(Dated: February 19, 2021)

We theoretically show that the dynamics of a driven quantum harmonic oscillator subject to non-dissipative noise is formally equivalent to the single-particle dynamics propagating through an experimentally feasible dynamically-disordered photonic network. Using this correspondence, we find that noise assisted energy transport occurs in this network and, if the noise is Markovian or delta-correlated, we can obtain an analytical solution for the maximum amount of transferred energy between all network’s sites at a fixed propagation distance. Beyond the Markovian limit, we further consider two different types of non-Markovian noise and show that it is possible to have efficient energy transport for larger values of the dephasing rate.

I. INTRODUCTION

From a practical point of view, decoherence (the irreversible loss of quantum coherence) is a multifaceted process which presents advantages and disadvantages depending on the particular circumstances and application. For instance, from the perspective of perfect state transport, decoherence is the opponent to overcome since it may destroy the states way before they can be conveyed [1]. On the contrary, to perform highly-efficient energy transport protocols, decoherence has been found to be the best allied [2, 3]. Thus, a good understanding of the impact of decoherence on energy transport and energy conversion in the quantum and classical regimes is essential to design functional technologies based on hybrid systems [4], ranging from quantum information processing tasks to quantum thermodynamics applications [5–8].

In optics, one can use integrated photonic devices, e.g., based on direct laser-writing coupled waveguides lattices [9, 10], to study coherent energy transport [11–13], which is an important ingredient in the development of integrated photonic quantum technologies [14, 15]. Such devices constitute a well-established, popular and relatively low-cost platform among experimentalists due to their practical fabrication process, where their physical and novel geometric properties can be easily tailored [16]. In general, these devices are never completely isolated from their environment, therefore to describe their energy losses and decoherence processes, a treatment based on the theory of open or stochastic quantum system [17] is needed.

In the present work, we study coherent and incoherent energy transport in a particular type of integrated photonic device termed Glauber-Fock (GF) photonic lattice [18, 19]. We choose this particular photonic structure because its closed dynamics is effectively described by the unitary evolution of a displaced quantum harmonic oscillator [18], as experimentally demonstrated in [20, 21]. In addition, physics of nonlinear [22] and non-Hermitian systems [23, 24] can also be studied using such photonic devices. Thus far, there is a lack of theory accounting for the interaction of GF lattices with non-dissipative noisy environments. Here, we close this gap by considering specific instances of Markovian (white) and non-Markovian (correlated) noise. Further, we show that the corresponding open system dynamics is equivalent to that of a single-excitation propagating in a dynamically-disordered network. Such noisy scenarios are quite relevant in integrated photonics. For example, the interplay between noise and interference effects can lead to a faster transmission in the transport dynamics of integrated photonic mazes [25] or enhancing the coherent transport using controllable decoherence [12]. Our results also present a clear manifestation of the so-called environment-assisted transport phenomenon in the single-excitation regime [2, 3, 26–28]. Furthermore, we observe that non-Markovianity in the dynamics of the system enhances the range of dephasing rates over which this effect persists in our model.

The paper is structured as follows. In sections II and III we analytically show that the master equation governing the closed and open dynamics of a single excitation in a GF lattice is identical to the one describing the evolution of a driven quantum harmonic oscillator. We then examine the impact of non-dissipative Markovian noise on the energy transport. In section IV we explore non-Markovian noise models, while in section V we discuss the usefulness of having a correspondence between the master equations of a driven harmonic oscillator and a single particle propagating in a GF lattice.
In particular, when the noise-assisted energy transport phenomenon is manifested in the Markovian case, it is possible to find an analytical solution for the maximum amount of energy transferred between all sites of the photonic network. This constitutes one of the main results of the present work and provides clear advantage in energy transport calculations. For the non-Markovian case, we find a substantial increase in the range of the dephasing rate for which the noise-assisted transport takes place, indicating that the common idea [29] that noise-assisted transport occurs only in the moderate decoherence regime is no longer accurate when the environment’s finite correlation time is considered. In section VI we draw our conclusions.

II. THE GLAUBER-FOCK OSCILLATOR MODEL

We start by introducing the Hamiltonian of the quantum harmonic oscillator (HO) in one-dimension driven by an external perturbation \( \hat{H} = \hbar \omega \hat{n} + h g (\hat{a} + \hat{a}^\dagger) \) [30]. Here, \( \hat{a} \) and \( \hat{a}^\dagger \) are the usual annihilation and creation operators, \( \hat{n} = \hat{a}^\dagger \hat{a} \) is the number operator, and \( \omega \) is the oscillator frequency. The term \( h g (\hat{a} + \hat{a}^\dagger) \) represents a displacement with strength \( g \). In the field of integrated photonics, this Hamiltonian governs the light dynamics in the so-called Glauber-Fock (GF) lattice [18, 20, 21] or GF oscillator.

A. Unitary dynamics in GF lattices

Assume that the state of the driven HO is given by \( |\Psi(t)\rangle = \sum_m A_m(t) |m\rangle \), with \( |m\rangle \) being the energy eigenstates and \( A_m(t) \) are the corresponding probability amplitudes. Then, it is possible to show that the equations of motion for \( A_m(t) \), dictated by the time-dependent Schrödinger equation \( i \hbar \frac{d}{dt} |\Psi(t)\rangle = \hat{H} |\Psi(t)\rangle \) with the above-mentioned Hamiltonian, are isomorphic to the ones describing the dynamics of a mode field amplitude, \( \mathcal{E}_m(z) \), propagating in a high-quality optical waveguide that is coupled evanescently to its nearest neighbors forming a semi-infinite photonic lattice given as [21]

\[
\frac{d}{dz} \mathcal{E}_m(z) + C_m \mathcal{E}_{m-1}(z) + C_{m+1} \mathcal{E}_{m+1}(z) + \alpha m \mathcal{E}_m(z) = 0,
\]

