KHOVANSKII BASES, HIGHER RANK VALUATIONS AND TROPICAL
GEOMETRY
KIJUMARS KAVEH AND CHRISTOPHER MANON

ABSTRACT. Given a finitely generated algebra $A$, it is a fundamental question whether $A$ has a full rank discrete (Krull) valuation $v$ with finitely generated value semigroup. We give a necessary and sufficient condition for this, in terms of tropical geometry of $A$. In the course of this we introduce the notion of a Khovanskii basis for $(A, v)$ which provides a framework for far extending Gröbner theory on polynomial algebras to general finitely generated algebras. In particular, this makes a direct connection between the theory of Newton-Okounkov bodies and tropical geometry, and toric degenerations arising in both contexts. We also construct an associated compactification of Spec $(A)$. Our approach includes many familiar examples such as the Gel’fand-Zetlin degenerations of coordinate rings of flag varieties as well as wonderful compactifications of reductive groups. We expect that many examples coming from cluster algebras naturally fit into our framework.

1. INTRODUCTION
It is an important question in commutative algebra and algebraic geometry whether a given finitely generated algebra has a full rank valuation with finitely generated value semigroup. The purpose of this paper is to give a necessary and sufficient condition for this in terms of tropical geometry. In the course of this, we introduce the notion of a Khovanskii
basis. Our approach includes many familiar examples from representation theory. We expect that many examples coming from cluster algebras naturally fit into our framework ([RW, GHKK]).

Before stating the main results of the paper, let us review some background material. Let \( A \) be a finitely generated \( k \)-algebra and domain with Krull dimension \( d \) over a field \( k \). We consider a discrete valuation \( v : A \setminus \{0\} \to \mathbb{Q}^r \), for some \( 0 < r \leq d \), which lifts the trivial valuation on \( k \) (here the additive group \( \mathbb{Q}^r \) is equipped with a group ordering \( \succ \), see Definition 2.1). The image \( S(A, v) \) of \( v \), that is, \( S(A, v) = \{ v(f) \mid 0 \neq f \in A \} \), is usually called the value semigroup of \( v \). It is a (discrete) additive semigroup in \( \mathbb{Q}^r \). The rank of the valuation \( v \) is the rank of the group generated by its value semigroup. The valuation \( v \) gives a filtration \( F_v = (F_v \geq a)_{a \in \mathbb{Q}^r} \) on \( A \), defined by:

\[
F_v \geq a = \{ f \in A \mid v(f) \geq a \} \cup \{0\}.
\]

(\( F_v \succ a \) is defined similarly.) The corresponding associated graded \( \text{gr}_v(A) \) is:

\[
\text{gr}_v(A) = \bigoplus_{a \in \mathbb{Q}^r} F_v \geq a / F_v \succ a.
\]

It is important to note that \( \text{gr}_v(A) \) is also a domain. For \( 0 \neq f \in A \) we can consider its image \( \bar{f} \) in \( \text{gr}_v(A) \), namely the image of \( f \) in \( F_v \geq a / F_v \succ a \) where \( a = v(f) \). The following is a central concept in the paper.

**Definition 1** (Khovanskii basis). A set \( B \subseteq A \) is a Khovanskii basis for \( (A, v) \) if the image of \( B \) in the associated graded \( \text{gr}_v(A) \) forms a set of algebra generators.

The case when our algebra \( A \) has a finite Khovanskii basis with respect to a valuation \( v \) is particularly desirable.

**Remark.** The main idea behind the definition of a Khovanskii basis is to obtain information about \( A \) from its associated graded algebra \( \text{gr}_v(A) \). This algebra can be regarded as a degeneration of \( A \) and is often simpler to work with, for example, \( \text{gr}_v(A) \) is graded by the value semigroup \( S = S(A, v) \). The case of main interest is when \( k \) is algebraically closed and \( v \) has full rank equal to \( d \). In this case the associated graded \( \text{gr}_v(A) \) is the semigroup algebra \( k[S] \), and hence is a subalgebra generated by monomials in a polynomial algebra. The existence of a finite Khovanskii basis then is equivalent to \( S \) being a finitely generated semigroup, in which case \( k[S] \) basically can be described by combinatorial data (see Section 2 and Proposition 2.4). Moreover, we have a degeneration of \( \text{Spec}(A) \) to the (not necessarily normal) toric variety \( \text{Spec}(k[S]) \).

The notion of a Khovanskii basis generalizes the notion of a SAGBI basis (also called a canonical basis in [Stu96]) which is used when \( A \) is a subalgebra of a polynomial algebra (see [RS90], [Stu96, Chapter 11] and also Remark 2.6). The name Khovanskii basis was suggested by B. Sturmfels in honor of A. G. Khovanskii’s contributions to combinatorial algebraic geometry and convex geometry. As far as the authors know, the present paper is the first paper which deals with the general notion of a Khovanskii basis. In this paper, after developing some basic facts about Khovanskii bases, we give a necessary and sufficient condition for existence of a finite Khovanskii basis for \( A \). We find that tropical geometry provides a suitable language for this condition (see Theorems 1 and 2 below).

There is a simple classical algorithm to represent every element in \( A \) as a polynomial in elements of a Khovanskii basis \( B \). This is usually known as the subduction algorithm.
(Algorithm 2.11). In general, given \((A, \nu)\) and \(f \in A\), it is possible that the subduction algorithm above does not terminate in finite time.\footnote{For example, take \(A = k[x]\) to be the polynomial algebra in one variable \(x\) and let \(\nu\) be the order of divisibility by \(x\). As a Khovanskii basis take \(B = \{x, x^2\}\). Then the subduction algorithm never stops for \(f = x\).} We will be interested in the cases where the subduction algorithm terminates. It is easily seen that this happens if the value semigroup \(S(A, \nu)\) is maximum well-ordered, i.e., every increasing chain in \(S(A, \nu)\) has a maximum (Proposition 2.12).

Let us say few words about the important case when \(A\) is positively graded, i.e. \(A = \bigoplus_{i \geq 0} A_i\). In this case, it is convenient to consider a valuation which also encodes information about the grading. More precisely, one would like to work with a valuation \(\nu : A \setminus \{0\} \to \mathbb{N} \times \mathbb{Q}^{r-1} \subset \mathbb{Q} \times \mathbb{Q}^{r-1}\) such that the first component of \(\nu\) is the degree. That is, for any \(0 \neq f \in A\) we have:

\[
\nu(f) = (\deg(f), \cdot).
\]

(1.1)

To \((A, \nu)\), with \(\nu\) as in (1.1), one associates a convex body in \(\mathbb{R}^{r-1}\) called a Newton-Okounkov body. This convex body encodes information about the Hilbert function of the algebra \(A\) (see Section 2.3 as well as [Oko03, LM09, KK12]). When \(k\) is algebraically closed and \(\nu\) has full rank, one shows that \(\Delta(A, \nu)\) is a convex body whose dimension is the degree of the Hilbert polynomial of \(A\) and its volume is the leading coefficient of this Hilbert polynomial (KK12, Theorem 2.31)\footnote{For this to be a valuation one should consider reverse ordering on the first coordinate. Alternatively, one can define \(\nu(f) = (-\deg(f), \cdot)\).}. In particular, if \(A\) is the homogeneous coordinate ring of a projective variety \(Y\), then the degree of \(Y\) is given by \(\dim(Y)\)! times the volume of the convex body \(\Delta(A, \nu)\) ([KK12, Corollary 3.2]). We would like to point out that the finite generation of the value semigroup \(S = S(A, \nu)\) implies that the corresponding Newton-Okounkov body is a rational polytope. Moreover, we have a toric degeneration of \(Y = \text{Proj}(A)\) to a (not-necessarily normal) toric variety \(\text{Proj}(k[S])\) (see [And13, Kav15, Section 7] and [Tec03].

We now explain the main results of the paper in some detail. Let us go back to the non-graded case and as before let \(A\) be a finitely generated \(k\)-algebra and domain with Krull dimension \(d\). Throughout we use the following notation and definitions: Let \(B = \{b_1, \ldots, b_n\}\) be a set of algebra generators for \(A\). The set \(B\) determines a surjective homomorphism \(\pi : k[x_1, \ldots, x_n] \to A\) defined by \(\pi(x_i) = b_i\), \(i = 1, \ldots, n\), which we refer to as a presentation of \(A\). Let \(I\) be the kernel of the homomorphism \(\pi\). Recall that the the tropical variety \(\mathcal{T}(I)\) is the set of all \(u \in \mathbb{Q}^n\) such that the corresponding initial ideal \(\text{in}_u(I)\) contains no monomials.\footnote{In fact, this statement is still true when \(A\) is not necessarily finitely generated as an algebra, but is contained in a finitely generated graded algebra.} One knows that the tropical variety \(\mathcal{T}(I)\) has a fan structure coming from the Gröbner fan of the homogenization of \(I\) ([MS15, Chapter 2]). In particular, each open cone \(C \subset \mathcal{T}(I)\) has an associated initial ideal \(\text{in}_C(I)\) (see Section 3).\footnote{The normalization of \(\text{Proj}(k[S])\) is the toric variety associated to the polytope \(\Delta(A, \nu)\).} We also recall that the Gröbner region \(\text{GR}(I)\) is the set of all \(u \in \mathbb{Q}^n\) for which there is a term order \(\succ\) with \(\text{in}_\succ(\text{in}_u(I)) = \text{in}_\succ(I)\). The Gröbner region always contains the negative orthant \(\mathbb{Q}^*_n\).\footnote{Conceptually it is more appropriate to talk about the tropical variety of an ideal in a Laurent polynomial algebra as opposed to a polynomial algebra. So in fact, instead of tropical variety of the ideal \(I\) one should consider the tropical variety of the ideal generated by \(I\) in the Laurent polynomial algebra \(k[x_1^\pm, \ldots, x_n^\pm]\). The tropical variety then encodes the behavior at infinity of the subscheme defined by this ideal in all possible toric completions of the ambient torus \(\mathbb{G}^*_m^n\).}
Let $C$ be an open cone in the tropical variety $\mathcal{T}(I)$. We say that $C$ is a prime cone if the corresponding initial ideal $\text{in}_C(I) \subset \mathbb{k}[x_1, \ldots, x_n]$ is a prime ideal. The first main result of the paper is the following (Section 5).

