that $P_\alpha \cap P_\beta = \emptyset$ for every $\alpha \neq \beta$ and such that $p_\alpha \notin P_\beta$ for every $\alpha, \beta < 2^\omega$. It is a straightforward calculation to check that all the requirements are fulfilled. \hfill \Box

**Theorem 6.2** $\text{sc}(\{f : f \text{ is Borel}\}) \geq \omega_2$.

**Proof.** Let $P_\alpha$ and $p_\alpha$ be as in the previous lemma. For every $\alpha < \omega_1$ let $B_\alpha \subset P_\alpha$ be a Borel set of class $\alpha$ (that is, not of any smaller class). Define $A_\alpha = B_\alpha + G_\alpha$, and consider the system of difference equations:

$$\Delta p_\alpha f = \Delta p_\alpha \left( \sum_{\beta < \omega_1} \chi_{A_\beta} \right) \quad (\alpha < \omega_1).$$

Note that the $A_\beta$’s are disjoint. We claim that every countable subsystem of this system has Borel solution, but the whole system does not.

To prove the first statement we have to check that for every $\alpha < \omega_1$ the first $\alpha$ equations have a common Borel solution. We show that the Borel function

$$\sum_{\beta \leq \alpha} \chi_{A_\beta}$$

will do. If $\gamma < \beta$ then $A_\beta$ is periodic mod $p_\gamma$, so $\Delta p_\gamma \chi_{A_\beta} = 0$. Therefore, in view of the properties required in Lemma 6.1 we obtain that for $\gamma < \alpha$

$$\Delta p_\gamma \left( \sum_{\beta < \omega_1} \chi_{A_\beta} \right) = \Delta p_\gamma \left( \sum_{\beta \leq \alpha} \chi_{A_\beta} \right),$$

which proves this part of the claim.

In order to show that the whole system has no Borel solution it is sufficient to check that the functions on the right hand side of the equations are of unbounded Baire class. But this is not hard to see, as $\Delta p_\alpha (\sum_{\beta < \omega_1} \chi_{A_\beta})$ restricted to $P_\alpha$ equals $-\chi_{B_\alpha}$. \hfill \Box

Using Fact 1.6 we obtain the following.

**Corollary 6.3** The Continuum Hypothesis implies that $\text{sc}(\{f : f \text{ is Borel}\}) = \omega_2 = (2^\omega)^+.$

**Question 6.4** Can we omit the use of the Continuum Hypothesis? Is it true that $\text{sc}(\{f : f \text{ is Borel}\}) = \omega_2$? Is it true that $\text{sc}(\{f : f \text{ is Borel}\}) = (2^\omega)^+?$
Remark 6.5 In order to prove $\text{sc}\{f : f \text{ is Borel}\} = \omega_2$ it would be sufficient to prove $\text{sc}\{f : f \text{ is Baire class } \alpha\} \leq \omega_2$ for every $\alpha < \omega_1$. Indeed, assume that every subsystem of cardinality at most $\omega_1$ of a system has a Borel solution. Let us assign to every such subsystem the minimal $\alpha < \omega_1$ for which it has a Baire class $\alpha$ solution. We claim that the set of these $\alpha$’s is bounded in $\omega_1$. Otherwise, the union of $\omega_1$-many appropriate subsystems would itself be a subsystem of cardinality $\omega_1$ without a Borel solution, which proves our statement.

So if every subsystem of cardinality at most $\omega_1$ of a system has a Borel solution, then there exists an $\alpha < \omega_1$ such that every such subsystem has a Baire class $\alpha$ solution.

Remark 6.6 For $2 \leq \alpha < \omega_1$ the idea of the proof of Theorem 6.2 probably gives $\text{sc}\{f : f \text{ is Baire class } \alpha\} \geq \omega_2$. If we had an appropriate notion of rank for Baire class $\alpha$ functions, sharing the properties of the well known ranks on Baire class 1, it would yield $\text{sc}\{f : f \text{ is Baire class } \alpha\} \geq \omega_2$. Unfortunately, according to [4] no such rank is known.

For Baire class 1 these ranks exist, but do not give $\text{sc}\{f : f \text{ is Baire class } 1\} \geq \omega_2$. The proof breaks down, as $\sum_{\beta \leq \alpha} \chi_{A_\beta}$ is not Baire class 1.