where \( z \) represents the propagation coordinate, \( C_m \equiv C_1 \sqrt{m} \) the non-uniform coupling coefficients with \( C_1 \) being the coupling between the zeroth and the first waveguide and \( \alpha m \) are the propagation constants. Importantly, in the context of photonic lattices, the term \( \alpha m \) implies that the refractive index of the waveguides describes a potential that is gradually increasing (for \( \alpha > 0 \)) with the waveguide number. That is, the potential describes a ramp, whose slope is controlled by the parameter \( \alpha \), see Fig. 1 of [21] for an illustration of this refractive index profile. In a GF lattice \( \alpha \) can also be negative, generating a different lattice response. However, throughout this work we assume that \( \alpha \) is always positive. The correspondence between Eq. (1) with the equations of \( A_m(t) \) can be established if we identify the label “\( m \)” of each excited waveguide with the corresponding Fock state \( |m\rangle \), \( C_1 \) with \( g \), \( \alpha \) with \( \omega \) and the propagation coordinate \( z \) with the time variable \( t \) [31].

&\text{(b)} \\
&\text{(c)} \\
&\text{(d)} \\
&\text{(e)} \\
&\text{(f)}
\end{align*}

FIG. 1. Light intensity propagation in a photonic lattice obtained by integrating Eq. (1). Light is initially launched into a single waveguide labeled as \( m = 0 \) (a), (b) and \( m = 2 \) (c), (d). In (e), (f) we show the output light intensity \( I_m(Z) = |\mathcal{E}_m(Z)|^2 \) at \( Z = 3\pi/2 \) for the simulations presented in (b), (d), respectively. Note, \( Z \equiv C_1 Z \) is the scaled propagation distance. \( I_m(Z) \) exhibits \( m \) nodes as expected from to the probability distribution of the non-classical displaced Fock states [20]. When the ramping potential is activated, \( \alpha \neq 0 \), we see Bloch-like oscillations [32] (left), where the light exhibits revivals every period \( T_{rev} = 2\pi C_1 / \alpha \) with \( k \) being an integer [21]. We have set the ratio \( \alpha/C_1 = 1/2 \) in (a), (c) and \( \alpha/C_1 = 0 \) in (b), (d), which are feasible experimental values that would allow us to implement realistic integrated photonic devices occupying few centimeter-scale footprints, see the text for more details.
which it strongly localizes as a manifestation of the so-called Bloch-like oscillations [32]. The analytical solution of Eq. (1) can be found in Ref. [21] in terms of the associated Laguerre polynomials. As a function of the scaled (or normalized) distance \( Z \equiv C_1 z \), the behavior of \( E_m(Z) \) simply depends on the ratio \( \alpha / C_1 \), and the so-called revival distance \( Z_{\text{rev}} \) is given as \( Z_{\text{rev}} = 2\pi kC_1 / \alpha \). Note that the difference in the case \( \alpha > C_1 \) as compared to \( \alpha < C_1 \) is the period of the Bloch-like oscillations, which is short in the former case. Here, to be in accordance with the reported experimental values of \( \alpha \) and \( C_1 \) in previous works, we adopt the latter case. These are simple examples showing the typical dynamics of coherent energy transport in closed systems where strong interference effects dominate. However, when dynamical disorder mechanisms are considered in an open system description, a more involved study of the incoherent energy transport dynamics is necessary, which we aim to cover in the following sections.

B. Open dynamics: Markovian master equation

Under the action of Markovian dephasing the density matrix \( \rho \) of the harmonic oscillator described by the Hamiltonian \( \hat{H} = \hbar \omega \hat{n} + h g (\hat{a} + \hat{a}^\dagger) \) obeys the phenomenological master equation \( d\hat{\rho} / dt = -i[\hat{H}, \hat{\rho}] + \gamma \hat{L}[\hat{n}] \hat{\rho} \). Here the second term on the right hand side is the standard Lindblad superoperator given by \( \hat{L}[\hat{n}] \hat{\rho} \equiv \hat{x} \hat{x}^\dagger - \frac{1}{2} \{ \hat{x}^\dagger \hat{x} \hat{\rho} + \hat{\rho} \hat{x}^\dagger \hat{x} \} \) with \( \gamma \) being the constant dephasing rate. This master equation can be derived using standard techniques of open quantum systems, where the usual Born and Markov approximations are used [17].

In general, pure dephasing processes are energy preserving [33], as a result, the interaction between the system and its environment commutes with the unperturbed Hamiltonian of the system, \( \omega \hat{n} \) in the present case. To obtain the master equation we compute the matrix elements \( \langle n | \hat{H} | m \rangle = \omega n \rho_{nm} + \sum_r g V_{nm} \rho_{nr} \) with \( V_{nm} = \langle r | (\hat{a} + \hat{a}^\dagger) | m \rangle = (\sqrt{m} \delta_{nm-1} + \sqrt{m+n} \delta_{nm+1}) \), a similar expression is obtained for \( \langle n | \hat{\rho} \hat{H} | m \rangle \). The matrix elements for the dephasing term are

\[
\gamma \langle n | \hat{L}[\hat{n}] | m \rangle = \sqrt{\gamma n} \sqrt{\gamma m} \rho_{nm} - \rho_{nm} (\gamma n^2 + \gamma m^2 / 2). \tag{2}
\]

Therefore, we obtain

\[
i \frac{d}{dt} \rho_{nm} = \left( (\omega n - \omega m) - \frac{i}{2} (\gamma n^2 + \gamma m^2) \right) \rho_{nm} + i \sqrt{\gamma n} \sqrt{\gamma m} \rho_{nm} - \sum_r g V_{nm} \rho_{nr} + \sum_r g V_{nr} \rho_{rn}. \tag{3}
\]

Defining the variables \( \omega_n \equiv n \omega, \gamma_n \equiv \gamma n^2 \) and \( v_{ij} \equiv g V_{ij} \), we can rewrite Eq. (3) as

\[
i \frac{d}{dt} \rho_{nm} = \left( (\omega_n - \omega_m) - \frac{i}{2} (\gamma_n + \gamma_m) \right) \rho_{nm} + i \sqrt{\gamma_n} \sqrt{\gamma_m} \rho_{nm} - \sum_r v_{nm} \rho_{nr} + \sum_r v_{rn} \rho_{rm}. \tag{4}
\]

which is the same master equation that a single particle, or excitation, follows during its time evolution in a quantum network affected by non-dissipative noise, as we show in the following section (see also Eq. (1) of Ref. [34]). Since Eq. (4) describes a pure-dephasing process only the off-diagonal matrix elements of \( \rho \) are affected by the constant dephasing rate \( \gamma \). Notice that the form of \( \gamma_n \equiv \gamma n^2 \) implies that Fock states with high \( n \) are more severely affected by dephasing.