**Theorem 1.** For each prime cone $C$ in the tropical variety $\mathcal{T}(I)$ that lies in the Gröbner region $\text{GR}(I)$, there exists a discrete valuation $\nu : A \setminus \{0\} \to \mathbb{Q}^d$ such that $\mathcal{B}$ is a finite Khovanskii basis for $(A, \nu)$. Moreover, the rank of $\nu$ is at least the dimension of the prime cone $C$.

We call a valuation $\nu : A \setminus \{0\} \to \mathbb{Q}^r$ a subductive valuation if it possesses a finite Khovanskii basis and the subduction algorithm, with respect to this Khovanskii basis, always terminates (Definition 4.8). The next theorem is the second main result of the paper. It shows that, when $A$ is positively graded, subductive valuations are exactly valuations that arise from prime cones in the tropical variety.

**Theorem 2.** Let $A = \bigoplus_{i \geq 0} A_i$ be a finitely generated positively graded $\mathbb{k}$-algebra and domain. With notation as before, we have the following: A finite subset $\mathcal{B} \subset A$ consisting of homogeneous elements is a Khovanskii basis for a subductive valuation $\nu$ of rank $r$ if and only if the tropical variety $\mathcal{T}(I)$ contains a prime cone $C$ with $\dim(C) \geq r$.

In our setting, it is also natural to introduce a generalization of the notion of a standard monomial basis from Gröbner theory. We call a $\mathbb{k}$-vector space basis $\mathcal{B}$ for $A$ an adapted basis for $(A, \nu)$ if the image of $\mathcal{B}$ in the associated graded algebra $\text{gr}_\nu(A)$ forms a vector space basis for this algebra. One can perform a vector space analogue of the subduction algorithm with respect to $\mathcal{B}$ (Algorithm 2.30). Subductive valuations that have adapted bases are particularly nice. We see that, when $A$ is positively graded, any subductive valuation has an adapted basis (Corollary 4.11).

In representation theory context, the (dual) canonical basis of Kashiwara-Lusztig provides an important example of an adapted basis for the algebra of unipotent invariants on a reductive group. Other variants of adapted bases in representation theory have been studied by Feigin, Fourier, and Littelmann in [FFL], where they are called essential bases (see Example 2.30). These are the technical heart of the paper. A central concept in these constructions (and in fact in the whole paper) is that of a weight valuation introduced in Section 2.4. Below we briefly explain what a weight valuation is, and summarize the results of Sections 4 and 6 in a couple of theorems.

In the classical Gröbner theory, one defines the initial form in $\text{in}_u(f)$ of a polynomial $f \in \mathbb{k}[x_1, \ldots, x_n]$ with respect to a weight vector $u \in \mathbb{Q}^n$. This in turn gives a valuation $\nu_u : \mathbb{k}[x_1, \ldots, x_n] \setminus \{0\} \to \mathbb{Q}$. We use an extension of this notion and for any integer $r > 0$ and an $r \times n$ matrix $M \in \mathbb{Q}^{r \times n}$, we define a valuation $\nu_M : \mathbb{k}[x_1, \ldots, x_n] \setminus \{0\} \to \mathbb{Q}^r$ (see Section 4.1). We can then consider the pushforward of $\nu_M$ via the map $\pi : \mathbb{k}[x_1, \ldots, x_n] \to A$ to obtain a map $\nu_M : A \to \mathbb{Q}^r \cup \{\infty\}$ (Definition 4.1). In general the map $\nu_M$ is only a quasivaluation (see Section 2.4). We call a quasivaluation of the form $\nu_M$ a weight quasivaluation. We remark that when the associated initial ideal $\text{in}_M(I)$ is prime then $\nu_M$

---

7By abuse of terminology, occasionally we may refer to a closed cone as a prime cone, in which case we mean that its relative interior is a prime cone.

8Throughout the paper we will only be interested in $M$ such that $\nu_M(f) \neq \infty$, for all $0 \neq f$.

9Recall that a quasivaluation $\nu$ is defined with the same axioms as a valuation except that $\nu(fg) \geq \nu(f) + \nu(g)$. Some authors use the term semivaluation instead of quasivaluation.
is indeed a valuation (Lemma \[4.4\]). The following key statement in the paper relates the notions of a subductive valuation and a weight valuation (Lemma \[4.10\], see also Theorem \[2.16\]):

**Lemma 3.** A subductive valuation \( v : A \setminus \{0\} \to Q^r \) with a Khovanskii basis \( B = \{b_1, \ldots, b_n\} \) coincides with the weight valuation \( v_M \) where \( M \in Q^{r \times n} \) is the matrix whose column vectors are \( v(b_1), \ldots, v(b_n) \).

The next theorem is about constructing valuations from prime cones (see Section \[5\]).

**Theorem 4.** Let \( C \subset T(I) \) be a prime cone that lies in the Gröbner region \( GR(I) \). Let \( u = \{u_1, \ldots, u_r\} \subset C \) be a collection of rational vectors that span a real vector space of maximal dimension \( \dim(C) \). Let \( M \in Q^{r \times n} \) be the matrix whose row vectors are \( u_1, \ldots, u_r \). Let \( v_M : A \setminus \{0\} \to Q^r \) be the weight quasivaluation associated to \( M \). Then \( v_M \) is a valuation and the following hold:

1. \( gr_v(M) \cong k[x_1, \ldots, x_n]/\text{in}_C(I) \).
2. \( M \) coincides with the matrix:
   \[
   M_u = \begin{bmatrix}
   v_{u_1}(b_1) & \cdots & v_{u_1}(b_n) \\
   \vdots & \ddots & \vdots \\
   v_{u_r}(b_1) & \cdots & v_{u_r}(b_n)
   \end{bmatrix},
   \]
   where, for every \( i \), \( v_{u_i} \) is the weight quasivaluation on \( A \) associated to the weight vector \( u_i \).
3. The value semigroup \( S(A, v_M) \) is generated by the columns of the matrix \( M \).
4. The valuation \( v_M \) has an adapted basis which can be taken to be a standard monomial basis for a maximal cone in the Gröbner fan of \( I \) containing \( C \). In particular, \( v_M \) is a subductive valuation.

We remark that if \( C \) is maximal (i.e., it has dimension \( d = \dim(A) \)) then \( \text{in}_C(I) \) is a prime binomial ideal. We also note that by Theorem \[4.11\], the associated graded of the valuation \( v_M \) only depends on the cone \( C \). That is, given \( C \), it is possible to find many valuations \( v_M \) on \( A \) with the same associated graded algebra.

As a corollary of Theorem \[4\], we obtain the following.

**Corollary 5.** When \( A \) is positively graded and \( B \) consists of homogeneous elements of degree 1, we can choose \( u \) so that the first row of \( M \) is \((-1, \ldots, -1)\). One observes that in this case, after dropping a minus sign, the valuation \( v_M \) is as in \[1.1\] and the Newton–Okounkov body \( \Delta(A, v_M) \) is the convex hull of the \( v_M(b_i) \). In particular, when the cone \( C \) is maximal, the degree of \( Y = \text{Proj}(A) \) is equal to \( \text{dim}(Y)! \) times the volume of this convex hull.

Conversely, any weight valuation comes from a prime cone in the tropical variety in the following sense (see Section \[6\]).

**Theorem 6.** Let \( v = v_M : A \setminus \{0\} \to Q^r \) be a weight valuation with weighting matrix \( M \in Q^{r \times n} \) corresponding to a presentation \( A \cong k[x_1, \ldots, x_n]/I \) (recall that we assume \( v_M(f) \neq \infty \) for all \( 0 \neq f \in A \)). Then there is a prime cone \( C_v \subset T(I) \) such that:

\[
k[x_1, \ldots, x_n]/\text{in}_{C_v}(I) \cong gr_v(A).
\]

In particular, in light of Lemma \[3\], there exists a prime cone \( C_v \) for any subductive valuation \( v \) on \( A \).
In Section 4, we study a compactification $X_u$ of $X = \text{Spec}(A)$ by boundary components associated to a linearly independent set $u = \{u_1, \ldots, u_r\} \subset C$ where $C$ is a prime cone of dimension $r$ in the tropical variety $\mathcal{T}(I)$. We show that under mild conditions, the divisor $D_u = X_u \setminus X$ is of combinatorial normal crossings type (ST08).