Question 6.7 Is there a rank on Baire class $\alpha$ with the usual properties?

Remark 6.5 shows why we are particularly interested in the solvability cardinals of the individual Baire $\alpha$ classes. The simplest case, namely $C(\mathbb{R})$ is solved already. So we take one step further.

7 Baire class 1 functions

It is clear from Theorem 6.3 that $\text{sc}\{f : f \text{ is Baire class } 1\} \geq \omega_1$. As opposed to the case $2 \leq \alpha < \omega_1$ we conjecture that, in fact, $\text{sc}\{f : f \text{ is Baire class } 1\} = \omega_1$. Unfortunately, we only can prove this in a special case. What makes this case interesting is that it covers the usual situation in which every difference operator $D$ is of the form $D = \Delta_b$.

First we need two lemmas.

Lemma 7.1 Let $a, b \in \mathbb{R} \setminus \{0\}$. The solutions to the equation

$$f(x + b) - af(x) = 0$$

are the functions of the form

$$f(x) = \varphi(x)(|a|^{1/b})^x,$$

where $\varphi$ is an arbitrary function periodic mod $b$ if $a > 0$, and an arbitrary function anti-periodic mod $b$ (that is, $\varphi(x + b) = -\varphi(x)$ for every $x \in \mathbb{R}$) if $a < 0$.

In addition, $f$ is Baire class 1 iff $\varphi$ is Baire class 1.
Proof. Straightforward calculations. \(\square\)

**Lemma 7.2** Let \(a_1, a_2, b_1, b_2 \in \mathbb{R} \setminus \{0\}\). Suppose that the equations \(f(x + b_1) - a_1 f(x) = 0\) and \(f(x + b_2) - a_2 f(x) = 0\) have a common Baire class 1 solution which is not identically zero. Then \(|a_1|^{1/b_1} = |a_2|^{1/b_2}\).

**Proof.** Suppose this is not true. Then by the previous lemma there exist two Baire class 1 functions \(\varphi_1\) and \(\varphi_2\) such that

\[
\varphi_1(x)(|a_1|^{1/b_1})^x = \varphi_2(x)(|a_2|^{1/b_2})^x,
\]

where \(\varphi_1\) and \(\varphi_2\) are periodic (or anti-periodic) mod \(b_1\) and \(b_2\), respectively. We may assume that both functions are periodic, otherwise we could consider \(\psi_i(x) = \varphi_i(2x)\) for \(i = 1, 2\). We can also assume that \(|a_1|^{1/b_1} < |a_2|^{1/b_2}\), and therefore

\[
\varphi_1(x) = \varphi_2(x)c^x, \quad \text{where } c > 1. \tag{2}
\]

Finally, as \(\varphi_2\) is not identically zero, we can also suppose (by applying an appropriate translation if needed) that \(\varphi_2(0) \neq 0\).

Suppose that \(b_1/b_2 \in \mathbb{Q}\). Then \(\varphi_1\) and \(\varphi_2\) are periodic mod a common value \(p\). But this is impossible, since \(c^x \neq 1\) when \(x \neq 0\).

Therefore \(b_1/b_2 \notin \mathbb{Q}\). Then for every (nondegenerate) interval \(I \subset \mathbb{R}\) there exist integers \(n, k \in \mathbb{Z}\) with \(k\) arbitrarily large such that \(nb_1 + kb_2 \in I\). By substituting \(kb_2\) into (2) we get \(\varphi_1(kb_2) = \varphi_2(kb_2)c^{kb_2}\) for every \(k \in \mathbb{Z}\), thus \(\varphi_1(kb_2) = \varphi_2(0)c^{kb_2}\) for every \(k \in \mathbb{Z}\). Therefore \(\varphi_1(nb_1 + kb_2) = \varphi_2(0)c^{kb_2}\) for every \(n, k \in \mathbb{Z}\), which yields that \(\varphi_1\) is unbounded on \(I\). As \(I\) was arbitrary, \(\varphi_1\) is unbounded on every subinterval of \(\mathbb{R}\). But \(\varphi_1\) is of Baire class 1, so it has a point of continuity (see e.g. [3, 24.15]), hence it must be bounded on some interval, a contradiction. \(\square\)

**Remark 7.3** The impossibility of (2) is closely related to the well known statement that the identity function is not the sum of two measurable periodic functions (though it is surprisingly the sum of two periodic functions; see e.g. [7] and [5]). Indeed, taking the logarithm of (2), we would obtain a representation of the identity function as the sum of two Baire class 1 periodic functions; the only problem is that our functions can vanish at certain points.