III. SINGLE-PARTICLE DYNAMICS IN A NETWORK AFFECTED BY MARKOVIAN NOISE

In this section, we show the equivalence between Eq. (3) [or alternatively Eq. (4)] and the master equation governing the evolution (or propagation) of a single particle in a tight-binding quantum network composed of \( N \) coupled sites affected by a stochastic non-dissipative noise (pure dephasing). In the following and throughout the whole paper, keep in mind that with the correspondence between the spatial (\( z \)) and temporal (\( t \)) variables, the integrated photonic lattices discussed in the previous section would be a particular case of such networks. In order to establish this connection we begin by writing the single-particle tight-binding Hamiltonian

\[
\hat{H}_S = \sum_{n=1}^{N} \omega_n(t) | n \rangle \langle n | + \sum_{j<n}^{N} \kappa_{nj} (| j \rangle \langle n | + | n \rangle \langle j |),
\]

such that the evolution of the single-particle wavefunction, \( \psi_n \), at the \( n \)th site is governed by the stochastic Schrödinger equation

\[
\frac{d\psi_n}{dt} = -i \omega_n(t) \psi_n - i \sum_{j \neq n} \kappa_{nj} \psi_j, \tag{6}
\]

where \( \kappa_{nj} \) represents, in principle, an arbitrary hopping rate between sites \( n \) and \( j \). \( \omega_n(t) = n(\omega + \phi_n(t)) \) is the frequency at the \( n \)th site that is affected by the random fluctuations \( \phi_n(t) \). Note each site exhibits a different natural frequency that changes linearly with \( n \), namely \( \omega_n \). In most of the literature dealing with stochastic quantum networks all sites have the same frequency. However, since our main goal is to establish a connection between the present physical setting and the one describing a driven HO, outlined in Sec. II B, we chose the frequency of the \( n \)th site to be proportional to \( n \). To introduce pure dephasing we consider \( \phi_n(t) \) to be a Gaussian stochastic process with a zero mean, \( \langle \phi_n(t) \rangle = 0 \), and two-point correlation function given as

\[
\langle \phi_n(t) \phi_m(t') \rangle = \Gamma \delta_{nm} \delta(t-t'), \tag{7}
\]

where \( \Gamma \) is the noise strength (dephasing rate) that we have assumed to be the same for all sites. The Kronecker delta \( \delta_{nm} \) implies that the noise is uncorrelated between sites \( n \) and \( m \), the Dirac delta function \( \delta(t-t') \) describes the Markovian nature (white noise) of the stochastic process, and \( \langle \ldots \rangle \) denotes the average over all possible noise...
realizations. Next, following Ref. [35] we derive the corresponding master equation for the density matrix

\[ i \frac{d}{dt} \sigma_{nm} = [(\omega_n - \omega_m) - \frac{i}{2}(\Gamma_n + \Gamma_m)]\sigma_{nm} \]

\[ + i \sqrt{\Gamma_n \Gamma_m} \delta_{nm} \rho_{nm} - \sum_j \kappa_{jm} \sigma_{nj} + \sum_j \kappa_{nj} \sigma_{jm}, \]  

where \( \sigma_{nm}(t) \equiv \langle \psi_n \psi_m^* \rangle \), see appendix A. Adopting the notation, \( \omega_n = n\omega \) and \( \Gamma_n = \Gamma n^2 \), we obtain

\[ i \frac{d}{dt} \sigma_{nm} = [(\omega_n - \omega_m) - \frac{i}{2}(\Gamma_n + \Gamma_m)]\sigma_{nm} \]

\[ + i \sqrt{\Gamma_n \Gamma_m} \delta_{nm} \rho_{nm} - \sum_j \kappa_{jm} \sigma_{nj} + \sum_j \kappa_{nj} \sigma_{jm}. \]  

Notice that the only difference between Eq. (9) and Eq. (4) is the Kronecker delta \( \delta_{nm} \) appearing in the second term on the right-hand-side of Eq. (9). This difference emerges from the fact that we have assumed no correlation between noise affecting different sites, see Eq. (7). However, Eq. (4) and Eq. (9) become identical (no Kronecker delta in Eq. (9)) if we assume \( \langle \phi_n(t) \phi_m(t') \rangle = \Gamma \delta(t - t') \), i.e., there must be a correlation between stochastic processes at different sites. Such correlation condition, which at first glance seems unlikely to achieve in practice, can easily be emulated using laser written photonic lattices in which temporal correlations are translated into longitudinal spatial correlations.

In these photonic devices, ultra-short laser pulses are used to inscribe each waveguide (site) with a customized refractive index (propagation constant or site energy) depending on the writing speed [34]. The random fluctuations (noise) in the refractive index are implemented by modulating the laser’s writing speed during the manufacturing process with a high degree of control, keeping the coupling coefficients unchanged [25]. Contrary to uncorrelated noise (7), where independent noise generators in each inscribed waveguide are used [25, 34], for correlated noise between sites (\( \delta_{nn} = 1 \)), a single generator would need to be used during each fabrication step of the waveguide array.