**Theorem 7.** Let $X = \text{Spec}(A)$ and $C$ be a prime cone whose relative interior intersects the negative part $\mathcal{T}(I)^- = \mathcal{T}(I) \cap \mathbb{Q}_{\leq 0}^n$ of the tropical variety of an ideal $I$. Let $u = \{u_1, \ldots, u_r\} \subset C$ be a choice of $r$ linearly independent vectors. Let $M \in \mathbb{Q}^{r \times n}$ be the corresponding weighting matrix, i.e. the rows of $M$ are $u_1, \ldots, u_r$, and let $\mathbf{v}_M$ be its associated valuation. Then there is a compactification $X \subset X_u$ of combinatorial normal crossings type whose boundary is a union of $r$ reduced, irreducible divisors $D_1, \ldots, D_r$. The valuation $\mathbf{v}_M$ can be recovered from this boundary divisor in the sense that for any member $b \in B \subset A$ of an adapted basis $B$, we have $\mathbf{v}_M(b) = (\text{ord}_{D_1}(b), \ldots, \text{ord}_{D_r}(b))$.

**Remark.** A choice of ordering of the elements of $u$ which in turn determines $M$ is given by any ordering on the irreducible components $D_1, \ldots, D_r$. This can be used to define a flag of subvarieties in $X_u$:

$$D_1 \cap \cdots \cap D_r \subset \cdots \subset D_1 \cap D_2 \subset D_1.$$

The valuation $\mathbf{v}_M$ coincides with the valuation associated to the above flag of subvarieties (see [KK12] Example 2.13 or [LM09] for the notion of the valuation associated to a flag of subvarieties).

**Remark.** The above construction includes some well-known compactifications, and in particular the wonderful compactification of an adjoint group (see Example 8.1). More precisely, let $G$ be an adjoint group with weight lattice $\Lambda$ and semigroup of dominant weights $\Lambda^+$. One defines a natural valuation on the coordinate ring $k[G]$ as follows. Consider the isotypic decomposition $k[G] = \bigoplus_{\lambda \in \Lambda^+} (V_\lambda \otimes V_\lambda^*)$ for the left-right $(G \times G)$-action. Fix an ordering of fundamental weights. This defines a lexicographic ordering on the weight lattice $\Lambda$ of $G$. For $f \in k[G]$ let us write $f = \sum_{\lambda} f_\lambda$ as the sum of its isotypic components and define $\mathbf{v}(f) = \min\{\lambda \mid f_\lambda \neq 0\}$. One verifies that this gives a $(G \times G)$-invariant valuation $\mathbf{v} : k[G] \setminus \{0\} \to \Lambda$. Also one can see that this valuation is of the form $\mathbf{v}_M$ (as in Theorem 4) and comes with an associated compactification (as in Theorem 7). Moreover, from Brion’s description of the total coordinate ring of a wonderful compactification ([Bri07]) it follows that the compactification associated to $\mathbf{v}$ is the wonderful compactification of $G$. Theorem 7 then implies that the valuation $\mathbf{v}$ corresponds to a flag of $(G \times G)$-orbit closures in the wonderful compactification. One can extend this example to other spherical homogeneous spaces.

**Remark.** In [GHKK], Gross, Hacking, Keel, and Kontsevich construct general toric degenerations in the context of cluster algebras and define and study related compactification constructions. This is also present in the related work of Rietsch and Williams on the Grassmannian variety $\text{Gr}_k(\mathbb{C}^n)$ ([RW]). The paper [BFF+] considers certain Khovanskii bases for the Plücker algebras of $\text{Gr}_2(\mathbb{C}^n)$ and $\text{Gr}_3(\mathbb{C}^n)$ in connection with [RW]. We suspect that these constructions agree with variants of the ones we define here when the cone $C \subset \mathcal{T}(I)$ is chosen with regard to a Khovanskii basis of cluster monomials. More specifically, in light of the results in [BFF+], we think that the valuation on Plücker algebra of $\text{Gr}_2(\mathbb{C}^n)$ associated to a plabic graph (as constructed in [RW]) coincides with the valuation constructed from a prime cone (in the tropical Grassmannian) as in Theorem 4.
We would like to mention the recent paper [KU] as well. In this paper the authors also make a connection, but in a quite different direction than ours, between the theory of Newton-Okounkov bodies and tropical geometry.

Finally, we say a few words about tropical sections and existence of finite Khovanskii bases. Recall that the tropical variety $T(I)$ can be realized as the image of the Berkovich analytification $\text{Spec}(A)^{an}$ under a tropicalization map $\phi_B$ ([Pay09], [MS15], Section 3.3). It is of interest in tropical geometry to know when the tropicalization map $\phi_B: \text{Spec}(A)^{an} \to T(I)$ has a section $s: U \to X^{an}$, for $U \subset T(I)$. In [GRW16], Gubler, Rabinoff, and Werner build off of work of Baker, Payne, and Rabinoff [BPR13] on curves, to show that such a section always exists over the locus of points with tropical multiplicity 1. Our Theorem 6 implies that the cone $C_v$ corresponding to a subductive valuation $v$ has such a section. In particular, following [GRW16, Section 10], a point $u \in C_v \subset T(I)$ lies under a strictly affinoid domain in the analytification $\text{Spec}(A)^{an}$ with a unique Shilov boundary point (the weight valuation $v_u$). In this sense, $C_v$ can be regarded as a cone in $\text{Spec}(A)^{an}$. With this in mind, we will explore the relationship between convex sets in the Berkovich analytification $\text{Spec}(A)^{an}$ and higher rank valuations in future work.

Theorem 4 states that a prime cone $C \subset T(I)$ can be used to produce a discrete valuation with a prescribed Khovanskii basis. This leads us to the following problem.

**Problem 1.** Given a projective variety $Y$, find an embedding of this variety into a projective toric variety so that the resulting tropicalization contains a prime cone of maximal dimension.

A positive resolution of Problem 1 in general would be useful for construction of toric degenerations. In particular, it would imply that the homogeneous coordinate ring of any projective variety has a subductive valuation with maximal rank and therefore a toric degeneration to the toric variety associated to the value semigroup of this valuation.

**Remark** (Polyhedral Newton-Okounkov bodies). Let us consider the graded case $A = \bigoplus_{i \geq 0} A_i$ and let us take a valuation $v$ as in (1.1) which encodes the degree function on $A$. It is immediate from definition that if the value semigroup $S(A,v)$ is finitely generated then the corresponding Newton-Okounkov body $\Delta(A,v)$ is a rational polytope. But it is easy to see that the other implication does not always hold, i.e. if $\Delta(A,v)$ is a rational polytope it does not imply that $S(A,v)$ is finitely generated. In fact, by the work [AKL14] (see also [Sep16]) one knows that for homogeneous coordinate rings of projective varieties (and more generally rings of sections of big line bundles) one can find valuations such that the corresponding Newton-Okounkov bodies are rational simplices.

Using results of Gubler, Rabinoff, and Werner [GRW16], a resolution of Problem 1 appears possible in the case that $U \subset \mathbb{G}_m^n$ is a very affine variety and $k$ a field of characteristic 0. First, one constructs a compactification $\tilde{X} \supset U$, and resolves it to a smooth normal crossings compactification using Hironaka’s strong resolution of singularities in characteristic 0 ([Hir64], [Kol07, Theorem 3.3]). By [GRW16] Theorems 8.4 and 9.5 (see also [Che]), this compactification produces a tropical skeleton in $\tilde{X}^{an}$, along with an embedding of an open subset of $U$ whose tropicalization “sees” this skeleton as a set of points with tropical multiplicity 1. This tropicalization then contains a prime cone $C$. With this in mind, it would be interesting to have a solution of the following problem.

**Problem 2.** Let $A$ be a finitely generated $k$-algebra and domain with Krull dimension $d$. Find an effective algorithm for constructing a valuation $v: A \setminus \{0\} \to \mathbb{Q}^d$ of maximal rank $d$ and with a finite Khovanskii basis.
In Section 8 we consider some examples of the main results of the paper. These include the Gel’fand-Zetlin bases for homogeneous coordinate rings of the Plücker embeddings of the Grassmannians and flag varieties. In this regard, we would also like to mention the related work \[\text{SX10}\] on Cox rings of del Pezzo surfaces.

**An Example.** Let $E \subset \mathbb{P}^2$ be the elliptic curve cut out by the homogeneous equation

$$y^2z - x^3 + 7xz^2 - 2z^3 = 0.$$  

Let us illustrate how to construct a subductive valuation (in particular with a finite Khovanovskii basis) for the homogeneous coordinate ring of $E$ using prime cones in its tropical variety as in Section 5. The tropical variety $T$ of $y^2z - x^3 + 7xz^2 - 2z^3$ is the union of the three half-planes $Q(1,1,1) + Q_{\geq 0}(1,0,0)$, $Q(1,1,1) + Q_{\geq 0}(0,1,0)$, and $Q(1,1,1) + Q_{\geq 0}(-2,-3,0)$ with initial forms $zy^2 - 2z^3$, $x^3 + 7xz^2 - 2z^3$, and $y^2z - x^3$, respectively.

