A note on the fibres of Mori fibre spaces

Giulio Codogni · Andrea Fanelli · Roberto Svaldi · Luca Tasin

Abstract We consider the problem of determining which Fano manifolds can be realised as fibres of a Mori fibre space. In particular, we study the case of toric varieties, Fano manifolds with high index and some Fano manifolds with high Picard rank.

Keywords Fano varieties · Mori fibre spaces · Toric varieties · Vertex-transitive polytopes · High index · High Picard rank

1 Introduction

In algebraic geometry, one of the main goals is to classify algebraic varieties. Rather than distinguishing varieties based on their isomorphism type, one can look at their birational type, i.e. the structure of a non-empty Zariski open set of the variety, which allows more flexibility in the choice of preferred model for the object under scrutiny.

From this point of view, the study of the canonical bundle of a smooth projective variety, that is, the determinant of the cotangent bundle, plays a central role in the classification. There is a stark dichotomy between algebraic varieties that admit sections of powers of the canonical bundle and those that do not.

In fact, while it is expected that the former are birational to a fibration in Calabi–Yau varieties over a base of (log-)general type, using a suitable realization of the Iitaka fibration, the latter are instead expected to be birational to a fibration in Fano varieties over a smaller dimensional base.

The following definition gives the precise notion needed in the latter case. Let us remind the reader that a normal projective variety is said to be Fano if the anticanonical divisor is ample (and in particular it is $\mathbb{Q}$-Cartier).

Definition 1.1 Let $f : X \to Y$ be a dominant projective morphism of normal varieties. Then $X$ is a Mori fibre space (or MFS) if

- $f_*\mathcal{O}_X = \mathcal{O}_Y$ and $\dim Y < \dim X$;
- $X$ is $\mathbb{Q}$-factorial with klt singularities;
- the general fibre is a Fano variety and $\rho(X/Y) := \rho(X) - \rho(Y) = 1$.

While it is a difficult problem to prove that a variety having no non-zero pluricanonical forms is birational to a Mori fibre space, in [5] the authors show, among other things, that this is actually the case if instead the variety is assumed to have a non-pseudoeffective canonical bundle—the two conditions being expected to be equivalent as predicted by the existence of minimal models and the celebrated Abundance Conjecture, cf. [24, Conjecture 3.12]. In view of these considerations, it is natural to wonder about the following matter.

Question 1.2 What type of Fano varieties appear as fibres in a Mori fibre space?

Part of the difficulty in answering the above question lies in the lack of clarity as to what fibres of an MFS one should actually consider. To this end, the notion of fibre-like Fano variety was introduced in [13]. For the sake of simplicity, we only consider the case of smooth fibres.

Definition 1.3 A Fano manifold $F$ is fibre-like if it can be realised as a fibre of a Mori fibre space $f : X \to Y$ over the smooth locus of $f$.

Any Fano manifold with Picard number $\rho = 1$ is fibre-like, via the constant map to a point. When $\rho \geq 2$ the problem of determining whether a variety is fibre-like or not is highly non-trivial. Mori showed in [25, Theorem 3.5] which Fano surfaces are fibre-like. In [13], we systematically study fibre-like Fano varieties by analysing the
action of the monodromy of the MFS on the Néron–Severi group of a general fibre. Moreover, we fully characterize those threefolds that are fibre like, cf. [13, Theorem 1.4] and give the following sufficient condition for fibre-likeness in any dimension.

**Theorem 1.4** ([13, Theorem 3.1]) A smooth Fano variety $F$ is fibre-like if

$$\text{NS}(F)^{\text{Aut}(F)}_\mathbb{Q} = \mathbb{Q}K_F.$$  \hspace{1em} (1)

When $F$ is rigid, then property (1) is equivalent to $F$ being fibre-like.

In [13], we also establish that the fibre-likeness of a Fano manifold $F$ implies an analogous necessary condition: namely, $F$ fibre-like implies

$$\text{NS}(F)^{\text{Mon}(F)}_\mathbb{Q} = \mathbb{Q}K_F,$$

where $\text{Mon}(F)$ is the maximal subgroup of $\text{GL}(\text{NS}(F), \mathbb{Z})$ which preserves the birational data of $F$.

Below we recall some of the consequences of our analysis. First, we construct a large class of examples of fibre-like Fano manifolds.

**Corollary 1.5** ([13, Corollary 4.6]) Let $r, k, d$ be integers with $n \geq 2$ and $kd < n + 1$. Then any smooth complete intersection of $k$ divisors of degree $(d, \ldots, d)$ in $(\mathbb{P}^n)^r$ is fibre-like.

Moreover, since the notion of fibre-likeness is strictly intertwined with the monodromy action, we show that it forces a high degree of symmetry on facets of the nef cone of the variety. Recall that a facet of a polyhedral cone is just a maximal dimensional face. As Fano varieties are Mori dream spaces, any facet $\mathcal{G}$ of the nef cone $F$ corresponds to a contraction $\pi : F \to G$ such that $\mathcal{G} = \pi^*\text{Nef}(G)$.

**Corollary 1.6** ([13, Corollary 3.9]) Let $F$ be a smooth fibre-like Fano variety. Let $\mathcal{G}$ be a facet of the nef cone of $F$ corresponding to a contraction $F \to G$. Then for any other facet $\mathcal{H}$ with contraction $F \to H$ we have that $G$ and $H$ are deformation equivalent.

Let us point out that the definition of fibre-like can be extended to singular varieties (cf. [13, Definition 2.14]) and all results illustrated so far still hold in that setting.

In this note we show that various natural and interesting classes of Fano manifolds are fibre-like.

We first focus on smooth toric Fano varieties. If $F(\Delta)$ is a smooth toric Fano variety with associated polytope $\Delta$, then $F$ is said to be vertex-transitive if the automorphism group of the polytope acts transitively on the set of vertices of $\Delta$. A vertex-transitive toric Fano manifold is fibre-like (see Lemma 2.2) and all the known examples of toric fibre-like Fano varieties seem to be of this kind (cf. Question 5.1).

Among these, projective spaces and $t$-del Pezzo manifolds (see Definition 2.3) are classical examples of vertex-transitive varieties. A generalisation of $t$-del Pezzo manifolds has been introduced in [21] and studied in [33]. We call those Klyachko varieties (see Definition 2.17). We show that Klyachko varieties are vertex-transitive...
and we show that they constitute a fundamental building block in the theory of fibre-like toric Fano manifolds.

**Theorem 1.7** (Propositions 2.13 and 2.23) Let $F = F(\Delta)$ be a $d$-dimensional vertex-transitive Fano manifold.

(i) If there are two vertices of $\Delta$ that are not in the same face (i.e. $\Delta$ is not 2-neighbourly), then $F$ is a power of $\mathbb{P}^1$ or a power of $t$-del Pezzo manifolds.

(ii) If $d \leq 7$, then $F$ is a power of projective spaces or Klyachko varieties.

Next we look at Fano manifolds with high index. As mentioned above, fibre-likeness is completely understood for surfaces and threefolds. Hence, here we focus on Fano varieties of dimension at least 4.