**Theorem 7.4** Let \(D_i f = g_i\ (i \in I)\) be a system of difference equations, and suppose that every difference operator consists of at most two terms; that is for every \(i \in I\) the \(i^{th}\) equation is of the form

\[
a_i^{(1)} f(x + b_i^{(1)}) + a_i^{(2)} f(x + b_i^{(2)}) = g_i(x).
\]

Then if every countable subsystem has a Baire class 1 solution, then the whole system has one as well.
Proof. If any of the equations consists of a single term, then it has a unique solution, so we are clearly done. Thus, by applying a translation and multiplying by a real number, we may assume that every equation is of the form

\[ f(x + b_i) - a_i f(x) = g_i(x). \]

First suppose that \( |a_i|^{1/b_i} \neq |a_i|^{1/b_2} \) for some \( i_1, i_2 \in I \). Then it easily follows from Lemma 7.2 that the two corresponding equations have a unique common Baire class 1 solution. This clearly solves the whole system, as every triple of equations is solvable.

So we can assume that there exists a \( c > 0 \) such that \( |a_i|^{1/b_i} = c \) for every \( i \in I \). If we divide the \( i \)th equation by \( c^{x + b_i} \) and introduce the new unknown function \( \tilde{f}(x) = f(x)/c^x \), and new right hand side \( \tilde{g}_i(x) = g(x)/c^{x + b_i} \), then our equations will attain the form (dropping the tildes) \( \Delta_b f(x) = f(x + b_i) - f(x) = g_i \ (i \in I^-) \) or \( f(x + b_i) + f(x) = g_i \ (i \in I^+) \), where \( I = I^- \cup I^+ \). We put \( B^- = \{ b_i : i \in I^- \} \) and \( B^+ = \{ b_i : i \in I^+ \} \). There are countable subsets \( J^- \subset I^- \) and \( J^+ \subset I^+ \) such that \( E^- = \{ b_i : i \in J^- \} \) is relatively dense in \( B^- \), and \( E^+ = \{ b_i : i \in J^+ \} \) is relatively dense in \( B^+ \).

By assumption, there exists a common Baire class 1 solution \( f \) to the equations with indices \( J^- \cup J^+ \). We claim that \( f \) is a solution to the whole system.

First let \( i \in I^- \). As \( J^- \cup \{ i \} \) is also countable, we can choose a Baire class 1 function \( f^- \) such that \( \Delta_{b_i} f^- = g_j \) for every \( j \in J^- \) and \( \Delta_{b_i} f^- = g_i \). Thus \( f' = f - f^- \). Then for every \( j \in J^- \) we have

\[ \Delta_{b_i} f' = \Delta_{b_i} (f - f^-) = \Delta_{b_i} f - \Delta_{b_i} f^- = g_j - g_j = 0, \]

thus \( f' \) is periodic mod \( b_j \) for each \( j \in J^- \). Let \( G^- = \langle E^- \rangle \); then \( f' \) is periodic mod each element of \( G^- \).

We distinguish between two cases. If \( G^- \) is dense in \( \mathbb{R} \), then \( f' \) must be a constant function \( c \), for otherwise it would attain two distinct values on dense sets, so it would have no point of continuity, which is impossible as \( f' \) is Baire class 1.

Thus

\[ \Delta_{b_i} f = \Delta_{b_i} (f^- + c) = \Delta_{b_i} f^- + \Delta_{b_i} c = g_i + 0 = g_i, \]

which completes the proof in the first case.

If, on the other hand, \( G^- \) is not dense in \( \mathbb{R} \) then \( G^- = \mathbb{Z}d \) for some \( d \in \mathbb{R} \). In particular, \( G^- \) is discrete. Then so is \( E^- \) and thus \( E^- = B^- \) as \( E^- \) is dense in \( B^- \). Since \( b_i \in B^- = E^- \), there is a \( j \in J^- \) with \( b_i = b_j \) which obviously implies \( g_i = g_j \). Therefore, \( f \) satisfies \( \Delta_{b_j} f = \Delta_{b_i} f = g_j = g_i \).