**Figure 1.** The tropical variety $T/Q(1,1,1)$. The image of the cone $C$ is in the negative orthant.

The half-plane $C = Q(1,1,1) + Q_{\geq 0}(-2,-3,0)$ is the only prime cone, and by Theorem 2 it can be used to create a subductive valuation $v : \mathbb{k}[E] \setminus \{0\} \rightarrow \mathbb{Z}$. Using Section 5 we can construct this valuation by sending $x, y, z$ to the first, second and third columns of the following weighting matrix $M$ respectively:

$$M = \begin{bmatrix}
-1 & -1 & -1 \\
-2 & -3 & 0
\end{bmatrix}.$$  

We have obtained $M$ by taking its rows to be the vectors $(-1,-1,-1)$ and $(-2,-3,0) \in C$. This assignment is then extended linearly to all monomials in $x, y, z$, and the resulting set is lexicographically ordered. As a consequence the value semigroup $S(\mathbb{k}[E], v)$ is the $\mathbb{Z}_{\geq 0}$-span of the columns of $M$. The Newton-Okounkov cone $P(\mathbb{k}[E], v)$ is the convex hull of $S(\mathbb{k}[E], v)$ (see Figure 1). The Newton-Okounkov body $\Delta(\mathbb{k}[E], v)$ is the convex hull of the columns of $M$, this is an interval of length $3 = \deg(y^2z - x^3 + 7xz^2 - 2z^3)$ in $\{-1\} \times \mathbb{R}$.

From Section 7 we obtain a compactification $\bar{X}$ of the affine cone $\bar{E} = \text{Spec}(\mathbb{k}[E])$ associated to the choice of matrix $M$. The projective coordinate ring $\mathbb{k}[\bar{X}]$ given by this construction is presented by 7 parameters: $T$ and $Z$ have homogeneous degree 1, $x$ and $X$ have homogeneous degree 2, and finally $y, Y, Z$ have homogeneous degree 3. The ideal which vanishes on these parameters is generated by the following forms:
Figure 2. The Newton-Okounkov cone of \( k[E] \) with highlighted Newton-Okounkov body. The larger dots indicate members of \( S(k[E], v) \).

\[
\begin{align*}
&xY - Xy, \quad xZ - XY, \quad TX - xz, \quad TY - yz, \quad TZ - Yz, \\
&X^3 - Z^2 + 7Xz^4 - 2z^6, \quad xX^2 - yZ + 7Xz^3T - 2z^5T \\
x^2X - yZ + 7Xz^2T^2 - 2z^4T^2, \quad x^2X - Z^2 + 7Xz^2T^2 - 2z^4T^2, \quad x^3z - yY + 7XzT^3 - 2z^3T^3.
\end{align*}
\]

The polytope bordered by the dotted line in Figure 2 is the Newton-Okounkov polytope of the compactification that appears in Section 7 (see (7.3)). The above relations were obtained by lifting a Markov basis of a certain toric ideal.

The compactifying divisor \( D = X \setminus \hat{E} \) is the locus of the equation \( T = 0 \). It has two components \( D_1, D_2 \) cut out by the ideals \( I_1 = \langle T, z \rangle \) and \( I_2 = \langle T, x, y, Y \rangle \) respectively.

**Acknowledgement.** We would like to thank Diane Maclagan, Bernd Sturmfels, Dave Anderson, Alex Küronya and Michel Brion for useful comments on a preliminary version of this paper. In fact, this paper was inspired by a question that Bernd asked the authors about a connection between toric degenerations arising in tropical geometry and the theory of Newton-Okounkov bodies. We also thank Angie Cueto and Joseph Rabinoff for explaining their work to us. The authors are also grateful to the Fields Institute for Research in Mathematical Sciences for hosting the program in Combinatorial Algebraic Geometry. Some of this work was done during this program. Finally, thanks to Sara Lamboglia and Kalina Mincheva and several other participants of the Apprenticeship Program at the Fields Institute for helpful discussions.

**Notation.**
- \( k \), a field which we take to be our base field throughout the paper. In some places we may require that \( k \) is algebraically closed.
- \( k[x] \), the polynomial ring over \( k \) associated to a finite set of indeterminates \( x = (x_1, \ldots, x_n) \).
- \( A \), a finitely generated \( k \)-algebra and domain with Krull dimension \( d = \dim(A) \). We sometimes assume that \( A \) is \( \mathbb{Z}_{\geq 0} \)-graded.
• \( v : A \setminus \{0\} \rightarrow \mathbb{Q}^r \), a discrete valuation on \( A \) (see Definition 2.1). The case of main interest is when \( v \) has one-dimensional leaves, which in turn implies that it has full rank \( d = \dim(A) \).

• \( S(A,v) \), the values semigroup of \( (A,v) \) and \( P(A,v) \) the Newton-Okounkov cone of \( (A,v) \), i.e. the closure of convex hull of \( S(A,v) \cup \{0\} \). Also when \( A \) is positively graded the corresponding Newton-Okounkov body is denoted by \( \Delta(A,v) \) (see Sections 2.1 and 2.3).

• \( B = \{b_1, \ldots, b_n\} \) a set of \( k \)-algebra generators for \( A \).

• \( I \subset k[x] \), an ideal usually taken to be the kernel of a surjective homomorphism \( \pi : k[x] \rightarrow A \) given by \( x_i \mapsto b_i \). We refer to \( \pi \) or \( k[x]/I \cong A \) as a presentation of \( A \).

• \( M \in \mathbb{Q}^{r \times n} \), a weighting matrix for the parameters in \( x \), inducing an initial term valuation \( v_M : k[x] \setminus \{0\} \rightarrow \mathbb{Q}^r \) (see Section 4.1).

• \( v_M : A \setminus \{0\} \rightarrow \mathbb{Q}^r \), the quasivaluation on \( A \) obtained by pushforward of \( \tilde{v}_M \) via the homomorphism \( \pi \) (see Definition 2.25 and Section 4.1).

• \( \text{GR}(I) \), the Gröbner region of an ideal \( I \).

• \( \Sigma(I) \), the Gröbner fan of an ideal \( I \).

• \( T(I) \), the tropical variety of an ideal \( I \) (see Definition 3.13).

2. Valuations on algebras and Khovanskii bases

In this section we introduce some of the basic terminology and results concerning valuations and we develop a general theory of Khovanskii bases. In what follows \( A \) is a finitely generated \( k \)-algebra and domain with Krull dimension \( d \).

2.1. Preliminaries on valuations. Throughout the paper, a (linearly) ordered group is an Abelian group \( (\Gamma,+) \) equipped with a total ordering \( \succ \) which respects the group operation. Primarily we work with a discrete subgroup of a rational vector space \( \mathbb{Q}^r \) with some linear ordering. By the Hahn embedding theorem ([Gra56]), there is always an embedding of linearly ordered groups \( \eta : \mathbb{Q}^r \rightarrow \mathbb{R}^r \), where \( \mathbb{R}^r \) is given the standard lexicographic ordering, consequently we may treat any linear ordering by considering the lexicographic case.

Let \( (\Gamma, \succ) \) be a linearly ordered group.

Definition 2.1 (Valuation). We recall that a function \( v : A \setminus \{0\} \rightarrow \Gamma \) is a valuation over \( k \) if it satisfies the following axioms:

1. For all \( 0 \neq f, g \in A \) with \( 0 \neq f + g \) we have \( v(f+g) \preceq \min\{v(f),v(g)\} \).

2. For all \( 0 \neq f, g \in A \) we have \( v(fg) = v(f) + v(g) \).

3. For all \( 0 \neq f \in A \) and \( 0 \neq c \in k \) we have \( v(cf) = v(f) \).

Each valuation \( v \) on \( A \) naturally gives a \( \Gamma \)-filtration \( F_v = (F_{v \geq a})_{a \in \Gamma} \) on \( A \). Namely, for \( a \in \Gamma \) we define:

\[ F_{v \geq a} = \{ f \in A \mid v(f) \geq a \} \cup \{0\}. \]

\( (F_{v \geq a}) \) is defined similarly. Clearly \( F_{v \geq a} \) and \( F_{v \succ a} \) are vector subspaces of \( A \).

If the following extra property is satisfied we say that \( v \) has one-dimensional leaves:

4. For every \( a \in \Gamma \) the quotient vector space:

\[ F_{v \geq a}/F_{v \succ a}, \]

is at most 1-dimensional.

Let \( K \) denote the quotient field of \( A \). Let \( R_v = \{ f \in K \mid v(f) \geq 0 \} \cup \{0\}, \ m_v = \{ f \in K \mid v(f) > 0 \} \cup \{0\} \) and \( k_v = R_v/m_v \) denote the valuation ring of \( v \), its maximal ideal and its residue field respectively. Clearly \( k_v \) contains \( k \). It is straightforward to verify that a
valuation \( v \) has one-dimensional leaves if and only if the residue field extension is trivial, that is, \( k_p = k \).