For a Fano manifold $F$, the index $i_F$ is defined as the largest integer that divides $-K_F$ in $\text{Pic}(F)$. The index is one of the most basic numerical invariants for Fano varieties: there is a complete classification of Fano manifolds with Picard number at least 2 and index $i \geq n - 2$ due to Kobayashi–Ochai [22], Fujita [16, 17] and Mukai [26]. Moreover, Wiśniewski [34] classified Fano manifolds with index $i \geq (n + 1)/2$. Notice that the only case for which $i < (n + 1)/2$ and $i \geq n - 2$ is $i = 2$ and $n = 4$.

When the Fano index is greater than the above bounds, we show that fibre-like Fano varieties can be explicitly classified.

**Theorem 1.8** (Propositions 3.2 and 3.3) Let $F$ be a fibre-like Fano manifold with Picard number $\rho \geq 2$ and dimension $n \geq 4$.

- If $i_F \geq (n + 1)/2$, then $F \cong \mathbb{P}^{n/2} \times \mathbb{P}^{n/2}$ ($n$ even) or $F \cong \mathbb{P}(T_{\mathbb{P}(n + 1)/2})$ ($n$ odd).
- If $n = 4$ and $i_F = 2$ (i.e. $F$ is a Mukai fourfold), then $F$ is isomorphic to one of the following:
  (i) a double cover of $\mathbb{P}^2 \times \mathbb{P}^2$ branched along a degree-$(2, 2)$ divisor;
  (ii) an intersection of two degree-$(1, 1)$ divisors in $\mathbb{P}^3 \times \mathbb{P}^3$;
  (iii) $\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1$.

Finally, we discuss families of Fano manifolds with high Picard number.

As there only exist finitely many families of Fano manifolds in any given dimension, there must be an upper bound on the Picard number in fixed dimension. It is a natural question to ask whether it is possible to compute such bound.

The only known examples of Fano manifolds—other than products—of dimension $n \geq 4$ and Picard number at least $n + 5$ are birational modifications of the blow-up of $\mathbb{P}^4$ at eight points in general position. These manifolds have been studied in [10]; among other results, the authors showed that they are fibre-like. Here, we study the only known examples of Fano manifolds—again, other than products—that have dimension $n \geq 4$ and Picard number at least $n + 4$. These are birational modification of $\mathbb{P}^n$ blown up at $n + 3$ general points, with $n$ even. They are isomorphic to the space of $(m - 1)$-planes in the intersection of two quadrics in $\mathbb{P}^{n+2}$, where $n = 2m$. Building on [1], we can prove the following result.

**Theorem 1.9** (Theorem 4.2) Let $n \geq 4$ be an even integer. An $n$-dimensional Fano manifold birational to the blow-up of $\mathbb{P}^n$ at $n + 3$ general points is fibre-like.

The structure of the paper is as follows. Section 2 is dedicated to toric Fano manifolds. In Sect. 3 we discuss the fibre-likeness of Fano manifolds with high index. Section 4
A note on the fibres of Mori fibre spaces

is devoted to the study of certain families of Fano manifolds with high Picard number. Finally, in Sect. 5 we present new questions and research directions.

**Notation**

The term *variety* stays for separated, integral and proper scheme of finite type over \( \mathbb{C} \). A *manifold* is a smooth variety. For the definitions of singularities in the context of the minimal model program, see [23, Section 2].

**2 Toric Fano varieties**

The first class of examples we want to discuss is given by toric varieties. We will recall here only some notions and refer to [14] for an exhaustive treatment of the topic. Toric varieties can be described in terms of combinatorial data and this makes them particularly suitable to test general conjectures on Fano varieties.

Let \( N \) be a free abelian group of rank \( n \) and set \( N_\mathbb{Q} := N \otimes \mathbb{Z} \mathbb{Q} \). Let \( \Sigma \subset N_\mathbb{Q} \) be a fan of a \( d \)-dimensional toric Fano variety \( F \) and let \( \Delta \) be the polytope associated to the anti-canonical polarisation. Furthermore, \( M \) will denote the dual of \( N \).

The vertices of \( \Delta \), denoted by \( V(\Delta) \), are the generators of \( \Sigma \). We denote by \( O(\sigma) \) the closure of the orbit corresponding to \( \sigma \in \Sigma \), which is an irreducible invariant subvariety.

Let \( A_1 \) be the group of 1-cycles on \( F \) modulo numerical equivalence and set \( N_1 = A_1 \otimes \mathbb{Q} \). Inside \( N_1 \), we consider the Kleiman–Mori cone \( \overline{NE}(F) \) generated by the effective 1-cycles. We have the following standard exact sequence (cf. [14, Chapter 4, Theorem 1.3])

\[
0 \to A_1(F) \to \mathbb{Z}^{V(\Delta)} \to N \to 0, \tag{2}
\]

which by duality yields the following one:

\[
0 \to M \to \mathbb{Z}^{V(\Delta)} \to \text{NS}(F) \to 0. \tag{3}
\]

**2.1 Vertex-transitive polytopes**

The following definition of vertex-transitivity for polytopes is classical, although some authors refer to them as isogonal polytopes (cf. [19, 19.5, Enumeration]).

**Definition 2.1** A polytope \( \Delta \) is vertex-transitive if \( \text{Aut}(\Delta) \) acts transitively on the vertices of \( \Delta \). If \( \Delta \) is associated to a toric Fano variety \( F \), then \( F \) is vertex-transitive.

This class of varieties is interesting from our prospective for the following reason.

**Lemma 2.2** Vertex-transitive Fano manifolds are fibre-like.

**Proof** Let \( F(\Delta) \) be a Fano toric variety and let \( G = \text{Aut}(\Delta) \). As explained in the proof of [13, Theorem 5.7], the exact sequence in (3) yields the following sequence:

\[
0 \to M_\mathbb{Q}^G \to (\mathbb{Q}^{V(\Delta)})^G \to \text{NS}(F)^G_\mathbb{Q} \to 0.
\]
Then, $F$ is fibre-like if and only if $t - k = 1$, where $t$ is the number of orbits of the action of $G$ on $V(\Delta)$ and $k = \dim M_{\mathbb{Q}}^G$.

If $F$ is vertex-transitive, then $t = 1$ and so [13, Lemma 5.10] implies that $k = 0$, which means that $F$ is fibre-like.

Denote by $d$ the dimension of the toric Fano variety $F$ and by $m$ the number of vertices of $\Delta$.

The first non-trivial class of vertex-transitive Fano varieties are $t$-del Pezzo manifolds.

**Definition 2.3** The $d$-dimensional $t$-del Pezzo manifold $V_d$ (with $d$ even) is the smooth toric Fano variety whose associated polytope has vertices

$$V(\Delta) = \{ e_1, \ldots, e_d, -e_1, \ldots, -e_d, (e_1 + \cdots + e_d), -(e_1 + \cdots + e_d) \},$$

where $e_1, \ldots, e_d$ is the standard basis of $\mathbb{Z}^d$.

**Remark 2.4** In the literature on toric geometry, these manifolds are simply named del Pezzo varieties. We added the prefix “$t$-” in order to distinguish them from the del Pezzo manifolds appearing in Sect. 3.

$T$-del Pezzo polytopes are symmetric with respect to the origin, i.e., $-\Delta = \Delta$. Polytopes satisfying this condition are also said to be centrally symmetric, cf. [33]. A classical result by Voskresenki and Klyachko shows that del Pezzo varieties are essentially the only centrally symmetric toric varieties.