Let us emphasize that in GF lattices, the hopping rates must satisfy, as in the previous case, \( \kappa_{nj} = g(\sqrt{\delta_{nj}} - 1 + \sqrt{1 + \Gamma \delta_{nj+1}}) \) and the time evolution must be interpreted as spatial propagation. The light intensity represents the probability distribution \( P_n \) but now this is given by the diagonal matrix elements \( \rho_{nn} \) and \( \sigma_{nn} \).

In Fig. (2) we compare the dynamics generated by numerically integrating Eq. (9) and Eq. (4). Specifically, we present the corresponding diagonal elements, \( \sigma_{nn} \) and \( \rho_{nn} \), to illustrate the intensity propagation in a dynamically disorder Glauber-Fock photonic lattice. Both master equations were numerically solved using the technique described in [36]. In Fig. (2) one can see that due to the added noise, near the revival distances \( C_1 z_{rev} = 4 \pi \kappa \) light delocalization is more prominent. From the experimental point of view this means that one could build photonic waveguide arrays having just one Bloch-like oscillation (\( k = 1 \)) and see the desired dephasing effect. In fact, the ratio \( \alpha/C_1 = 1/2 \) used in Figs. (1) and (2) can easily be obtained by choosing the coupling between the zeroth and the first waveguide as \( C_1 = 0.88 \text{cm}^{-1} \) [37, 38] and \( \alpha = 0.044 \text{mm}^{-1} \) [32]. The use of these values implies that we should design approximately 40 nearest-neighbor coupled waveguides with \( z_{rev} = 4 \pi /C_1 = 14.28 \text{cm} \), which is a feasible scenario. For instance, in [11, 12, 20, 21, 39] waveguides arrays of 10cm to 15cm long were built, and in [37, 38], 101 identical waveguides were inscribed within one of these types of arrays. In the photonic device, the parameter \( C_m = C_1 \sqrt{m} \) increases with the waveguide’s label, and by using the above parameters we obtain \( C_{40} \approx 5.5 \text{cm}^{-1} \), which corresponds to the largest coupling coefficient reported experimentally in [40]. It is worth pointing out that, given the stochastic nature of the process, a certain number of waveguide samples is needed in order to observe the mean density matrix described in Eq. (9). Previous work by two of us [34] has shown that this number is approximately 20. We would also like to mention that reconfigurable electrical oscillator networks [27, 41] and optical tweezer arrays [42, 43] are other viable experimental platforms in which Eq. (9) and the correlated noise condition between different sites can be realized.
IV. TIME-DEPENDENT DEPHASING RATE IN THE MASTER EQUATION

We now turn our attention to generalize the results obtained in the previous section to the case of time-dependent dephasing. This opens up the possibility to introduce memory effects in the dynamics of both models, that is, it enables investigations of non-Markovian effects.

A. Glauber-Fock oscillator

The master equation, in the Lindblad form, for the Hamiltonian $\hat{H}$ under a time-dependent dephasing noise is given as

$$\frac{d\hat{\rho}}{dt} = -i[\hat{H}, \hat{\rho}] + \gamma(t)\hat{L}[\hat{n}]\hat{\rho}. \quad (10)$$

This equation is an ad hoc generalization of the master equation of a two-level system describing pure-dephasing dynamics in a possibly non-Markovian regime (see Eq. (9) of Ref. [44] and Eq. (17) of Ref. [45]). In cases where $\gamma(t)$ becomes negative, the quantum dynamical semigroup property of Eq. (10) no longer holds [17]. Consequently, the divisibility of the quantum map is broken and Eq. (10) can be classified as non-Markovian [45, 46]. Here, we only consider cases in which $\gamma(t)$ is non-negative. However, it is worth pointing out that Eq. (10) can be used to describe the dynamics of the system under non-Markovian environments provided the dephasing rates exhibit finite environment correlation times [44, 47].

From Eq. (10), and following the same steps as in the previous section, we obtain the master equation

$$i\frac{d}{dt}\rho_{nm} = \left[(\omega_n - \omega_m) - \frac{i}{2}(\gamma_n(t) + \gamma_m(t))\right]\rho_{nm}$$

$$+ i\sqrt{\gamma_n(t)}\gamma_m(t)\rho_{nm} - \sum_r \kappa_{rn}\rho_{nr} + \sum_r \kappa_{nr}\rho_{rm}. \quad (11)$$

It is interesting to note that the only difference between this expression and Eq. (4) is the time-independent $\gamma_n$ which is now replaced by $\gamma_n(t) \equiv \gamma(t)n^2$. In what follows, we discuss its effect in the transport dynamics of complex quantum networks.

B. Single-particle dynamics in a quantum network

We start by investigating the dynamics of a single particle under the influence of a Gaussian non-Markovian stochastic noise $\Omega_n(t)$, with zero mean $\langle \Omega_n(t) \rangle = 0$ and two-point correlation function

$$2\langle \Omega_n(t)\Omega_m(t') \rangle = \Gamma\delta_{nm}e^{-\lambda|t-t'|}. \quad (12)$$

This is the well known modified Ornstein-Uhlenbeck noise (OUN), where $\Gamma$ is the inverse relaxation time and $\lambda$ is the noise bandwidth which is related to the environmental memory time in the following way $\tau_c = \lambda^{-1}$, such that when $\lambda$ is finite the $\tau_c$ is also finite giving a non-Markovian character to the dynamics (see Eq. (3) of [44] and Eq. (2.9) of Ref. [47] for a detailed discussion on OUN). This process has a well defined Markovian limit which is obtained when $\lim_{\lambda \to \infty}\langle \Omega_n(t)\Omega_m(t') \rangle = \Gamma\delta_{nm}\delta(t-t')$ [44].