Below we give some examples of valuations. These contain some cases of interest in computational algebra, algebraic geometry and representation theory, and partly motivated the present work.

**Example 2.2.** (1) Let \( A \) be graded by an ordered group \( \Gamma \), i.e. \( A = \bigoplus_{g \in \Gamma} A_g \). Using the \( \Gamma \)-grading we can define a valuation \( v : A \setminus \{0\} \to \Gamma \) as follows. Take \( 0 \neq f \in A \) and let \( f = \sum_{g \in \Gamma} f_g \) be its decomposition into homogeneous components. We then define:

\[
v(f) = \text{MIN}\{ g \mid f_g \neq 0 \}.
\]

We call the valuation \( v \) constructed in this way a *grading function*. It is easy to see that the associated graded algebra \( \text{gr}_v(A) \) is canonically isomorphic to \( A \).

(2) Consider the algebra of polynomials \( k[x] \) in \( n \) indeterminates \( x = (x_1, \ldots, x_n) \). It is graded by the semigroup \( \mathbb{Z}_{\geq 0}^n \subset \mathbb{Z}^n \). Fix a group ordering \( \succ \) on \( \mathbb{Z}^n \). As a particular case of the part (1) above, \( \succ \) gives rise to a valuation \( v : k[x] \setminus \{0\} \to \mathbb{Z}_{\geq 0}^n \). We call it the *lowest term* or *minimum term valuation*. One verifies that \( v \) is a valuation with one-dimensional leaves.

(3) More generally, let \( X \) be a \( d \)-dimensional variety defined over \( k \). Take a smooth point \( p \in X \) and let \( u_1, \ldots, u_d \) be a local system of parameters in \( d \). Every rational function \( f \) regular at \( p \) can be expressed as a power series in the \( u_i \). Fixing a group ordering on \( \mathbb{Z}^d \), one can define \( v(f) \) as the minimum exponent appearing in the power series of \( f \). This extends to define a valuation (with one-dimensional leaves) on the field of rational functions \( K \) of \( X \).

(4) Yet more generally, instead of a system of parameters at a smooth point, one can associate a valuation to a flag of subvarieties in \( X \) (see [KK12, Example 2.13] and [LM09]).

(5) Let \( G \) be a connected reductive algebraic group defined over \( k \). Let \( X \) be an affine variety equipped with a \( G \)-action. Let \( \Lambda \) be the weight lattice of \( G \). One can decompose the coordinate ring \( A = k[X] \) as a direct sum \( \bigoplus_{\lambda \in \Lambda^+} A_{\lambda} \), where \( A_{\lambda} \) is the \( \lambda \)-isotypic component of \( A \), i.e. the sum of irreducible representations in \( A \) with highest weight \( \lambda \). Fix a group ordering \( \succ \) on \( \Lambda \). One usually would like to assume that this ordering refines the so-called dominant partial order. Given \( f \in A \) let us write \( f = \sum_{\lambda} f_{\lambda} \) with \( f_{\lambda} \in A_{\lambda} \). One can then define \( v(f) = \text{MIN}\{ \lambda \mid f_{\lambda} \neq 0 \} \) where the minimum is with respect to \( \succ \). This defines a valuation \( v : A \setminus \{0\} \to \Lambda^+ \). This valuation in general does not have one-dimensional leaves property.

For simplicity, in this section, we consider \( \Gamma \) to be the additive group \( \mathbb{Z}^r \), for some \( 0 < r \leq d \), equipped with a linear ordering \( \succ \) (e.g. a lexicographic order).

We denote by \( S = S(A, v) \) the *value semigroup* of \((A, v)\), namely:

\[
S = \{ v(f) \mid 0 \neq f \in A \}.
\]

Clearly \( S \) is an (additive) subsemigroup of \( \mathbb{Z}^r \). The *（rational）rank of the valuation \( v \) is the rank of the sublattice of \( \mathbb{Z}^r \) generated by \( S(A, v) \).

The following theorem shows that when \( k \) is algebraically closed, and the valuation \( v \) has full rank \( d = \text{dim}(A) \), then it automatically has one-dimensional leaves. It is an immediate corollary of Abhyankar’s inequality.

**Theorem 2.3.** Let \( k \) be algebraically closed and assume that \( v \) has full rank \( d = \text{dim}(A) \). Then \( v \) has one-dimensional leaves.
The next proposition states that if \( \nu \) is assumed to have one-dimensional leaves property (Definition \[2.1\] 4)) then the associated graded algebra \( \text{gr}_\nu(A) \) can be realized as the semigroup algebra of the value semigroup \( S = S(A, \nu) \). We omit the proof here (see [HG09, Remark 4.13]).

**Proposition 2.4.** If \( \nu \) has one-dimensional leaves property then \( \text{gr}_\nu(A) \) is isomorphic to the semigroup algebra \( \mathbb{k}[S] \) (note that we do not require \( S \) to be finitely generated). More generally, if \( R \) is a \( \mathbb{Z}^d \)-graded algebra such that for any \( a \in \mathbb{Z}^d \), the corresponding graded piece \( R_a \) is at most 1-dimensional, then \( R \) is isomorphic to the semigroup algebra \( \mathbb{k}[S] \) where \( S \) is the subsemigroup of \( \mathbb{Z}^d \) defined by \( S = \{a \in \mathbb{Z}^d \mid R_a \neq \{0\}\} \).

### 2.2. Khovanskii bases and subduction algorithm.

The following definition is one of the key definitions in the paper. It generalizes the notion of a SAGBI basis (also called a Khovanskii bases and subduction algorithm).

**Definition 2.5** (Khovanskii basis). We say that \( B \subset A \) is a **Khovanskii basis** for \((A, \nu)\) if the image of \( B \) in \( \text{gr}_\nu(A) \) is a set of algebra generators for \( \text{gr}_\nu(A) \).

The name Khovanskii basis was suggested by B. Sturmfels in honor of A. G. Khovanskii’s influential contributions to combinatorial commutative algebra.

**Remark 2.6.** Let \( A \) be a subalgebra of a polynomial algebra \( \mathbb{k}[x] \). A Khovanskii basis for a lowest term valuation, as in Example \[2.2\] 2), is usually called a **SAGBI basis**, which stands for **Subalgebra Analogue of Gröbner Basis for Ideals** (see [RS90, Stu96 Chapter 11]). So the theory of Khovanskii bases far generalizes that of SAGBI bases.

Below are two examples of algebras with valuations which have finite Khovanskii bases.

**Example 2.7.** (1) Take the standard lexicographic order \( \succ \) on \( \mathbb{Z}^n \), that is, \( e_1 \succ \cdots \succ e_n \) where \( \{e_1, \ldots, e_n\} \) is the standard basis. Let \( \nu \) be the lowest term valuation on the polynomial algebra \( \mathbb{k}[x] \) as defined in Example \[2.2\] 2). Let \( A = \mathbb{k}[x]^{S_n} \) be the subalgebra of symmetric polynomials. It is well-known that this algebra is freely generated by the elementary symmetric polynomials. One verifies that the value semigroup \( S(A, \nu) \) is \( \{\{a_1, \ldots, a_n\} \in \mathbb{Z}^n_{\geq 0} \mid a_1 \leq \cdots \leq a_n\} \) which is a finitely generated semigroup. In fact, the elementary symmetric polynomials form a finite Khovanskii basis for \((A, \nu)\).

(2) Let \( G \) be a connected reductive algebraic group and \( X \) an affine variety with an algebraic action of \( G \). As in Example \[2.2\] 5), let \( \nu \) be the valuation on the coordinate ring \( A = \mathbb{k}[X] \) and with values in the weight lattice \( \Lambda \) (with respect to a group ordering \( \succ \) on \( \Lambda \)). One shows that if \( \succ \) refines the so-called dominant partial order on \( \Lambda \) then the associated graded \( \text{gr}_\nu(A) \) is the so-called horospherical degeneration of \( A \). This is known to be a finitely generated algebra and thus \((A, \nu)\) has a finite Khovanskii basis. As mentioned before, in general the valuation \( \nu \) does not have full rank. In [Kav13 Section 8], it is shown that when \( X \) is a spherical \( G \)-variety then the valuation \( \nu \) can be naturally extended to a full rank valuation \( \tilde{\nu} \) on \( A \) such that the semigroup \( S(A, \tilde{\nu}) \) is finitely generated. In other words, \((A, \tilde{\nu})\) also has a finite Khovanskii basis. This recovers the toric degeneration results in [Cal02, AB04, Kav05].

**Remark 2.8.** The idea behind the definition of a Khovanskii basis is to reduce computations in the algebra \( A \) to computations in \( \text{gr}_\nu(A) \). The algebra \( \text{gr}_\nu(A) \) can be regarded as a degeneration of \( A \) and in principle has a simpler structure than that of \( A \), for example, it...
is graded by the semigroup \( S = S(A, v) \subset \mathbb{Z}' \). The case of main interest is when \( v \) has one-dimensional leaves in which case \( \text{gr}_v(A) \cong k[S] \) is a semigroup algebra (Proposition 2.4). Doing computation in the algebra \( k[S] \) is more or less equivalent to doing computation in the semigroup \( S \) which we regard as a combinatorial object.