**Theorem 2.5** ([33, Theorem 6]) Let $F$ be a toric Fano manifold such that $\Delta$ is centrally symmetric. Then $F$ is isomorphic to a product of projective lines and $t$-del Pezzo varieties.

Coming back to vertex-transitive varieties, we can prove the following structural result.

**Lemma 2.6** Let $F = F(\Delta)$ be a toric Fano manifold which is vertex-transitive. Then there exists a unique vertex-transitive Fano toric manifold $F_{\text{min}}$ and a positive integer $n$ such that $F \cong (F_{\text{min}})^n$.

**Proof** Let $\Delta = \Delta_1^{n_1} \times \cdots \times \Delta_r^{n_r}$ be a prime decomposition of $\Delta$. The automorphism group of $\Delta$ is given by (see for example [18, Theorem A])

$$\text{Aut}(\Delta) = \prod_{i=1}^r (\text{Aut}(\Delta_i) \rtimes S_{n_i}),$$

with its natural action on $\Delta$.

Since $\text{Aut}(\Delta)$ acts transitively on the vertices of $\Delta$, the lemma follows immediately.  \(\square\)
2.2 Primitive collections

Primitive collections are an essential tool to study the birational geometry of Fano toric varieties. We refer to [31] and [8] for further details.

**Definition 2.7** Let $F = F(\Delta)$ be a toric Fano variety. A subset $P \subset V(\Delta)$ is called a primitive collection if the cone generated by $P$ is not in $\Sigma$, but for any $x \in P$ the elements of $P \setminus \{x\}$ generate a cone in $\Sigma$.

For a primitive collection $P = \{x_1, \ldots, x_k\}$ denote by $\sigma(P)$ the (unique) minimal cone in $\Sigma$ such that $(x_1 + \cdots + x_k) \in \sigma(P)$. Let $y_1, \ldots, y_h$ be generators of $\sigma(P)$, then

$$r(P) : x_1 + \cdots + x_k = b_1 y_1 + \cdots + b_h y_h$$

(4)

where $b_i$ is a positive integer for all $1 \leq i \leq h$: we have simply written the element $x_1 + \cdots + x_k$ in terms of the generators $y_1, \ldots, y_h$ (the coefficients are positive since $(x_1 + \cdots + x_k)$ is in the cone $\sigma(P)$).

The linear relation (4) is called the primitive relation of $P$ and the cone $\sigma(P)$ is called the focus of $P$. The integer $k$ is called the length of $r(P)$ and the degree of $P$ is defined as $\text{deg } P = k - \sum b_i$.

Here it is convenient to write down explicitly the group of 1-cycles $A_1$ of $F$ as:

$$A_1(F) \cong \left\{ (b_x)_{x \in V(\Delta)} \in \text{Hom}(\mathbb{Z}^m, \mathbb{Z}) : \sum_{x \in V(\Delta)} b_x x = 0 \right\}.$$ 

The previous isomorphism is clear looking at the exact sequence (2). So it is natural to identify primitive relations with the associated cycles. Moreover, we work on Fano varieties, so $\text{deg } P = -(K_F \cdot r(P)) > 0$ for all primitive relations.

Consider now a primitive collection $P$ on $F$ for which the relation $r(P)$ is extremal, meaning that it generates an extremal ray in $\overline{\text{NE}}(F)$. One sees that the exceptional locus of the associated contraction is given by $O(\sigma(P))$ and moreover, according to the dimension of $\sigma(P)$, one recovers:

- divisorial contraction when $\sigma(P)$ is a 1-dimensional cone and the contracted divisor is precisely the one associated to the ray;
- Mori fibration, when $\sigma(P)$ coincides with the origin;
- flipping contraction otherwise.

Let us recall some useful results.

**Proposition 2.8** ([8, Proposition 4.3]) Let $\gamma \in \overline{\text{NE}}(F) \cap A_1(F)$ be a 1-cycle of $F$ for which $(K_F \cdot \gamma) = -1$. Then $\gamma$ is extremal.

**Theorem 2.9** ([31, Theorem 2.4], [8, Theorem 1.5]) Let $R \subset \overline{\text{NE}}(F)$ be an extremal ray and let $\gamma \in R \cap A_1(F)$ be a primitive cycle. Then there exists a primitive collection $P = \{x_1, \ldots, x_k\}$ such that

$$\gamma = r(P) : x_1 + \cdots + x_k = b_1 y_1 + \cdots + b_h y_h.$$ 

Moreover, for any cone $\nu = \langle z_1, \ldots, z_t \rangle$ which verifies

\[ Springer \]
\begin{itemize}
  \item \( \{z_1, \ldots, z_t\} \cap \{x_1, \ldots, x_k, y_1, \ldots, y_h\} = \emptyset; \) and
  \item \( \langle y_1, \ldots, y_h \rangle + v \in \Sigma; \)
\end{itemize}

the following holds for all \( i = 1, \ldots, h: \)
\[ \langle x_1, \ldots, x_i, \ldots, x_k, y_1, \ldots, y_h \rangle + v \in \Sigma. \]

\textbf{Proposition 2.10} ([8, Proposition 3.4]) Let \( P \) a primitive extremal collection for \( F \) and write
\[ \sigma(P) = \langle y_1, \ldots, y_h \rangle. \] Then for any other primitive collection \( Q \neq P \) for which \( P \cap Q \neq \emptyset, \) the set \( (Q \setminus P) \cup \{y_1, \ldots, y_h\} \) contains a primitive collection.

The following observation is easy but useful for our analysis.

\textbf{Remark 2.11} Consider a relation
\[ a_1 x_1 + \cdots + a_k x_k = b_1 y_1 + \cdots + b_h y_h \]
among the vertices of \( \Delta, \) with \( a_i, b_j > 0 \) for all \( i, j. \) If \( \sum a_i \geq \sum b_j, \) then [8, Lemma 1.4] implies that \( \langle x_1, \ldots, x_k \rangle \notin \Sigma. \)

We recall now the following definition.

\textbf{Definition 2.12} \((k\text{-neighbourly polytope})\) A polytope is \( k\text{-neighbourly} \) if every set of \( k \) vertices lies on one of its face. A Fano variety \( F(\Delta) \) is \( k\text{-neighbourly} \) if the corresponding polytope \( \Delta \) is.

We want now to understand the structure of vertex-transitive polytopes: the following result is the first step towards a classification of vertex-transitive those.