As shown in appendix A, for the present case we obtain the equation

$$\frac{d}{dt}\sigma_{nm} = -i(n\omega - m\omega)\sigma_{nm} - i\sum_{j\neq n}\kappa_{nj}\sigma_{jm}$$

$$+ i\sum_{j\neq m}\kappa_{jm}\sigma_{nj} - in\langle \psi_n\psi_m^*\Omega_n(t) \rangle + im\langle \psi_n\psi_m^*\Omega_m(t) \rangle, \quad (13)$$

where the matrix elements are given as $\sigma_{nm} = \langle \psi_n\psi_m^* \rangle$. Although $\Omega_n(t)$ represents in general non-Markovian noise it is still a Gaussian process, therefore, we can use the Novikov’s theorem [48] to compute the elements

$$\langle \psi_n\psi_m^*\Omega_n(t) \rangle \approx -\frac{i}{2}n\sigma_{nm}(t)\Gamma(t) + \frac{i}{2}m\delta_{nm}\sigma_{nm}(t)\Gamma(t), \quad (14)$$

where $\Gamma(t) \equiv (1 - e^{-\lambda t})/2$, is, basically, the time integral of the two-point correlation function of the environment [44], see appendix B for details. Hence, Eq. (13) becomes

$$i\frac{d}{dt}\sigma_{nm} = \left[(\omega_n - \omega_m) - \frac{i}{2}(\Gamma_n(t) + \Gamma_m(t))\right]\sigma_{nm}$$

$$+ i\sqrt{\Gamma_n(t)\Gamma_m(t)}\delta_{nm}\sigma_{nm} - \sum_r \kappa_{rn}\sigma_{nr} + \sum_r \kappa_{nr}\sigma_{rm}. \quad (15)$$

where $\Gamma_n(t) \equiv \Gamma(t)n^2$. This is the master equation and describes the dynamics of a single particle in a non-Markovian environment and, as expected, it reduces to Eq. (9) when $\Gamma(t)$ is time-independent.

Similarly to the case of Markovian noise, discussed in the previous section, the only difference between Eq. (15) and Eq. (11) is the additional Kronecker delta appearing in Eq. (15). That is, when there are noise correlations between different sites then $\rho_{nm}$ and $\sigma_{nm}$ become identical. Even though they exhibit similar evolution, $\rho_{nm}$ and $\sigma_{nm}$ are of a different nature. In other words, $\rho_{nm}$ is the density matrix for a quantum harmonic oscillator inhabiting in an infinite dimensional Hilbert space spanned by an infinite number of Fock states. In contrast, $\sigma_{nm}$ is the density matrix of a single particle, or excitation, evolving in a quantum network made out of finite number of coupled sites, with their corresponding Hilbert space.

Finally, we would like to stress that the derivation of Eqs. (9) and (15) is, in principle, valid for arbitrary time-independent hopping rates $\kappa_{rn}$ and not only for nearest-neighbor interactions. Therefore, these master equations may describe an extensive class of complex networks that do not necessarily have to be photonic.
V. AVERAGE ENERGY OF THE SYSTEM

A. Analytical solution for the Markovian case

In this section we discuss some advantages of having a correspondence between the master equations of a driven quantum harmonic oscillator and a single particle propagating in a photonic network. When one is interested in computing the average of certain observables, e.g. the average energy of a particle propagating in a network, solving the HO master equation is much simpler than solving the latter. For example, if we insert the Hamiltonian describing the Glauber-Fock oscillator \( \hat{H}_G = \omega \hat{n} + (\hat{a} + \hat{a}^\dagger) \) into Eq. (10), we readily obtain the equations of motion for the average of the number and field operators

\[
\frac{d\langle \hat{n} \rangle}{dt} = -ig\langle \hat{a}^\dagger \rangle + ig\langle \hat{a} \rangle, \quad \frac{d\langle \hat{a} \rangle}{dt} = (-i\omega - \gamma(t))\langle \hat{a} \rangle - ig,
\]

where \( d\langle \hat{a}^\dagger \rangle/dt = d\langle \hat{a} \rangle^*/dt \). In the absence of dephasing, \( \gamma(t) = 0 \), and assuming the initial condition \( |\psi(0)\rangle = |m\rangle \), these equations reduce to the well-known solution for the average of the number operator \( \langle \hat{n}(t) \rangle = m + (2g/\omega)^2\sin^2(\omega t/2) \). From this expression, one can directly determine the time at which the states return to its initial configuration (revival time) \( T_{\text{rev}} = 2\pi k/\omega \), with \( k \) being an integer. Further, in the limit \( \omega \to 0 \), the evolution operator becomes the Glauber displacement operator, \( D(\alpha) = \exp(\alpha \hat{a} - \alpha^* \hat{a}^\dagger) \) with \( \alpha =igt \), that transforms a vacuum initial state into a coherent state [20]. Accordingly, in this limit we have \( \lim_{\omega \to 0} \langle \hat{n}(t) \rangle \sim (gt)^2 \), which corresponds to the average value of a coherent state. For the case of non-dissipative (pure dephasing) Markovian noise the dephasing rate is a non-negative constant \( \gamma \neq 0 \). Then, the average for the number operator is

\[
\langle \hat{n}(t) \rangle = m + \frac{2g^2}{(\omega^2 + \gamma^2)^2} (f(t) + e^{-\gamma t} g(t)),
\]

where we have defined the functions \( f(t) \equiv \gamma^2/(\gamma t - 1) + \omega^2(\gamma t + 1) \) and \( g(t) \equiv (\gamma^2 - \omega^2)\cos(\omega t) - 2\gamma^2\omega \sin(\omega t) \). It is remarkable that the temporal behavior of \( \langle \hat{n}(t) \rangle \) in the quantum system gives crucial information about the energy transport across all sites in the photonic structure at fixed propagation distance [31]. This is because \( \langle \hat{n}(t) \rangle \) can be rewritten as \( \langle \hat{n}(t) \rangle = \sum_n P_n(t)n \), where \( P_n(t) = \rho_{nn}(t) \) is the probability distribution that we are associating with the light intensity \( I_n(z) \) on each waveguide of the photonic lattice. So, in GF lattices, \( I_n(z) \) is measured first and then the quantity \( \langle \hat{n}(z) \rangle_{\text{class}} = \sum_{m=0}^M mI_m(z) \) is evaluated. This corresponds to the classical analog of the average photon number in waveguide arrays. Evaluating \( \langle \hat{n}(t) \rangle \) at the revival time (revival distance in the GF lattice) yields