Here are two examples where the value semigroup \( S(A, v) \) and hence the associated graded \( \text{gr}_v(A) \) are not finitely generated.

**Example 2.9.** (1)(Göbel) Consider the polynomial algebra \( k[x_1, x_2, x_3] \). As in Example 2.2(2), let \( v \) be the lowest term valuation with respect to the lexicographic order \( e_3 > e_2 > e_1 \).

Let \( A = k[x_1, x_2, x_3]^{A_3} \) be the subalgebra of invariants of the alternating group \( A_3 \). One shows that the value semigroup \( S(A, v) \subset \mathbb{Z}_{\geq 0}^3 \) is not finitely generated and hence \( (A, v) \) does not have a finite Khovanskii basis (see Göbel95 and also Stu96 Example 11.2).

(2) Let \( A \) be the homogeneous coordinate ring of an elliptic curve \( X \) sitting in \( \mathbb{P}^2 \) as the zero set of a cubic polynomial (in the standard form). Let \( v' = \text{ord}_p : A \setminus \{0\} \to \mathbb{Z} \) be the order of vanishing valuation at a general point \( p \in X \) and let \( v : A \setminus \{0\} \to \mathbb{Z}_{\geq 0} \times \mathbb{Z} \) be the valuation constructed out of \( v' \) and degree (as in (1.1)). One verifies that \( S(A, v) = \{(i, a) \mid i \in \mathbb{Z}_{\geq 0}, 0 \leq a < 3i\} \) which is a not finitely generated semigroup. On the other hand, if we take \( p \) to be the point at infinity then this semigroup can be seen to be finitely generated (see [LM99] Example 1.7 and [And13] Example 6).

We will use the following notation. For \( 0 \neq h \in A \) we let \( h \) denote its image in \( \text{gr}_v(A) \), i.e. the image of \( h \) in the quotient \( F_{v \geq a}/F_{v > a} \) where \( a = v(h) \). Clearly, \( h \) is a homogeneous element with degree \( a \).

The next lemma shows that from a Khovanskii basis one can recover the value semigroup \( S(A, v) \) (for a valuation \( v \) with one-dimensional leaves property this also follows from Proposition 2.4).

**Lemma 2.10.** Let \( B \) be a Khovanskii basis for \( (A, v) \). Then the set of values \( \{v(b) \mid b \in B\} \) generates \( S(A, v) \) as a semigroup.

**Proof.** Recall that \( \text{gr}_v(A) \) is an \( S(A, v) \)-graded algebra. Let \( 0 \neq f \in A \) with \( v(f) = a \). Since \( B \) is a Khovanskii basis we can write \( f \) as a polynomial \( \sum_{\alpha=(a_1, \ldots, a_n)} c_\alpha b_1^{a_1} \cdots b_n^{a_n} \), for some \( b_1, \ldots, b_n \in B \). Moreover, since \( f \) and the \( b_i \) are homogeneous, we can assume that for every \( \alpha \), with \( c_\alpha \neq 0 \), the corresponding term \( c_\alpha b_1^{a_1} \cdots b_n^{a_n} \) has degree \( a \). That is, \( a = \sum_{\alpha} \alpha_i v(b_i) \). This finishes the proof. \( \square \)

Whenever we have a Khovanskii basis \( B \), we can represent the elements of the algebra \( A \) as polynomials in the elements of \( B \) using a simple classical algorithm usually known as the subduction algorithm.

**Algorithm 2.11** (Subduction algorithm). Input: A Khovanskii basis \( B \subset A \) and an element \( 0 \neq f \in A \). Output: A polynomial expression for \( f \) in terms of a finite number of elements of \( B \).

1. Since the image of \( B \) in \( \text{gr}_v(A) \) generates this algebra, we can find \( b_1, \ldots, b_n \in B \) and a polynomial \( p(x_1, \ldots, x_n) \) such that \( f = p(b_1, \ldots, b_n) \). Thus we either have \( f = p(b_1, \ldots, b_n) \) or \( v(f - p(b_1, \ldots, b_n)) > v(f) \).

2. If \( f = p(b_1, \ldots, b_n) \) we are done. Otherwise replace \( f \) with \( f - p(b_1, \ldots, b_n) \) and go to the step (1).

We have the following easy but useful proposition.
Proposition 2.12. Suppose the value semigroup \( S = S(A, \nu) \) is maximum well-ordered, i.e. every subset of \( S \) has a maximum element with respect to the total order \( \succ \). Then for any \( 0 \neq f \in A \) the subduction algorithm (Algorithm 2.11) terminates after a finite number of steps.

A large class of examples where the maximum well-ordered assumption is satisfied are homogeneous coordinate rings of projective varieties. Below are some general situations where one can guarantee termination of subduction algorithm in finite time.

Example 2.13. (1) Let \( A = \bigoplus_{i \geq 0} A_i \) be a positively graded algebra such that for every \( i \), \( \dim_k(A_i) < \infty \) (for example this is the case if \( A_0 = k \)). Also let \( \nu : A \setminus \{0\} \rightarrow \mathbb{Z}^r \) be a valuation on \( A \) which refines the degree. That is, for any \( 0 \neq f_1, f_2 \in A, \deg(f_1) < \deg(f_2) \) implies that \( \nu(f_1) \succ \nu(f_2) \) (note the switch). We say that such a valuation is homogeneous with respect to the grading of \( A \). One shows that under these assumptions the value semigroup \( S(A, \nu) \) is maximum well-ordered.

(2) Let \( A = \bigoplus_{g \in \Gamma} A_g \) be an algebra graded by an abelian group \( \Gamma \) and such that for every \( g \in \Gamma, \dim_k(A_g) < \infty \). Let \( \nu \) be a valuation on \( A \) and \( B \) a Khovanskii basis for \( (A, \nu) \) consisting of \( \Gamma \)-homogeneous elements. Then the subduction algorithm terminates for any \( 0 \neq f \in A \).

For the rest of this subsection we assume that \( S(A, \nu) \) is maximum well-ordered and hence the subduction algorithm for \( (A, \nu, B) \) always terminates.

It is a desirable situation to have a finite Khovanskii basis. Below we explain how to find a Khovanskii basis provided that we know such a basis exists (Algorithm 2.17). The algorithm can be thought of as a variant of the Buchberger algorithm for finding a Gröbner basis for an ideal in a polynomial ring.

Before we present the algorithm, we need some preparation. The next lemma and theorem give a necessary and sufficient condition for a set of algebra generators to be a Khovanskii basis. These are extensions of similar statements from [Stu96, Chapter 11] to the setup of Khovanskii bases.

Let \( B = \{b_1, \ldots, b_n\} \subset A \) be a subset that generates \( A \) as an algebra. Let \( a_i = \nu(b_i), i = 1, \ldots, n \) and put \( A = \{a_1, \ldots, a_n\} \). Let \( k[x] \) denote the polynomial algebra in indeterminates \( x = (x_1, \ldots, x_n) \). Consider the surjective homomorphism \( k[x] \rightarrow A \) given by \( x_i \mapsto b_i \). We let \( I \) be the kernel of this homomorphism. Also we consider the homomorphism \( k[x] \rightarrow \text{gr}_\nu(A) \) given by \( x_i \mapsto b_i, i = 1, \ldots, n \), where as before \( b_i \) denotes the image of \( b_i \) in \( \text{gr}_\nu(A) \). We denote the kernel of the homomorphism \( k[x] \rightarrow \text{gr}_\nu(A) \) by \( I_B \).

Remark 2.14. If we assume that the valuation \( \nu \) has one-dimensional leaves, then by Proposition 2.14 the image of the homomorphism \( k[x] \rightarrow \text{gr}_\nu(A) \) is isomorphic to the semigroup algebra \( k[S'] \) where \( S' \) is the semigroup generated by the values \( \nu(b_i), i = 1, \ldots, n \). Thus, we see that the ideal \( I_B \) is a toric ideal and hence generated by binomials. When \( B \) is a Khovanskii basis, the semigroup \( S' \) coincides with the whole value semigroup \( S = S(A, \nu) \) and \( k[x]/I_B \cong k[S] \).