Let now \( i \in I^+ \). Choose a Baire class 1 function \( f^+ \) such that \( f^+(x + b_j) + f^+(x) = g_j(x) \) for every \( j \in J^+ \) and \( f^+(x + b_i) + f(x) = g_i(x) \) for every \( x \in \mathbb{R} \). Put \( f' = f - f^+ \). Then \( f' \) is easily seen to be anti-periodic mod \( b_j \), hence periodic mod \( 2b_j \) for every \( j \in J^+ \), hence it is also periodic mod \( G^+ = \langle \{ 2b_j : j \in J^+ \} \rangle \).

If \( G^+ \) is dense in \( \mathbb{R} \), then \( f' \) must be a constant function \( c \). But \( f' \) is anti-periodic, so \( c = 0 \). Therefore \( f = f^+ \), so \( f \) clearly solves the \( i \)th equation.

On the other hand, if \( G^+ \) is discrete then so is \( E^+ \) and then we can complete the proof as in the previous case. □
Question 7.5 Is it true that $\text{sc}(\{f : f \text{ is Baire class } 1\}) = \omega_1$?

8 Lebesgue and Baire measurable functions

As in Section 5, I shall denote the ideals $\mathcal{N}$ or $\mathcal{M}$. Thus $\mathcal{B}_I$ equals the $\sigma$-algebra of Lebesgue or Baire measurable sets.

The goal of this section is to prove upper and lower estimates for $\text{sc}(\{f : f \text{ is } \mathcal{B}_I\text{-measurable}\})$ in terms of some cardinal invariants of the ideal $\mathcal{I}$. These estimates give the exact value of the solvability cardinal consistently.

Definition 8.1

\[
\text{add}(\mathcal{I}) = \min\{|A| : A \subset \mathcal{I}, \bigcup A \notin \mathcal{I}\}, \\
\text{non}(\mathcal{I}) = \min\{|A| : A \subset \mathbb{R}, A \notin \mathcal{I}\}, \\
\text{cof}(\mathcal{I}) = \min\{|A| : A \subset \mathcal{I}, \forall I \in \mathcal{I} \exists A \in A, I \subset A\}.
\]

Remark 8.2 Note that $\omega_1 \leq \text{add}(\mathcal{I}) \leq \text{non}(\mathcal{I}) \leq \text{cof}(\mathcal{I}) \leq 2^\omega$. The last inequality follows from $\text{cof}(\mathcal{I}) \leq |A|$, where $A = \{B \in \mathcal{I} : B \text{ is Borel}\}$. It is also easy to see that $\text{add}(\mathcal{I}) \leq \text{cf}(\text{non}(\mathcal{I}))$.

Before we prove our estimates (Theorems 8.6 and 8.7) we need some preparation.

Definition 8.3 For a set $H \subset \mathbb{R}$ define

\[D_H = \{D \in \mathcal{D} : D = \sum_{i=1}^n a_iT_{b_i}, b_i \in H \text{ for every } i = 1, \ldots, n\}.
\]

Theorem 8.4 Let $S$ be a solvable system of difference equations and $H \subset \mathbb{R}$. Then $S$ has a solution that is identically zero on $H$ if and only if whenever $(D, g)$ is deducible from $S$ and $D \in D_H$ then $g(0) = 0$.

Proof. The proof is again a variation of the proof of [6, Thm. 2.2].

First suppose that $f$ is a solution to $S$ vanishing on $H$, and let $(D, g)$ be deducible from $S$ such that $D \in D_H$; that is, $D = \sum_{i=1}^n a_iT_{b_i}$, where $b_i \in H$ for every $i$. Then $g(0) = (Df)(0) = \sum_{i=1}^n a_i f(b_i) = 0$, since $b_i \in H$ for every $i$.

Suppose now that whenever $(D, g)$ is deducible from $S$ and $D \in D_H$ then $g(0) = 0$. Let

\[A = \{D \in \mathcal{D} : \exists g (D, g) \text{ is deducible from } S\}.
\]

Then $A$ is a linear subspace of $\mathcal{D}$. Define

\[L(D) = g(0) \quad (D \in A),
\]

where $(D, g)$ is deducible from $S$. To see that $L$ is well defined note that $S$ is solvable, and $Df = g$ whenever $(D, g)$ is deducible from $S$ and $f$ is a solution to
Moreover, each right hand side subsystem of $S$ has a residual set of cardinality at most $|\mathcal{I}| - 1$.