\[
\langle \hat{n}(T_{\text{rev}}) \rangle = m + \frac{2g^2}{\omega^2} \left[ \frac{2\pi k_{\gamma}}{1 + \gamma^2} + \frac{1 - \gamma^2}{(1 + \gamma^2)^2} \right] (1 - e^{-2\pi k_{\gamma}}),
\]

where \( \gamma = \gamma/\omega \) is the scaled dephasing rate and \( m \) is the initially excited site. Note \( \langle \hat{n}(T_{\text{rev}}) \rangle \) attains its maximum value when the decoherence rate is comparable to the energy scale of the system, i.e., when \( \gamma \sim 1 \) Eq. (18) reduces to \( \langle \hat{n}(T_{\text{rev}}) \rangle_{\text{max}} \sim m + 2\pi k (g/\omega)^2 \). This result indicates that independently of the initial condition (excited site) \( |m\rangle \), the delocalization of the initial excitation will increase linearly, as a function of \( k \), at each revival time (distance) as shown in Fig. (3).

The Bell-like shape depicted in Fig. (3) is in fact a signature of the so-called environment assisted transport phenomenon, which in the present case is symmetric with respect to the scaled dephasing rate. Note that this result contrasts with the asymmetric behavior typically observed in other coupled-oscillator systems [26, 31, 49].

In general, there are two distinct regimes in systems exhibiting noise-assisted transport. For small dephasing rate, \( \gamma \ll 1 \), the energy transport is proportional to \( \gamma \), such that Eq. (18) reduces to \( \langle \hat{n}(T_{\text{rev}}) \rangle \sim m + 4\pi k (g/\omega)^2 \gamma^2 \). On the other hand, when the dephasing rate is very high, \( \gamma \gg 1 \), the energy transport decreases with \( 1/\gamma \), in fact, it is easy to show that \( \langle \hat{n}(T_{\text{rev}}) \rangle \sim m + 4\pi k (g/\omega)^2 \gamma^{-1} \). These regimes are shown in Fig. (4), see black solid lines. The fact that the energy transport has a nonmonotonic behavior can be understood, in a quantum scenario, as a consequence of the quantum Zeno effect (QZE) [50]. In the QZE a frequent measurement on a quantum system inhibits transitions between quantum states [51]. In our system the QZE is dominant when the dephasing rate is extremely high, i.e. when the non-dissipative noise acts as the measurement process.

In the corresponding optical context of waveguide arrays, the above effects are expected to occur at the revival distance, under the assumptions of couplings coefficients without disorder and no losses in the waveguide array. However, that is not the case in practical implementations. For example, in the presence of static disorder Anderson localization of light will occur for large
disorder values as experimentally demonstrated in [38] for \( \alpha = 0 \), i.e., without Bloch oscillations. When static disorder and Bloch oscillations are both present, Hybrid Bloch-Anderson localization of light emerges with gradual washing out of Bloch oscillations [39]. Nevertheless, in such case, the first Bloch-like revival (the one we have required to be present in this work) is still visible [39]. Hence, we deduce that our results are robust against static disorder. On the other hand, a typical experiment of this kind shows low losses. To be more specific, propagation losses are in the range of 0.1–0.9dB cm\(^{-1}\) for straight sections of the waveguides and also there is an excellent mode overlap with standard fibers (0.1 dB cm\(^{-1}\)) [10, 16, 34]. Moreover, losses are approximately independent of the writing speed [9].

Before concluding this subsection, we would like to point out that while we have assumed zero temperature conditions for the driven quantum harmonic oscillator, there is no restriction for considering temperature effects upon the photonic lattices structures. Most experiments using direct laser-written waveguides are performed at room temperature [9, 10]. Moreover, impressive thermal effects can be admitted on these devices. For instance, in [52], it was experimentally shown that varying a temperature gradient, the Bloch oscillations’ period and amplitude could be controlled. This can be done by heating and cooling the opposite sides of the waveguide array. Specifically, a transverse linear temperature gradient \( \Delta T \) leads to a linear variation of the propagation constants, i.e., \( \alpha \propto \Delta T \). Such result suggests an attractive alternative to get the desired ramp potential or the random fluctuations without changing the laser’s writing speed.

### B. Numerical solution for the non-Markovian case

We now look into the numerical solutions of the equations of motion for the average field and number operators under two different types of non-Markovian noise models. We consider Ornstein-Uhlenbeck noise (OUN) and power law noise (PLN), both of which have a well defined Markovian limit. The time-dependent dephasing rates for these cases are given as [47, 53]

\[
\Gamma(t) = \begin{cases} 
\frac{\Gamma}{2}(1-e^{-\lambda t}) & \text{OUN}, \\
\frac{\Gamma}{2(\lambda+1)^2} & \text{PLN}, 
\end{cases}
\]

(19)

where \( \Gamma \) is the inverse relaxation time and \( \lambda \) and \( 1/\lambda \) are the noise bandwidths for OUN and PLN, respectively, which in turn are related to the finite correlation time of the environment. Note these quantities can be considered as the inverse environmental memory time that vanishes in the limit of \( \lambda \to \infty \) and \( 1/\lambda \to \infty \) for OUN and PLN, respectively, yielding the Markovian limits of these noise models. Naturally, in the Markovian limit, the time-dependent dephasing factors become time-independent. It is important to note that in both cases \( \Gamma(t) \) never becomes negative throughout the evolution. Therefore, the dynamics generated are CP-divisible at all times and considered as Markovian [54, 55]. Nevertheless, it is clear that finite environment correlation time results in non-Markovian behavior in the dynamics [44, 47], such that any intermediate map taking the system from \( t_1 \) to \( t_2 \), is not independent of the initial time \( t_0 \). It has been shown that it is also possible to quantify these “weaker” forms of non-Markovianity emerging in these models, by adopting different strategies as shown in [53].