\textbf{Proposition 2.13} Let \( F = F(\Delta) \) be a vertex-transitive toric Fano manifold. Then

\begin{enumerate}[(i)]
  \item \( F = (\mathbb{P}^1)^d \) or \( F = (V_k)^r \) for some \( r \) and \( k, \) or
  \item \( \Delta \) is \( 2\text{-neighbourly}. \)
\end{enumerate}

\textbf{Proof} Let us assume that \( \Delta \) is not \( 2\text{-neighbourly}, \) which implies the existence of a primitive collection with two elements. We claim that this primitive relation can be assumed to be of the form
\[ x + y = 0. \tag{5} \]

To show this, we assume such a relation does not exist and seek for contradiction. Take a primitive collection \( P_1 = \{x_1, x_2\} \) verifying the relation \( R_1: x_1 + x_2 = y_1. \) Let \( \text{Aut}(\Delta) \) act on \( P_1 \) to obtain a family of primitive collections \( \mathcal{P} = \{P_i\}_{1 \leq i \leq r} \) with relations \( \mathcal{R} = \{R_i\}_{1 \leq i \leq r} \). Since the action is transitive by hypothesis, any vertex of \( \Delta \) appears the same number of times as right-hand side of these relations and so the number of vertices \( m := \# \{V(\Delta)\} \) divides \( r. \) This implies that the \( P_i \)'s cannot be all disjoint, otherwise \( 2r = m. \) Hence, we may assume that \( P_2 = \{x_1, x_3\}, x_2 \neq x_3, \) with relation \( R_2: x_1 + x_3 = y_2. \)

The two relations \( R_1 \) and \( R_2 \) give \( x_2 + y_2 = x_3 + y_1, \) which implies, by Remark 2.11, that \( \{x_2, y_2\} \) is also a primitive collection. The two relations
\[ R': x_3 + y_1 = z_1 \quad \text{and} \quad R'': x_2 + y_2 = z_1 \]
are extremal, so Proposition 2.8 and Theorem 2.9 imply that \( \langle y_1, y_2 \rangle \in \Sigma \).

This is a contradiction, since \( y_1 + y_2 = x_1 + z_1 \). We proved the existence of (5).

Now act with Aut(\( \Delta \)) to get exactly \( m/2 \) relations of the same form. One can verify that those are disjoint. Using the vertex-transitivity of \( \Delta \), we deduce that for any vertex \( \overline{x} \) there is a vertex \( \overline{y} \) for which \( \overline{x} + \overline{y} = 0 \), i.e. \( \Delta \) is centrally symmetric. Theorem 2.5 concludes the proof. \( \square \)

We study now the extremal contractions of 2-neighbourly vertex-transitive toric Fano manifolds.

**Lemma 2.14** Let \( F = F(\Delta) \) be a vertex-transitive, 2-neighbourly toric Fano manifold. Then there exist an integer \( k \geq 3 \) and a set of primitive collections \( \mathcal{P} = \{ P_i \}_{i=1}^r \) such that \( r = m/k \), \( |P_i| = k \), \( \sigma(P_i) = 0 \) and \( P_i \cap P_j = \emptyset \) for any \( i \neq j \). Moreover, these are the only primitive relations with focus equal to zero.

**Proof** The result in [2, Proposition 3.2] implies that there exists a primitive collection \( P_1 \) with \( \sigma(P_1) = 0 \). Define \( k := |P_1| \). Since \( \Delta \) is 2-neighbourly, we have \( k \geq 3 \).

Act with Aut(\( \Delta \)) to get a set of primitive collections \( \mathcal{P} = \{ P_i \}_{1 \leq i \leq r} \) verifying \( \sigma(P_i) = 0 \) and for which \( \bigcup_{i=1}^r P_i = V(\Delta) \). Let us prove they are disjoint, assuming that \( P_i \cap P_j \neq \emptyset \) for some \( i, j \) and seeking for contradiction. Write \( P_i = \{ x_1, \ldots, x_k \} \) and \( P_j = \{ x_1, \ldots, x_h, y_{h+1}, \ldots, y_k \} \) with \( y_s \neq x_t \) for any \( s, t \). Then

\[
x_{h+1} + \cdots + x_k = y_{h+1} + \cdots + y_k.
\]

Remark 2.11 gives the required contradiction, since \( x_{h+1}, \ldots, x_k \) generate a cone in \( \Sigma \). Moreover, one sees that there are no other primitive relations with focus equal to zero. \( \square \)

**Proposition 2.15** In the notation of Lemma 2.14, assume that one of the relations \( P_i \) is extremal. Then \( F(\Delta) = (\mathbb{P}^{k-1})^r \). On the other hand, if any of these relations is not extremal then \( F \) does not admit any extremal contraction of fibre type.

**Proof** Up to reordering, assume that \( P_1 \) is extremal. Acting with Aut(\( \Delta \)), we deduce that all \( P_i \)'s are extremal. We claim these are the only primitive collections. In fact, let \( \widehat{P} \) be a primitive collection such that \( \widehat{P} \notin \mathcal{P} \) and \( \widehat{P} \) has minimal cardinality among the primitive collections which are not in \( \mathcal{P} \). We may assume that \( P_1 \cap \widehat{P} \neq \emptyset \). Using Proposition 2.10, we deduce that the set \( \widehat{P} \setminus P_1 \) contains a primitive collection. Contradiction, since \( |\widehat{P}| \) is minimal.

Note that \( k \) is the index of \( K_F \), \( \dim F = d = (k - 1)r \) and \( \rho(F) = r \) by [2, Corollary 4.4]. So apply [9, Theorem 1] (Mukai’s Conjecture) to obtain the first part of the statement.

For the last part, just observe that an extremal contraction of fibre type would provide a primitive collection \( P \) with trivial focus \( \sigma(P) = 0 \). \( \square \)
Lemma 2.16 Let $F = F(\Delta)$ be a vertex-transitive, 2-neighbourly toric Fano manifold. Then there are no extremal relations of the form

$$x_1 + \cdots + x_k = by_1.$$  \hfill (6)

In particular, $F$ does not admit any extremal divisorial contraction.

Proof Let us assume that an extremal relation of the form (6) exists and seek for contradiction. Let $\mathcal{R} = \{R_i\}_{1 \leq i \leq r}$ be the set of extremal relations obtained acting with $\text{Aut}(\Delta)$ and denote with $P_i$ the associated collections. Assume that $x_1$ appears only in one $P_i$. Since by transitivity any vertex appears the same number of times, we get that the $P_i$‘s are disjoint. In particular $m = kr$, where $m = \# \{V(\Delta)\}$. On the other hand, we have that $m$ divides $r$, because any vertex appears the same number of times as right-hand side. This implies $k = 1$, which is a contradiction.

Hence there is an extremal primitive relation different from (6) of the form

$$x_1 + z_2 + \cdots + z_k = by_2.$$ 

Assume $y_2 \notin \{x_2, \ldots, x_k, y_1\}$ (the other case is analogous).

We have $b_1y_2 + x_2 + \cdots + x_k = by_1 + z_2 + \cdots + z_k$, and, since $\Delta$ is 2-neighbourly, we know that $\langle y_1, y_2 \rangle$ is a cone of $\Sigma$. Theorem 2.9 implies that $\langle y_2, x_2, \ldots, x_k \rangle \in \Sigma$, but this contradicts Remark 2.11. \hfill \Box

2.3 Klyachko varieties

Looking for interesting examples of vertex-transitive toric varieties, we found a generalisation of $t$-del Pezzo varieties, which were introduced in [21] and studied in [33].

Let us remark that our notation is not the same as Klyachko’s (cf. Remark 2.18). Fix a basis $e_1, \ldots, e_d$ of a lattice $N \cong \mathbb{Z}^d$, with $d \geq 2$ and let $k$ be a positive integer such that $(k - 1)d$.

Definition 2.17 The Klyachko variety of order $k$ and dimension $d$ is the toric Fano variety $W^k_d$ with polytope $\Delta^k_d \subset N$ having vertices

$$V(\Delta^k_d) = \{ e_1, e_2, \ldots, e_d, e_1 + \cdots + e_d, - (e_1 + \cdots + e_{k-1}), -(e_k + \cdots + e_{2k-2}), \ldots, -(e_{d-k+2} + \cdots + e_d), - (e_1 + e_k + \cdots + e_{d-k+2}), -(e_2 + e_{k+1} + \cdots + e_{d-k+3}), \ldots, - (e_{k-1} + e_{2k-2} + \cdots + e_d) \}.$$ 

Remark 2.18 When $d$ is even, $W^2_d$ is the $t$-del Pezzo manifold $V_d$.