Let $(D, g)$ be a residual (= comeager) set on which $L$ is $I$-measurable. Then there is also one which is zero $I$-a.e. Let $(D, g)$ be a $I$-measurable solution. We have to show that $(D, g)$ solves $S$. First, let $I = \mathcal{N}$ then let $H$ be the set of points of approximate continuity of $f$, while if $I = \mathcal{M}$ then let $H$ be a residual (= comeager) set on which $f$ is (relatively) continuous. Then $\mathbb{R} \setminus H \in I$. It is sufficient to show that there exists a solution to $S$ vanishing on $H$. Using the previous theorem we need to show that if $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$. Let $D = \bigcap_{i=1}^{n} a_iT_{b_i}$, where $b_i \in H$ for every $i$. As $(D, g)$ is $I$-measurable then $g(\mathbb{R}) = 0$.

If $I = \mathcal{N}$ then, using $b_i \in H$, we obtain that $g$ is approximately continuous at 0. If $I = \mathcal{M}$ then, using $b_i \in H$, we obtain that $g$ is (relatively) continuous on the residual set $\bigcap_{i=1}^{n} (H - b_i)$, which contains 0. But in both cases $g = 0$ $I$-a.e., so we obtain $g(0) = 0$ as required.

Theorem 8.5 Let $S$ be a system of difference equations such that for every $(D, g) \in S$ we have $g = 0$ $I$-a.e. If there exists a $\mathcal{B}_{I}$-measurable solution to $S$, then there is also one which is zero $I$-a.e.

Proof. Let $f$ be a $\mathcal{B}_{I}$-measurable solution to $S$. Then $(D, f)$ is $I$-measurable solution if and only if $(D, g)$ is deducible from $S'$. Hence, we have

$$S' = \{(D, g - Df_0) : (D, g) \in S\}.$$
Then $f$ solves $S'$ if and only if it solves $S^*$, moreover, each right hand side of $S^*$ is 0 $\mathcal{I}$-a.e. Also, every subsystem of $S^*$ of cardinality at most $\text{cof}(\mathcal{I})$ has a $\mathcal{B}_\mathcal{I}$-measurable solution since every $(D, g) \in S^*$ is deducible from a finite subsystem of $S'$. In addition, every equation deducible from $S^*$ is already in $S^*$.

Now we prove that $S^*$ has a $\mathcal{B}_\mathcal{I}$-measurable solution, which will complete the proof. By Theorem 8.5, every subsystem of $S^*$ of cardinality at most $\text{cof}(\mathcal{I})$ has an $\mathcal{I}$-a.e. zero solution. We claim that $S^*$ itself has such a solution. Suppose on the contrary that this is not true. Let $A \subset \mathcal{I}$ be such that $|A| = \text{cof}(\mathcal{I})$ and $\forall \mathcal{I} \in \mathcal{I} \exists A \in \mathcal{A}, \mathcal{I} \subset A$. For any $A \in \mathcal{A}$ the system $S^*$ has no solution vanishing outside $A$. By Theorem 8.4 this means that there exists a $(D_A, g_A) \in S^*$ such that $D_A \in \mathcal{D}_{\mathbb{R}\setminus A}$ and $g_A(0) \neq 0$.

The system $\{(D_A, g_A) : A \in \mathcal{A}\}$ is of cardinality $\text{cof}(\mathcal{I})$, hence it has a solution $f$ vanishing $\mathcal{I}$-a.e. Let $A_0 \in \mathcal{A}$ be such that $f$ vanishes outside $A_0$. Then $D_{A_0}f = g_{A_0}$, thus $(D_{A_0}f)(0) = g_{A_0}(0) \neq 0$, but on the other hand $D_{A_0} \in \mathcal{D}_{\mathbb{R}\setminus A_0}$, so $(D_{A_0}f)(0) = 0$. This contradiction finishes the proof. \hfill \Box

**Theorem 8.7** $\text{sc}\{f : f \in \mathcal{B}_\mathcal{I}\text{-measurable}\} \geq \lfloor \text{cof}(\mathcal{I}) \rfloor^+ \geq \lfloor \text{add}(\mathcal{I}) \rfloor^+ \geq \omega_2$.