Let \( M = (a_1, \ldots, a_n) \) be the \( n \)-tuple of vectors where \( a_i = \nu(b_i) \). Also let \( M \) be the \( r \times n \) matrix whose columns are the vectors \( a_1, \ldots, a_n \). Using \( M \) we define a partial order in the group \( \mathbb{Z}^r \) as follows. Given \( \alpha, \beta \in \mathbb{Z}^n \) we say \( \alpha \succ_M \beta \) if \( M\alpha \succ M\beta \), where \( \succ \) in the righthand side is the total order on \( \mathbb{Z}^r \) used in the definition of the valuation \( \nu \). We note that since in general \( M \) is not a square matrix and hence not invertible, it can happen that \( \alpha \neq \beta \) but \( M\alpha = M\beta \). In this case, \( \alpha, \beta \) are incomparable in the partial order \( \succ_M \). We can define the notion of initial form of a polynomial with respect to \( \succ_M \). Let \( p(x) = \sum_{\alpha} c_\alpha x^\alpha \in k[x] \)
be a polynomial. Let \( m = \text{MIN}\{M\alpha \mid c_\alpha \neq 0\} \) where the minimum is with respect to the total order \( \succ \). We define the initial form \( \text{in}_M(p) \in k[x] \) by

\[
\text{in}_M(p)(x) = \sum_\beta c_\beta x^\beta,
\]

where the sum is over all the \( \beta \) with \( M \beta = m \). We let \( \text{in}_M(I) \) be the ideal of \( k[x] \) generated by \( \text{in}_M(p) \), \( \forall p \in I \). The initial form and the initial ideal are important constructions in Section 3. One makes the following observation:

**Lemma 2.15.** The ideal \( \text{in}_M(I) \) is contained in the ideal \( I_B \).

**Proof.** Let \( p(x) = \sum_\alpha c_\alpha x^\alpha \in I \), i.e. \( p(b_1, \ldots, b_n) = 0 \). Let \( \text{in}_M(p) \) be the initial form of \( p \) given by (2.2). We note that for any monomial \( c_\alpha x^\alpha \), its valuation \( v(c_\alpha x^\alpha) \) is given by

\[
v(c_\alpha b_1^{\alpha_1} \cdots b_n^{\alpha_n}) = M\alpha,
\]

where \( \alpha = (\alpha_1, \ldots, \alpha_n) \). From (2.3) and the non-Archimedean property of \( v \) (Definition 2.1(1)) we see that \( v(\text{in}_M(p)(b_1, \ldots, b_n)) \gg m \). Because otherwise, \( v(p(b_1, \ldots, b_n)) = m \) which contradicts the fact that \( p(b_1, \ldots, b_n) = 0 \). Thus, the image of \( \text{in}_M(p) \) in the quotient space \( F_{\gg m}/F_{> m} \) is 0, i.e. \( \text{in}_M(p) \in I_B \) as required.

The next theorem gives necessary and sufficient conditions for a set \( B \) of algebra generators to be a Khovanskii basis.

**Theorem 2.16.** Let \( B = \{b_1, \ldots, b_n\} \) be a set of algebra generators for \( A \). The following conditions are equivalent.

1. \( B \) is a Khovanskii basis.
2. The ideals \( \text{in}_M(I) \) and \( I_B \) coincide.
3. Let \( \{p_1, \ldots, p_s\} \) be generators for the ideal \( I_B \). Then, for \( i = 1, \ldots, s \), the subduction algorithm (Algorithm 2.11) applied to \( p_i(b_1, \ldots, b_n) \) terminates.

**Proof.** Recall that for any \( 0 \neq f \in A \) we let \( \bar{f} \) denote its image in \( \text{gr}_v(A) \). (1) \( \Rightarrow \) (2). Let \( p(x) = \sum_\alpha c_\alpha x^\alpha \in I_B \). Let \( m = \text{MIN}\{M\alpha \mid c_\alpha \neq 0\} \). Also let \( a = v(p(b_1, \ldots, b_n)) \). We know that \( p(b_1, \ldots, b_n) = 0 \). This implies that \( a \gg m \). Since \( B \) is assumed to be a Khovanskii basis, as in the proof of Lemma 2.10 we can find a polynomial \( p_1(x) = \sum_\beta c_\beta x^\beta \) such that \( p_1(b_1, \ldots, b_n) = p(b_1, \ldots, b_n) \) and moreover for every monomial \( c_\beta x^\beta \) appearing in \( p_1 \) we have \( M \beta = a \). Continuing with the subduction algorithm (Algorithm 2.11) we obtain a polynomial \( q(x) = p_1(x) + q_1(x) \) such that \( p_1(b_1, \ldots, b_n) = q_1(b_1, \ldots, b_n) \) and \( \text{in}_M(p) = \text{in}_M(q) \). It follows that \( p - q \in I \) and also \( \text{in}_M(p - q) = p \). This shows that \( p \in \text{in}_M(I) \) as required.

(2) \( \Rightarrow \) (1). Let \( A' \) denote the subalgebra of \( \text{gr}_v(A) \) generated by the \( b_i \). Suppose by contradiction that \( \text{in}_M(I) = I_B \) but \( B \) is not a Khovanskii basis. Then there exists \( p(x) = \sum_\alpha c_\alpha x^\alpha \in k[x] \) such that

\[
p(b_1, \ldots, b_n) \notin A'.
\]

Let \( m(p) = \text{MIN}\{M\alpha \mid c_\alpha \neq 0\} \). Note that \( m(p) \) is a nonnegative integer linear combination of the \( v(b_i) \) and hence \( m(p) \in S' \) where \( S' \) is the semigroup generated by the \( v(b_i) \). By assumption, the value semigroup \( S \), and hence its subsemigroup \( S' \), are maximum well-ordered. Thus, without loss of generality, we can assume that \( m(p) \) is maximum among all the polynomials satisfying (2.4). For (2.4) to hold, we must have \( v(\text{in}_M(p)(b_1, \ldots, b_n)) \gg m(p) \) which shows that \( p \in I_B \). From the equality of \( I_B \) and \( \text{in}_M(I) \) we then conclude that there exists \( q \in I \) such that \( \text{in}_M(q) = \text{in}_M(p) \). Since \( q \in I \) we see that \( (p - q)(b_1, \ldots, b_n) = p(b_1, \ldots, b_n) \) and hence \( (p - q)(b_1, \ldots, b_n) = p(b_1, \ldots, b_n) \notin A' \). On the other hand, \( \text{in}_M(q) = \text{in}_M(p) \)
implies that \( m(p - q) > m(p) \). This contradicts that \( m(p) \) was maximum among the polynomials satisfying (2.4). This finishes the proof.

(1) \( \Rightarrow \) (3) is obvious, we only need to prove (3) \( \Rightarrow \) (1). Let \( 1 \leq i \leq n \). Then by assumption, the subduction algorithm (Algorithm 2.11) produces a polynomial \( q_i(x) = \sum_{j=1}^{s_i} c_{ij} x^{\alpha_{ij}} \) such that \( p_i(b_1, \ldots, b_n) = q_i(b_1, \ldots, b_n) \) and

\[
v(\text{in}_M(p)(b_1, \ldots, b_n)) = M\alpha_{i1} \succ M\alpha_{i2} \succ \cdots \succ M\alpha_{in}.
\]

Thus, \( p_i = \text{in}_M(p_i - q_i) \in \text{in}_M(I) \). It follows that \( I_B \subseteq \text{in}_M(I) \). Finally, from Lemma 2.15 and (2) above we conclude that \( B \) is a Khovanskii basis.

We can now present an algorithm to find a finite Khovanskii basis starting from a set of algebra generators, provided that such a basis exists.

**Algorithm 2.17** (Finding a finite Khovanskii basis). **Input:** A finite set of \( k \)-algebra generators \( \{b_1, \ldots, b_n\} \) for \( A \). **Output:** A finite Khovanskii basis \( B \).

1. Put \( B = \{b_1, \ldots, b_n\} \). Let \( \mathcal{B} \) be the image of \( B \) in \( \text{gr}_v(A) \).
2. Let \( I_B \) be the ideal in \( \text{gr}_v(A) \) which is the kernel of the homomorphism \( k[x_1, \ldots, x_n] \to \text{gr}_v(A) \). Let \( G \) be a finite set of generators for \( I_B \).
3. Take an element \( g \in G \). Let \( h \in A \) be the element obtained by plugging \( b_i \) for \( x_i \) in \( g \), \( i = 1, \ldots, n \). Let \( \bar{h} \) denote the image of \( h \) in \( \text{gr}_v(A) \).
4. If this is the case, find a polynomial \( p(x_1, \ldots, x_n) \) such that \( \bar{h} = p(\bar{b}_1, \ldots, \bar{b}_n) \).

This means that either \( h = p(b_1, \ldots, b_n) \) or \( v(h - p(b_1, \ldots, b_n)) > v(h) \). Put \( h_1 = h - p(b_1, \ldots, b_n) \). If \( h_1 = 0 \) go to the step (6). Otherwise, replace \( h \) with \( h_1 \) and go to the step (3).
5. If \( \bar{h} \) does not lie in the subalgebra generated by \( \mathcal{B} \) then add \( h \) to \( \mathcal{B} \). Go to the step (1).
6. Repeat until there are no generators left in \( G \). The set \( B \) is our desired finite Khovanskii basis.

**Corollary 2.18.** Algorithm 2.17 terminates in a finite number of steps if and only \((A, v)\) has a finite Khovanskii basis.

**Proof.** Follows from Theorem 2.16. \( \square \)

2.3. **Background on Newton-Okounkov bodies.** Finally we briefly discuss the definition and main properties of of a Newton-Okounkov body associated to a positively graded algebra \( A \). It is a convex body which encodes information about the asymptotic behavior of Hilbert function of \( A \). It is a far generalization of the Newton polytope of a projective toric variety. Our presentation here is close to the approach in [KK12].

We begin with the definition of a Newton-Okounkov cone.