In [33], the varieties $W^k_d$ are introduced as $P_{m,n}$. The dictionary between the indices is:

$$d = (m - 1)(n - 1), \quad k = m \text{ (or } n).$$

As we will see in Lemma 2.19, our definition of $k$ is consistent.
If $W_k^d$ is smooth (cf. Proposition 2.21), we can describe some birational geometry of Klyachko varieties.

The 1-dimensional cones of the fan of $W_k^d$ coincide with the 1-dimensional cones of the fan of the blow-up $Z_k^d$ of $(\mathbb{P}^{k-1})^d/(k-1)$ in $k$ invariant points. This implies that $W_k^d$ and $Z_k^d$ are isomorphic in codimension one and $W_k^d$ is a Fano model of $Z_k^d$ (cf. Sect. 4 for other examples of fibre-like Fano manifolds obtained as small modifications of blow-ups of projective spaces).

**Lemma 2.19** For any integers $d$ and $m$, $W_{md}^{d+1} = W_{md}^{m+1}$.

**Proof** Assume $m \leq d$ and consider the vertices of $W_{md}^{d+1}$:

\[ \{ e_1, e_2, \ldots, emd, e_1 + \cdots + emd, - (e_1 + \cdots + ed), - (e_{d+1} + \cdots + 2d), \ldots, - (e_{m(d-1)+1} + \cdots + emd), - (e_{1} + ed + \cdots + emd), - (e_{2} + 2d + \cdots + emd) \} \]

The following transformation:

\[ e_{mi+j}^' := e_{d(j-1)+i+1} \]

where $i \in \{0, \ldots, d\}$ and $j \in \{1, \ldots, m-1\}$ gives the identification. \( \square \)

We study now symmetries and singularities of Klyachko varieties.

**Lemma 2.20** The Fano varieties $W_k^d$ are vertex-transitive, reflexive and have terminal singularities, for all $d, k$.

**Proof** Let us fix $k$ and observe that Lemma 2.19 provides the following identification: $W_{k-1}^{k-1} \cong W_{k-1}^2$.

Vertex-transitivity is proved by induction on $d$: assume that for any $(k-1)|d'$ and $d' < d$, the variety $W_{d'}^k$ is vertex-transitive. We write the projections

\[ \pi_i : \Delta_d^k \rightarrow \langle e_{i+1}, e_{i+2}, \ldots, e_{i+k-1} \rangle \]

with $i = 0, \ldots, d - k + 1$. By inductive hypothesis, the images via the $\pi_i$'s of $\Delta_d^k$ are vertex-transitive and they are all isomorphic to $\Delta_{d-k+1}^k$. To prove the transitivity for the whole polytope, we act with $GL(N_{\mathbb{Q}})$ to exchange the subspaces $\langle e_{i+1}, e_{i+2}, \ldots, e_{i+k-1} \rangle$. We write now $W = W_k^d$ and $\Delta = \Delta_d^k$ to simplify the notation and prove reflexivity. Look at the dual polytope $\Delta^* \subset M_{\mathbb{Q}}$: we claim that no lattice point lies between the affine hyperplane spanned by the facets of $\Delta^*$ and its parallel through the origin. The claim holds for the hyperplane $\{ x_1 = -1 \} \subset M_{\mathbb{Q}}$, so acting with $\text{Aut}(\Delta)$ on $\Delta^*$ we conclude.

Terminality can be translated on polytopes with the condition

\[ \Delta \cap N = V(\Delta) \cup \{0\}. \]
We assume there exists a non-zero \( v \in \Delta \cap N \) which verifies \( v \notin V(\Delta) \) and seek for contradiction. Without loss of generality, assume that \( v \) is not in the subspace \( H \) generated by \( e_1, \ldots, e_{k-1} \) and let \( \pi_H \) be the projection from \( H \). Then the image \( \Delta_H := \pi_H(\Delta) \) is a Klyachko polytope, \( \pi_H(v) \in \Delta_H \) and \( \pi_H(v) \notin V(\Delta_H) \cup \{0\} \).

Since \( W_d^2 \) is terminal for \( d \geq 2 \), we obtain terminality by induction.

We analyse smoothness, together with \( \mathbb{Q} \)-factoriality, for the Klyachko varieties. It turns out that these properties depend on some divisibility conditions on the indices \( d \) and \( k \) (cf. [33]).

Let us fix some notation. For any positive \( d \) and \( k \) let \( \overline{d}_k \) be the smallest non-negative integer \( r \) which verifies \( d \equiv r \mod k \).

Fix integers \( k \geq 2 \) and \( h \geq 1 \) and let \( \{x_1, \ldots, x_d\} \) be coordinates on \( N_\mathbb{Q} \). Then define the following linear form on \( N_\mathbb{Q} \):

\[
L_{k,h} := \sum_{i=0}^{k-3} \left(x_{h+ik} + x_{h+ik+1} + \cdots + x_{h+ik+k-2} - (k-1)x_{h+ik+(k-1)}\right).
\]

The following proposition already appeared in [33], in a different notation.

**Proposition 2.21** The Klyachko variety \( W_d^k \) is smooth if \( \gcd(d-1, k) = 1 \). If \( \gcd(d-1, k) \neq 1 \), then \( W_d^k \) is not \( \mathbb{Q} \)-factorial.

**Proof** The polytope \( \Delta := \Delta_d^k \) is not simplicial for \( d = (k-1)^2 \), since the hyperplane \( \{L_{k,1} + x_d = 1\} \) supports a facet of \( \Delta \) with \( k(k-1) \) vertices.

On the other hand, we claim that the polytope \( \Delta \) is smooth for \( d = k(k-1) \). To show this, one can see that any facet of \( \Delta \) containing the vertex \( (1, 1, \ldots, 1) \) also contains at least \((k-1)(k-2) + 1\) elements of the standard basis. This implies that the hyperplane

\[
\{a_1x_1 + \cdots + a_dx_d = 1\}
\]

supporting the facet has (exactly as for the hyperplane \( \{L_{k,1} + x_d = 1\} \)):

- \((k-1)(k-2) + 1\) coefficients equal to 1;
- \(k-2\) coefficients equal to \(-(k-1)\);
- \(k-1\) coefficients equal to 0.

One can verify that the vertices of all these facets give a basis of \( N_\mathbb{Q} \). Using the transitivity of \( \text{Aut}(\Delta) \) we obtain the claim.

The general result on smoothness is proved via induction on \( k \) and \( d \). Two cases are easy:

- \( k = 2 \) and any \( d \);
- \( d = 2 \).