**Proof.** We have to construct an $S$ with no $\mathcal{B}_\mathcal{I}$-measurable solutions such that each subsystem of cardinality less than $\text{cof}(\mathcal{I})$ has a $\mathcal{B}_\mathcal{I}$-measurable solution.

First we construct a set $B \subset \mathbb{R}$ such that (i) $B \notin \mathcal{I}$, $\mathbb{R}\setminus B \notin \mathcal{I}$, (ii) $|(B + b)\Delta B| < \text{non}(\mathcal{I})$ for every $b \in B$, and (iii) $B \cap (-B) = \emptyset$.

Let $V \subset \mathbb{R}$ be such that $V \notin \mathcal{I}$ and $|V| = \text{non}(\mathcal{I})$. We may assume that $V$ is a linear space over the rationals. Let $\{v_\alpha : \alpha < \text{non}(\mathcal{I})\}$ be a basis of $V$. Represent the nonzero elements of $V$ as $v = \sum_{\alpha=1}^{\alpha} q_i v_{\alpha_i}$, where $q_i \in \mathbb{Q}\setminus\{0\}$ and $\alpha_1 < \ldots < \alpha_\alpha$. Define $\varphi(v) = q_\alpha$, and

$$B = \{v \in V : \varphi(v) > 0\}.$$ 

Clearly, (iii) holds. Note that $V = B \cup (-B) \cup \{0\}$, hence (i) is satisfied. Let $b \in B \setminus \{0\}$ be arbitrary. Suppose $b = \sum_{i=1}^{\alpha} q_i v_{\alpha_i}$, where $q_i \in \mathbb{Q}\setminus\{0\}$ and $\alpha_1 < \ldots < \alpha_\alpha$. Then $(B + b)\Delta B$ is included in the linear space generated by $\{v_\alpha : \alpha \leq \alpha_\alpha\}$, which is of cardinality less than $\text{non}(\mathcal{I})$. So (ii) holds as well.

We claim that the system

$$S = \{\Delta_b, \Delta_b \chi_B : b \in B\}$$

satisfies the requirements. First we check that each right hand side is zero $\mathcal{I}$-a.e. Indeed, if $b \in B$ then $\{x \in \mathbb{R} : (\Delta_b \chi_B)(x) \neq 0\} \subset (B + b)\Delta B \in \mathcal{I}$, since $|(B + b)\Delta B| < \text{non}(\mathcal{I})$.

Suppose that $S$ has a $\mathcal{B}_\mathcal{I}$-measurable solution. Then, by Theorem 8.5, $S$ has an $\mathcal{I}$-a.e. zero solution $f_0$ as well. Then $\Delta_b f_0 = \Delta_b \chi_B$ for every $b \in B$, so $f_0 - \chi_B$ is periodic mod every $b \in B$. Then it is also periodic mod each $b \in -B$. In particular, $f_0 - \chi_B$ is constant on $B \cup (-B)$. But $f_0 = 0$ $\mathcal{I}$-a.e., $B \notin \mathcal{I}$, and $B \cap (-B) = \emptyset$ which is impossible.
What remains to show is that each subsystem $S'$ of $S$ of cardinality less than $\text{cf}(\non(I))$ has a $\mathcal{B}_I$-measurable solution. Let $B'$ be the corresponding subset of $B$, where $|B'| < \text{cf}(\non(I))$. Now we put

$$A = (B') + \bigcup_{b' \in B'} [(B + b') \Delta B].$$

Then $|A| < \non(I)$, hence $A \in I$. It is easy to see, by checking the cases $x \in A$ and $x \notin A$, that $f = \chi_{B \cap A}$ is a $\mathcal{B}_I$-measurable solution to $S'$. \hfill \Box

**Corollary 8.8** The Continuum Hypothesis implies

$$\text{sc}(\{f : f \text{ is measurable}\}) = \text{sc}(\{f : f \text{ has the Baire property}\}) = \omega_2 = (2^{\omega})^+.$$

**Question 8.9** Is $\text{sc}(\{f : f \text{ is } \mathcal{B}_I \text{-measurable}\})$ equal to $[\text{cof}(I)]^+$? Is $\text{sc}(\{f : f \text{ is } \mathcal{B}_I \text{-measurable}\})$ equal to $[\text{cf}(\non(I))]^+$?