In [53], the authors provide a geometric measure of non-Markovianity that is capable of capturing the amount of non-Markovianity for the CP-divisible models considered above and provide a comparative analysis. Fixing \( x = \lambda^{-1} \) for OUN and \( x = \lambda \) for PLN, it has been shown that the non-Markovianity of PLN is always higher than that of OUN for any finite \( x \) (cf. Fig. 1-(a) of [53]). Note that \( x = 0 \) corresponds to the case \( \lambda \to \infty \) for OUN and \( 1/\lambda \to \infty \) for PLN, which are the Markovian limits of these models. We set \( x = 10 \) and look at the noise-assisted transport phenomenon in a Glauber-Fock oscillator (lattice) under OUN and PLN noise, together with their corresponding Markovian limit. Fig. (4) shows that

**FIG. 4.** Noise-assisted transport phenomenon in a Glauber-Fock oscillator (lattice) as a function of the dephasing rate, \( \gamma \), under (a) Ornstein-Uhlenbeck noise (OUN) and (b) power law noise (PLN). The system was prepared initially in ground state \( |0\rangle \), i.e., \( m = 0 \), \( g = 1 \), \( \omega = 0.5 \) and \( k = 1 \). For (a) \((\text{b})\) \( \lambda \to \infty \) \((\lambda^{-1} \to \infty)\).
for this value, \( x = 10 \), which corresponds to \( \lambda = 0.1 \) for OUN and \( \lambda = 10 \) for PLN, the noise-assisted transport phenomenon shows a higher enhancement over a broader range of dephasing in the case of PLN as compared to OUN, which also presents a higher non-Markovianity.

In Fig. 4(a), we show that the pure numerical calculation of the master equation (11) coincides (as expected) with the solution of Eq. (16), but the latter is significantly more straightforward to solve than the former. Interestingly, even when we do not consider correlations between sites, one can still observe the enhancement in noise-assisted transport in the non-Markovian case described by the master equation (15). This suggests that for the specific model of GF oscillator (lattice) considered in this work, non-Markovianity seems quite advantageous in the noise-assisted transport phenomenon. Increased non-Markovianity in the open system dynamics, allows us to achieve finite \( \langle \hat{n}(t) \rangle \), or equivalently \( \langle \hat{n}(z) \rangle_{\text{class}} \), for larger values of the dephasing rate. Although our findings are limited to the models considered in this work, they are in accordance with recent results in the literature that show positive correlation between non-Markovianity and noise-assisted transport efficiencies [26, 56, 57].

VI. CONCLUSIONS

We have explored the conditions under which the master equation describing a driven quantum harmonic oscillator, interacting with an environment in a non-dissipative way, is equivalent to the master equation describing light propagation in a dynamically disordered photonic lattice – the Glauber-Fock photonic lattice. One of these conditions is that the noise between different sites (waveguides) must be correlated. The second condition is to choose a number of waveguides such that the light do not reach the boundary where the sites corresponding to high number states lie. Further, we have shown that the noise-assisted energy transport phenomenon can be observed in this type of systems and that it is possible to obtain analytical solutions for certain observables quantities, e.g. the average photon number. Using these solutions we can readily predict the maximum amount of energy transferred between all the sites. This, in the Markovian scenario, occurs for decoherence rates comparable to the energy scale of the system. For the non-Markovian case, we found that the range of the dephasing rate, in which the noise-assisted transport occurs, is substantially larger. Our results are in good agreement with recent theoretical [56, 57] and experimental [26] works showing that non-Markovian environments have a strong influence on the energy transport. Looking forward, and following the ideas of Refs. [35, 58], it would be interesting to go beyond the single excitation regime and derive the corresponding master equation of, for example, two correlated particles propagating over these stochastic networks affected by non-Markovian noise.

Appendix A

The time derivative of the density matrix \( \sigma_{nm}(t) \equiv \langle \psi_n \psi_m^* \rangle \) is given as

\[
\frac{d}{dt} \sigma_{nm} = \left( \psi_m^* \frac{d\psi_n}{dt} + \psi_n \frac{d\psi_m^*}{dt} \right),
\]

where each term can be calculated using the stochastic Schrödinger equation:

\[
\psi_m^* \frac{d\psi_n}{dt} = -i \omega \psi_n^* \psi_m^* - i \phi_n(t) \psi_n^* \psi_m^* - i \sum_{j \neq n} \kappa_{nj} \psi_j^* \psi_m^*, \quad (A2a)
\]

\[
\psi_n \frac{d\psi_m^*}{dt} = +i \omega \psi_n^* \psi_m^* + i \phi_m(t) \psi_n^* \psi_m^* + i \sum_{j \neq m} \kappa_{jm} \psi_n \psi_j^*. \quad (A2b)
\]

Performing the stochastic averaging procedure these terms yield

\[
\frac{d}{dt} \sigma_{nm} = -i(n \omega - m \omega) \sigma_{nm} - i \sum_{j \neq n} \kappa_{nj} \sigma_{jm} + i \sum_{j \neq m} \kappa_{jm} \sigma_{nj} - i n \langle \psi_n \psi_m^* \phi_n(t) \rangle + i m \langle \psi_n^* \phi_m(t) \rangle.
\]

In particular, the stochastic averages in the last two terms of the above equation, one needs to resort to the
Novikov’s theorem [48]:

\[
\langle \psi_n \psi^*_m \phi_n(t) \rangle = \sum_p \int dt' \langle \phi_n(t) \phi_p(t') \rangle \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_p(t')} \right\rangle,
\]