Take \( \Delta_d^k \) with \( k, d \geq 3 \): if \( d < (k-1)^2 \) then \( \Delta_d^k \cong \Delta_d^{l+1} \), where \( l := k - \overline{d}_k \) and \( d = l(k-1) \). Since \( \gcd(d-1, k) = \gcd(l+1, k) = \gcd(l+1, d-1) \), we conclude by induction of \( k \).
Assume now \( d > k(k - 1) \). Define \( h := d - k(k - 1) \) and take the plane \( H \)
generated by \( \{ e_{h+1}, e_{h+2}, \ldots, e_d \} \) with projection \( \pi_H \). Let define \( \Delta_H := \pi_H(\Delta^k_d) \);
then \( \Delta_H = \Delta^k_h \) and \( \gcd(d - 1, k) = \gcd(h - 1, k) \). For any facet \( \mathcal{F} \) of \( \Delta^k_h \) supported
on the hyperplane \( \{ P(x_1, \ldots, x_h) = 1 \} \) we get a facet \( \mathcal{F}' \) of \( \Delta^k_d \) supported on \( \{ P + L_{k,(h+1)} + (x_{d-k+1} + \cdots + x_{d-1} - (k - 1) x_d) = 1 \} \).

Observe that \( |V(\mathcal{F}')| = |V(\mathcal{F})| + k(k - 1) \). So if \( \Delta^k_h \) is not simplicial, neither \( \Delta^k_d \)
is so. Analogously, one checks that \( \Delta^k_h \) is smooth if and only if \( \Delta^k_d \) is so. We conclude
via induction on \( d \).

\[ \square \]

**Remark 2.22** As a consequence of the previous proposition, if \( k \) is a prime number
then \( W^k_d \) is smooth, unless \( d \equiv 1 \mod k \).

### 2.4 Low dimension

The results and the methods of the previous subsections are enough to classify all
vertex-transitive Fano manifolds up to dimension 7. The result is confirmed by Table 1,
which collects the Fano toric manifolds up to dimension 8 which are fibre-like.\(^1\)

**Proposition 2.23** Let \( F = F(\Delta) \) be a \( d \)-dimensional vertex-transitive Fano manifold.
If \( d \leq 7 \), then \( F \) is a power of projective spaces or Klyachko manifolds.

**Proof** The result can be proven using the software MAGMA together with the classification
of smooth toric Fano varieties from the Graded Ring Database [7] (cf. Table 1):
giving as input a list of smooth Fano polytopes, MAGMA can check in which cases \( \text{Aut}(\Delta) \)
acts transitively on the vertexes.\(^2\)

When the dimension is at most 4, we are able to provide the following short argument,
which does not require computer computations.

Let us start with \( d = 2 \). If \( \Delta \) is not 2-neighbourly, then Proposition 2.13 implies that
\( F \cong \mathbb{P}^1 \times \mathbb{P}^1 \) or \( F \cong V_2 \). If \( \Delta \) is 2-neighbourly, then there is an extremal collection
\( P = \{ x_1, x_2, x_3 \} \) for which \( \sigma(P) = 0 \) and so, by Proposition 2.15, we have \( F \cong \mathbb{P}^2 \).

Assume now \( d = 3 \). If \( \Delta \) is not 2-neighbourly, then Proposition 2.13 implies that
\( F \cong (\mathbb{P}^1)^3 \). If \( \Delta \) is 2-neighbourly, then the extremal relations could only be of the form \( x_1 + x_2 + x_3 = 0 \) (contradiction by Proposition 2.15), \( x_1 + x_2 + x_3 = y_1 \)
(contradiction by Lemma 2.16) or \( x_1 + x_2 + x_3 + x_4 = 0 \). In this last case, \( F \cong \mathbb{P}^3 \)
by Proposition 2.15.

---

\(^1\) The table appeared in [13] and has been obtained using the software MAGMA together with the Graded
Ring Database [7] (for further details on the classification, cf. [28]).

\(^2\) We briefly describe the MAGMA code. Given an integer \( i \), the function \( \text{PolytopeSmoothFano}(i) \) gives
the polytope of the \( i \)th toric Fano in the Graded Ring Database; we denote by \( N \) the number of Fano
polytopes in the database; at the end of a run of the following code, the variable \( \text{Pol} \) will contain the list of
vertex-transitive toric Fano polytopes in the Graded Ring Database.

\[
\text{Pol} := [**];
\]

for \( i := 1 \) to \( N \) do if \# \{ \text{v in AutomorphismGroup (PolytopeSmoothFano(i))} : \text{v in Vertices(PolytopeSmoothFano(i))} \} \) = \text{Dimension(FixedSubspaceToPolyhedron(AutomorphismGroup(PolytopeSmoothFano(i))))} eq 1 then

\[
\text{Pol} := \text{Append(Pol, PolytopeSmoothFano(i))};
\]
end if; end for;
Assume finally that $d = 4$. If $\Delta$ is not 2-neighbourly, then by Proposition 2.13 we get $X \cong (\mathbb{P}^1)^4$, $X \cong (V_2)^2$ or $X \cong V_4$. If there is an extremal relation of the form $x_1 + x_2 + x_3 = 0$, then by Proposition 2.15 we have $X \cong \mathbb{P}^2 \times \mathbb{P}^2$.

Hence, assume that $\Delta$ is 2-neighbourly and let $P$ be an extremal primitive collection. By Theorem 2.9 we have $|P| + |\sigma(P)| \leq 5$. By Lemma 2.16 we conclude that there is an extremal relation of the form $x_1 + x_2 + x_3 = y_1 + y_2$ or $x_1 + \cdots + x_5 = 0$. In the second case $X \cong \mathbb{P}^4$ and so we can assume to have $x_1 + x_2 + x_3 = y_1 + y_2$. From here it is not difficult to see that one should have $|V(\Delta)| \geq 12$, which is impossible by [9, Theorem 1].

\[\square\]

**Remark 2.24** The 8-dimensional polytope denoted by $\tilde{W}$ in Table 1 is not a Klyachko variety and we do not have a classical description of it.

### 3 Fano manifolds of high index

An important invariant of a Fano manifold $F$ is its index, $i_F$, defined as the largest integer that divides $-K_F$ in $\text{Pic}(F)$. There is a complete classification of Fano manifolds of high index. In particular, we have

| Dimension | # Vertices | Description | ID |
|-----------|------------|-------------|----|
| 2         | 6          | $V_2$       | 2  |
| 2         | 4          | $\mathbb{P}^1 \times \mathbb{P}^1$ | 4  |
| 2         | 3          | $\mathbb{P}^2$ | 5  |
| 3         | 6          | $(\mathbb{P}^1)^3$ | 21 |
| 3         | 4          | $\mathbb{P}^3$ | 23 |
| 4         | 10         | $V_4$       | 63 |
| 4         | 12         | $V_2 \times V_2$ | 100 |
| 4         | 8          | $(\mathbb{P}^1)^4$ | 142 |
| 4         | 6          | $\mathbb{P}^2 \times \mathbb{P}^2$ | 146 |
| 4         | 5          | $\mathbb{P}^4$ | 147 |
| 5         | 10         | $(\mathbb{P}^1)^5$ | 1003 |
| 5         | 6          | $\mathbb{P}^5$ | 1013 |
| 6         | 14         | $V_6$       | 1930 |
| 6         | 12         | $W_6^3$     | 5817 |
| 6         | 18         | $(V_2)^3$   | 7568 |
| 6         | 12         | $(\mathbb{P}^1)^6$ | 8611 |
| 6         | 9          | $(\mathbb{P}^2)^3$ | 8631 |
| 6         | 8          | $(\mathbb{P}^3)^2$ | 8634 |
| 6         | 7          | $\mathbb{P}^6$ | 8635 |
| 7         | 14         | $(\mathbb{P}^1)^7$ | 80835 |
| 7         | 8          | $\mathbb{P}^7$ | 80891 |
| 8         | 18         | $V_8$       | 106303 |
| 8         | 15         | $W_8^3$     | 277415 |
| 8         | 20         | $(V_4)^2$   | 442179 |
| 8         | 24         | $(V_2)^4$   | 790981 |
| 8         | 12         | $\tilde{W}$ | 830429 |
| 8         | 16         | $(\mathbb{P}^1)^8$ | 830635 |
| 8         | 12         | $(\mathbb{P}^2)^4$ | 830767 |
| 8         | 10         | $(\mathbb{P}^4)^2$ | 830782 |
| 8         | 9          | $\mathbb{P}^8$ | 830783 |
ifolds with index $i_F \geq n - 2$ and $i_F \geq (n + 1)/2$. In this section we investigate the fibre-likeness of these varieties, assuming $n \geq 4$ (fibre-like Fano threefolds have been classified in [13]).

In [34], Wiśniewski classified Fano manifolds with index $i_F \geq (n + 1)/2$. Let us denote by $Q^j \subset \mathbb{P}^{j+1}$ the $j$-dimensional smooth projective quadric and by $T_{\mathbb{P}^l}$ the tangent bundle of $\mathbb{P}^l$.

**Theorem 3.1** ([34]) Let $F$ be a Fano manifold of dimension $n$ and index $i_F \geq (n + 1)/2$. Then $F$ verifies one of the following:

(i) $\rho(F) = 1$;
(ii) $n$ is even and $F \simeq \mathbb{P}^{n/2} \times \mathbb{P}^{n/2}$;
(iii) $n$ is odd and $F \simeq \mathbb{P}^{(n-1)/2} \times Q^{(n+1)/2}$;
(iv) $n$ is odd and $F \simeq \mathbb{P}(T_{\mathbb{P}^{(n+1)/2}})$;
(v) $n$ is odd, $\mathcal{O} = \mathcal{O}_{\mathbb{P}^{(n+1)/2}}$ and $F \simeq \mathbb{P}(\mathcal{O}(1) \oplus \mathcal{O}^{(n-1)/2})$.

Let us note that in case (iv) (resp. (v)) of the above theorem $F$ can be alternatively described as a smooth divisor of degree $(1, 1)$ in $\mathbb{P}^{(n+1)/2} \times \mathbb{P}^{(n+1)/2}$ (resp. as the blow-up of $\mathbb{P}^n$ along a linear $\mathbb{P}^{(n-3)/2}$).

Looking at the above list, we are able to classify fibre-like Fano manifolds with high index.

**Proposition 3.2** Let $F$ be a fibre-like Fano manifold of dimension $n \geq 4$, index $i_F \geq (n + 1)/2$ and $\rho(F) > 1$.

- If $n$ is even then $F$ is isomorphic to $F \simeq \mathbb{P}^{n/2} \times \mathbb{P}^{n/2}$.
- If $n$ is odd then $F$ is isomorphic to $F \simeq \mathbb{P}(T_{\mathbb{P}^{(n+1)/2}})$.

**Proof** Use Corollary 1.6 to show that cases (iii) and (v) are not fibre-like: (iii) is clear, while (v) comes with a divisorial contraction to $\mathbb{P}^n$ and a fibration to $\mathbb{P}^{(n+1)/2}$. Fibre-likeness of (ii) is a consequence of Theorem 1.4, where $G = \mathbb{Z}/2\mathbb{Z}$ exchanges the two factors, and case (iv) follows by Corollary 1.5. □

In [22], Kobayashi and Ochiai proved that $i_F \leq n + 1$, where $n = \dim X$ and equality holds if and only if $F \cong \mathbb{P}^n$. They also showed that $i_F = n$ if and only if $F$ is a quadric hypersurface. Fano manifolds with index $n - 1$ are called del Pezzo manifolds and they have been classified by Fujita [16] and [17], while Fano manifolds with index $n - 2$ are called Mukai manifolds and their classification appeared in [26]. In dimension $n \geq 3$, del Pezzo manifolds have index $i_F \geq (n + 1)/2$ and they have already been studied in Proposition 3.2. For $n \geq 5$, also Mukai manifolds are included in Wiśniewski’s list, so we only need to study the case $n = 4, i_F = 2$ (see [29, Table 12.7] for the complete list).

**Proposition 3.3** Let $F$ be a 4-dimensional fibre-like Fano manifold of index $i_F = 2$ and $\rho(F) > 1$. Then $F$ is isomorphic to one of the following:

(i) a double cover of $\mathbb{P}^2 \times \mathbb{P}^2$ branched along a degree-(2, 2) divisor;
(ii) an intersection of two degree-(1, 1) divisors in $\mathbb{P}^3 \times \mathbb{P}^3$;
(iii) $\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1$.

**Proof** We follow the enumeration in [29, Table 12.7 ] of the 18 families. Applying Corollary 1.6 to the cases.
we immediately see that they are not fibre-like. Cases

(10) and (12)

are also not fibre-like, since they are obtained as a blow-up of $Q^4$ but come with a 2-dimensional fibration over $\mathbb{P}^{n-2}$. Cases

(13) and (15)

are $\mathbb{P}^1$-bundles over $\mathbb{P}^3$ or $Q^3$ and the other ray of the nef cone corresponds to the contraction of the section. The case which requires more care is (11), in which case $F$ is isomorphic to the projectivisation of the null-correlation bundle over $\mathbb{P}^3$. Although the two extremal rays of the nef cone of $F$ both yield fibrations, the image of the fibration associated to the ray not inducing the bundle structure is the quadric $Q^3$, see [32, Proposition 3.4]. Hence, $F$ is not fibre-like.

We now prove fibre-likeness for the remaining cases. Case (18) (corresponding to case (iii) in our list), has an action of $S_4$ and is clearly fibre-like because of Theorem 1.4.

For Case (7) (corresponding to case (ii)), we can directly apply Corollary 1.5. Let us analyse now Case (4) (corresponding to case (i) in our list): it is obtained as a member of the linear system $|2H_1 + 2H_2|$ in the toric variety $Z$ with weight data

\[
\begin{array}{ccccccc}
 x_0 & x_1 & x_2 & y_0 & y_1 & y_2 & z \\
 1 & 1 & 1 & 0 & 0 & 0 & 1 \\
 0 & 0 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

Since $Z$ comes with a $\mathbb{Z}/2\mathbb{Z}$-action exchanging the divisors $H_1$ and $H_2$ we have $\dim \text{NS}(Z)^{\mathbb{Z}/2\mathbb{Z}} = 1$ and we can apply [13, Theorem 4.5] to conclude that case (i) is fibre-like. \qed

4 Fano manifolds with high Picard number

Fano manifolds of a given dimension form a bounded family, so their Picard number is bounded. In spite of this boundedness result, their classification in dimension at least 4 is an open and rather difficult problem. A first step towards such classification would be to identify an effective bound on the Picard number of those Fano manifolds that are not a product of lower dimensional manifolds. Already this simpler problem is actually quite difficult. So far, the only known examples of families of Fano manifolds of dimension $n \geq 4$, which are not product and have Picard number at least $n + 4$, are

(i) a birational model of the blow-up of $\mathbb{P}^n$ in $n + 3$ points in general position, with $n \geq 4$ and even;
(ii) a birational model of the blow-up of $\mathbb{P}^4$ in eight points in general position.
The first family appears in any even dimension, the second example is sporadic. In this section we are going to show that all these examples are fibre-like. The first family with \( n \) odd gives non-\( \mathbb{Q} \)-factorial Fano varieties of Picard rank 1, see [1, p. 3029]. We do not know if there exists a general connection between having high Picard number and being fibre-like.