(A4a)

\[
= \sum_p \int dt' \Gamma_{np} \delta(t - t') \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_p(t')} \right\rangle,
\]

(A4b)

\[
= \frac{1}{2} \sum_p \Gamma_{np} \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_p(t')} \right\rangle,
\]

(A4c)

\[
= \frac{1}{2} \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_n(t)} \right\rangle,
\]

(A4d)

where the operator \( \delta/\delta \phi_n(t) \) stands for the functional derivative with respect to the stochastic process. Similarly, the second term can be found as

\[
\langle \psi_n \psi^*_m \phi_n(t) \rangle = \frac{1}{2} \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_n(t)} \right\rangle.
\]

(A5)

To obtain Eq. (A4c) and Eq. (A5) we have used the fact that, in the Stratonovich interpretation, \( \int \delta(t) = 1/2 \) [59]. It is important to mention that the Novikov’s theorem is only valid for stochastic Gaussian processes, that can be both Markovian or non-Markovian as well [60]. To compute the corresponding functional derivatives we need the formal integration of Eq. (A3) which, before the stochastic average, is

\[
\psi_n(t) \psi^*_m(t) = \int_0^t dt' \left\{ f(\psi_n \psi^*_m, \ldots) - i n \psi_n \psi^*_m \phi_n(t') + i m \psi_n \psi^*_m \phi_n(t') \right\},
\]

(A6)

where \( f(\psi_n \psi^*_m, \ldots) \) represents all the terms that do not contain stochastic variable, \( \phi_n(t) \). Thus, the functional derivatives are

\[
\frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_n(t)} = -i n \psi_n \psi^*_m + i m \psi_n \psi^*_m \delta_{nm},
\]

(A7a)

\[
\frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \phi_m(t)} = -i n \psi_n \psi^*_m \delta_{nm} + i m \psi_n \psi^*_m,
\]

(A7b)

in which we have used the identity \( \delta \phi_p(t')/\delta \phi_q(t) = \delta_{pq} \delta(t' - t) \) [48]. Using these results we can compute the stochastic average for the last two terms in Eq. (A3) as

\[
-\int \langle \psi_n \psi^*_m \phi_n(t) \rangle = -\frac{1}{2} \Gamma n^2 \rho_{nm} + \frac{1}{2} \Gamma n m \rho_{nm} \delta_{nm},
\]

(A8a)

\[
-\int \langle \psi_n \psi^*_m \phi_m(t) \rangle = \frac{1}{2} \Gamma n m \rho_{nm} \delta_{nm} - \frac{1}{2} \Gamma m^2 \rho_{nm},
\]

(A8b)

and as a result we obtain Eq. (8) of the main text.

**Appendix B**

Applying the Novikov’s theorem [48] in \( \langle \psi_n \psi^*_m \Omega_n(t) \rangle \) we get:

\[
\langle \psi_n \psi^*_m \Omega_n(t) \rangle = \sum_p \int dt' \langle \Omega_n(t) \Omega_p(t') \rangle \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \Omega_p(t')} \right\rangle,
\]

(B1a)

\[
= \sum_p \int dt' \frac{\Gamma_{np}}{2} \delta(t - t') \left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \Omega_p(t')} \right\rangle.
\]

(B1b)

The final aim of this appendix is to know if the master equation of Eq. (13) of the main text, after applying Novikov’s theorem in Eq. (B1b), will be similar to the master equation of Eq. (11). Using the formal integration of Eq. (13), before doing the stochastic average, we can compute the functional derivative of Eq. (B1b) as follows

\[
\frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \Omega_p(t')} \bigg|_{t' = t} = \frac{1}{2} \sum_p \Gamma_{np} \delta(t - t') \left\langle \delta [\psi_n(t) \psi^*_m(t)] \right\rangle,
\]

(B2)

Performing the stochastic average in Eq. (B2) we obtain

\[
\left\langle \frac{\delta [\psi_n(t) \psi^*_m(t)]}{\delta \Omega_p(t')} \right\rangle = -\frac{i}{2} n \delta_{np} \sigma_{nm}(t') + \frac{i}{2} m \delta_{mp} \sigma_{nm}(t').
\]

(B3)
Now we substitute Eq. (B3) in Eq. (B1b):

\[
\langle \psi_n | \psi_m^* \Omega_n(t) \rangle = \sum_p \int dt' \frac{\Gamma\lambda}{2} \delta_{np} e^{-\lambda|t-t'|} \{ -\frac{i}{2} n\delta_{np} \sigma_{nm}(t') + \frac{i}{2} m\delta_{mp} \sigma_{nm}(t') \},
\]

\[
= -\frac{i}{2} n \int dt' \frac{\Gamma\lambda}{2} e^{-\lambda|t-t'|} \sigma_{nm}(t') + \frac{i}{2} m\delta_{mn} \int dt' \frac{\Gamma\lambda}{2} e^{-\lambda|t-t'|} \sigma_{nm}(t'),
\]

\[
\approx -\frac{i}{2} n\sigma_{nm}(t) \int dt' \frac{\Gamma\lambda}{2} e^{-\lambda|t-t'|} + \frac{i}{2} m\delta_{mn} \sigma_{nm}(t) \int dt' \frac{\Gamma\lambda}{2} e^{-\lambda|t-t'|},
\]

where we have made an approximation \( \sigma_{nm}(t') \approx \sigma_{nm}(t) \), i.e., we assume that the dynamics of the density matrix is slower compared with the dynamics of the stochastic processes. Under this approximation we can perform the integral of the above equation,

\[
\int_0^t dt' \frac{\Gamma\lambda}{2} e^{-\lambda|t-t'|} = \frac{\Gamma}{2} (1 - e^{-\lambda t}) \equiv \Gamma(t).
\]

With this result, Eq. (B4c) reduces to Eq. (14) of the main text.