The sporadic example is discussed in [10]. There the authors prove, following [27], that the Fano manifold under investigation is isomorphic to the moduli space of rank two vector bundles on a del Pezzo surface of degree one. Varying the stability conditions, the authors can explicitly describe the birational geometry of the Fano manifolds. Thanks to this analysis, it is possible to describe the automorphism group of the manifold, and to show the following result.

**Theorem 4.1** ([10, Proposition 6.22]) *The Fano model of \( \mathbb{P}^4 \) blown-up in eight points in general position is fibre-like.*

We now focus on the first example. We use the results of [1] and [30, Section 3]. Take an even integer \( n = 2m \geq 2 \) and consider a smooth complete intersection \( Z \) of two quadrics in \( \mathbb{P}^{n+2} \). Let \( \mathcal{F}_{m-1} = \mathcal{F}_{m-1}(Z) \) be the variety of \((m-1)\)-planes in \( Z \). This is a smooth Fano variety of dimension \( n \). It can be seen as a higher dimensional generalisation of the quartic del Pezzo surface and has been extensively studied in the recent work [1].

The geometry of \( \mathcal{F}_{m-1} \) can be studied from another point of view, which we briefly recall here (see the survey [11] for the notation about Mori Dream Spaces). Let \( X_r^n \) be the blow-up of \( \mathbb{P}^n \) at \( r \) points in general position. Then it follows from [27] and [12, Theorem 1.3] that \( X \) is a Mori Dream Space if and only if \( n \) and \( r \) verify the inequality

\[
\frac{1}{n+1} + \frac{1}{r-n-1} > \frac{1}{2},
\]

(cf. [11, Example 3.6].

The manifolds appearing in Theorem 4.1 are, in this notation, obtained as Fano models of \( X^n_r \).

Look at \( X^{n+3}_r \), with \( n \geq 2 \) even. For this class, inequality (7) holds, so \( X^{n+3}_r \) is a Mori Dream Space and we can consider its Fano model \( F^{n+3}_r \). Bauer in [3] proved that \( X^{n+3}_r \) and \( \mathcal{F}_{m-1} \) are isomorphic in codimension one—see also [1, Theorem 1.4]. By [1, Remark 4.10] it follows that \( \mathcal{F}_{m-1} \) is actually isomorphic to \( F^{n+3}_r \). In [1, Proposition 7.1] the authors describe the automorphism groups of \( \mathcal{F}_{m-1} \) showing that

\[
(\mathbb{Z}/2\mathbb{Z})^{n+2} \subseteq \text{Aut}(\mathcal{F}_{m-1}) \subseteq W(D_{n+3}) \quad (= (\mathbb{Z}/2\mathbb{Z})^{n+2} \rtimes S_{n+2}),
\]

where \( W(D_{n+3}) \) is the Weyl group of automorphism of a \( D_{n+3} \)-lattice. The inclusion \((\mathbb{Z}/2\mathbb{Z})^{n+2} \subseteq \text{Aut}(\mathcal{F}_{m-1})\) is an actual equality for a general choice of \( \mathcal{F}_{m-1} \). The action of \((\mathbb{Z}/2\mathbb{Z})^{n+2}\) can be described by presenting \( Z \) as the locus

\[
\sum_{i=0}^{n+3} x_i^2 = \sum_{i=0}^{n+3} \lambda_i x_i^2 = 0.
\]
Then the group acts by changing the signs of the coordinates. We can use this to prove the following.

**Theorem 4.2** Let \( n = 2m \geq 4 \) be an integer. Then the smooth \( n \)-dimensional Fano variety \( F_{m-1}(Z) \) of \((m-1)\)-planes in the intersection of two quadrics \( Z \subset \mathbb{P}^{n+2} \) is fibre-like.

**Proof** Consider the isomorphism \( H^2(F_{m-1}, \mathbb{Z}) \simeq NS(F_{m-1}) \). The action of \( G := (\mathbb{Z}/2\mathbb{Z})^{n+2} \) via pseudo-automorphisms of \( X^n \) is explicitly described in [15, Sections 4.4–4.6] (see also [1, Remark 7.2]). Let \( x_0, \ldots, x_{n+2} \in \mathbb{P}^n \) be blown-up points; we can assume that the first \( n+1 \) are the coordinate points and

- \( x_{n+1} = [1 : \ldots : 1] \);
- \( x_{n+2} = [c_0 : \ldots : c_n] \).

The pseudo-automorphism \( \phi_{n+2,n+3} : X^n_{n+3} \to X^n_{n+3} \) is defined on \( \mathbb{P}^n \) as \( \rho \circ \iota \), where \( \iota : \mathbb{P}^n \to \mathbb{P}^n \) is the standard Cremona involution and \( \rho \) is the diagonal projective transformation \( [t_0 : \ldots : t_n] \mapsto [c_0 t_0 : \ldots : c_n t_n] \). Analogously, one defines \( \phi_{i,j} \) with \( i < j \), which exchanges the exceptional divisors of \( X^n_{n+3} \) and fixes \( K_{X^n_{n+3}} \). This implies that \( NS(X^n_{n+3})^G_\mathbb{Q} = \mathbb{Q} K_{X^n_{n+3}} \). Moreover, the analysis in [1, Proposition 5.4] implies that \( NS(X^n_{n+3})^G \simeq NS(F_{m-1})^G \). So we apply Theorem 1.4 to conclude. \( \Box \)

### 5 Open questions

We conclude this note with some questions regarding fibre-like varieties that are still open. Since all the examples of smooth toric fibre-like Fano varieties are vertex-transitive, we ask the following:

**Question 5.1** Is any fibre-like toric Fano manifold vertex-transitive?

Answering this question affirmatively would give a complete classification of fibre-like toric Fano manifolds.

On a different note, the study of fibre-like Fano varieties in positive characteristic seems to be still very far from being satisfactory.

After the recent developments for the MMP in positive characteristic for threefolds (cf. [4, 6, 20]), the picture that we delineated in the introduction holds almost in the same way in characteristic \( > 5 \) as long as we only focus in dimension 2 and 3. Hence, it is natural to try to extend the results in [13] to positive characteristic. If \( k \) is any algebraically closed field and \( F \) is a smooth Fano variety over \( k \), the definition of fibre-likeness still makes sense and one can in particular ask the following:

**Question 5.2** If \( \text{char} k = p > 0 \), are there sufficient or necessary conditions that determine whether a smooth Fano \( F \) is fibre-like?

At present time, the situation appears to be quite obscure: we do not even know if a del Pezzo surface of degree 8 is fibre-like in positive characteristic. The approach outlined in [13] relying on the study of a suitable monodromy action on the Néron–Severi does not generalize directly to this case.
Acknowledgements We would like to thank Cinzia Casagrande for interesting comments on this work and an anonymous referee for useful suggestions.