**Definition 2.19** (Newton-Okounkov cone). Let \( A \) be a (not necessarily graded) domain. Let \( v : A \setminus \{0\} \to \mathbb{Z}^r \) be a valuation. We define the Newton-Okounkov cone \( P(A, v) \) to be the closure of the convex hull of \( S \cup \{0\} \), where \( S = S(A, v) \) is the value semigroup.

We note that if \( S \) is a finitely generated semigroup then the cone \( P(A, v) \) is a rational polyhedral cone, but the converse is not true.

Now we follow [KK12] Section 2.3 and take \( A = \bigoplus_{i \geq 0} A_i \) to be a positively graded algebra. Without loss of generality we can assume that \( A \) is embedded, as a graded \( k \)-algebra, into a polynomial ring \( F[t] \) (in one indeterminate \( t \)) where \( F \) is a field containing \( k \). For example one can take \( F \) to be the degree 0 part of the quotient field of \( A \). Let
\(\nu' : F \setminus \{0\} \to \mathbb{Z}'\) be a valuation. We can extend \(\nu'\) to a valuation \(\nu : A \setminus \{0\} \to \mathbb{N} \times \mathbb{Z}'\) which refines the grading by degree as follows. Firstly, equip \(\mathbb{Z}^{r+1}\) with the following group ordering: for \((m, a), (n, b) \in \mathbb{Z} \times \mathbb{Z}'\), let us say that \((m, a) \succ (n, b)\) if either \(m < n\), or \(m = n\) and \(a \succ b\). Now let \(f \in A\) be an element of degree \(m\) and write \(f = \sum_{i=0}^{m} f_i\), as sum of its homogeneous components. We put \(\nu(f) = (m, \nu'(f_m))\). One verifies that \(\nu\) is a valuation. Moreover, if \(\nu'\) has one-dimensional leaves then \(\nu\) also has one-dimensional leaves.

**Definition 2.20** (Newton-Okounkov body). Let \((A, \nu)\) be as above. The *Newton-Okounkov body* \(\Delta(A, \nu)\) is defined to be the intersection of the Newton-Okounkov cone \(P(A, \nu)\) with the plane \(\{1\} \times \mathbb{R}'\). Alternatively, \(\Delta(A, \nu)\) can be defined as:

\[
\Delta(A, \nu) = \text{conv}(\bigcup_{i>0} \{\nu'(f)/i \mid 0 \neq f \in A_i\}) \subset \mathbb{R}'.
\]

**Remark 2.21.** Note that in the definition we do not require that \(A\) is a finitely generated algebra. Without any assumption on \(A\) the corresponding set \(\Delta(A, \nu)\) may be unbounded and not interesting. One shows that if \(A\) is contained in a finitely generated graded algebra (in particular if \(A\) itself is finitely generated) then the corresponding \(\Delta(A, \nu)\) is bounded and hence is a convex body.

The following is the main result about the Newton-Okounkov bodies of graded algebras. Let \(A\) be a positively graded algebra. As above equip \(A\) with a valuation \(\nu : A \setminus \{0\} \to \mathbb{N} \times \mathbb{Z}'\). Recall that the Hilbert function of \(A\) is the function \(H_A : \mathbb{N} \to \mathbb{N}\) defined by \(H_A(i) = \dim_k(A_i)\) for all \(i\).

**Theorem 2.22.** Let us assume that \(A\) is contained in a finitely generated algebra. Also assume that the valuation \(\nu\) has one-dimensional leaves. We then have

\[
\lim_{i \to \infty} \frac{H_A(i)}{k^i} = \text{vol}_q(\Delta(A, \nu)),
\]

where \(q\) is the dimension of the Newton-Okounkov body \(\Delta(A, \nu)\) and \(\text{vol}\) denotes the (appropriately normalized) \(q\)-dimensional volume in the affine span of \(\Delta(A, \nu)\).

**Corollary 2.23.** Let \(Y\) be a projective variety of dimension \(d\) sitting in a projective space \(\mathbb{P}^N\). Let \(A\) be the homogeneous coordinate ring of \(Y\). Equip \(A\) with a valuation \(\nu\) with one-dimensional leaves as above. Then the degree of \(Y\) is equal to \(d!\) times the volume of the convex body \(\Delta(A, \nu)\) \(\subset \mathbb{R}^d\).

**Remark 2.24.** As above, let \(A\) be positively graded and equipped with a valuation \(\nu\) with one-dimensional leaves. When \((A, \nu)\) has a finite Khovanskii basis, the corresponding Newton-Okounkov body \(\Delta(A, \nu)\) is a rational polytope and we have a toric degeneration of \(Y = \text{Proj}(A)\) to a (not-necessarily normal) toric variety whose normalization is the toric variety associated to \(\Delta(A, \nu)\) ([And13, Kav15] Section 7) and [Tei03]).

2.4. Quasivaluations and filtrations. It is conceptually useful to relax the valuation axioms and consider the so-called quasivaluations. A quasivalence differs from a valuation only in that it is only superadditive with respect to multiplication.

**Definition 2.25.** Let \((\Gamma, \succ)\) be a linearly ordered Abelian group and let \(A\) be a \(k\)-algebra. A function \(\nu : A \setminus \{0\} \to \Gamma\) is said to be a *quasivalence* over \(k\) if the following properties hold:

1. For all \(0 \neq f, g \in A\) we have \(\nu(f + g) \geq \text{MIN}\{\nu(f), \nu(g)\}\).
2. For all \(0 \neq f, g \in A\) we have \(\nu(fg) \geq \nu(f) + \nu(g)\).
(3) For all $0 \neq f \in A$ and $0 \neq c \in k$ we have $v(cf) = v(f)$.

It is sometimes useful to define a quasivaluation to be a map $v : A \to \Gamma \cup \{\infty\}$ satisfying the above axioms, where $\infty$ is greater than all elements in $\Gamma$.

For the cases we consider $\Gamma$ will be $\mathbb{Q}^r$ with a linear ordering and $v$ will be assumed to be discrete, i.e. its image is a discrete subset of $\mathbb{Q}^r$. Similar to valuations, a quasivaluation $v$ defines a corresponding filtration $F_v = \{F_{v \geq a} \mid a \in \mathbb{Q}^r\}$ on $A$. A quasivaluation with one-dimensional leaves is defined as before, namely we require that for each $a \in \mathbb{Q}^r$ the quotient space $F_{v \geq a}/F_{v > a}$ is at most 1-dimensional (see Definition 2.1(4)).

Conversely, given a decreasing algebra filtration $F = \{F_a\}_{a \in \mathbb{Q}^r}$ of $A$ by $k$-vector subspaces, the function $v_F$ below is a quasivaluation. For any $0 \neq f \in A$ define:

$$v_F(f) = \text{MAX}\{a \in \mathbb{Q}^r \mid f \in F_a\}.$$  

If the maximum is not attained we define $v_F(f)$ to be infinity. Nevertheless, we are only interested in cases where the maximum is always attained. The two constructions of $F_v$ and $v_F$ are inverse to each other when $v$ is discrete. For any filtration $F = \{F_a\}_{a \in \mathbb{Q}^r}$, one defines the associated graded algebra $\text{gr}_F(A)$ by

$$\text{gr}_F(A) = \bigoplus_{a \in \mathbb{Q}^r} F_a/F_{a'},$$

where $F_{a'} = \bigcup_{a' > a} F_{a'}$. When $F = F_v$ for some quasivaluation $v$ we write $\text{gr}_v(A)$ instead of $\text{gr}_F(A)$. A discrete quasivaluation $v$ is a valuation if and only if $\text{gr}_v(A)$ is a domain.

A special case of the construction $v_F$ is the valuation associated to a grading in Example 2.2(1).

2.5. Adapted bases. It would be natural and important for us to also consider the notion of a vector space basis which behaves well with respect to a given valuation (or more generally a quasivaluation). This is what we call an adapted basis. We point out that while Khovanskii bases are generators of an algebra $A$, adapted bases are vector space bases.

**Definition 2.26.** A $k$-vector space basis $B \subset A$ is said to be adapted to a filtration $F = \{F_a\}_{a \in \mathbb{Q}^r}$ if $F_a \cap B$ is a vector space basis for $F_a$, for all $a$. Similarly $B$ is said to be adapted to a quasivaluation $v$ if it is adapted to its associated filtration $F_v$.

We would like to point out that when $v$ has an adapted basis then the maximum in (2.5) is always attained.

**Example 2.27.** As in Example 2.2(1) let $A = \bigoplus_{g \in \Gamma} A_g$ be a $\Gamma$-grading of an algebra $A$ where $\Gamma$ is an ordered group. For each $g \in \Gamma$ let $B_g$ be a $k$-vector space basis for $A_g$ and let $B = \bigcup_{g \in \Gamma} B_g$. It is straightforward to see that $B$ is adapted to the valuation $v$ associated to the $\Gamma$-grading. An important special case of this is considered in Section 4.1 where the set of monomials is an adapted basis for a polynomial algebra $k[x]$ with respect to any weight valuation.

**Example 2.28.** Let $G$ be a connected reductive group over an algebraically closed field $k$, and let $U \subset G$ be a maximal unipotent subgroup. As a $G$-module, the coordinate ring $k[G/U]$ of the variety $G/U$ is known to decompose into a direct sum $\bigoplus_{\lambda \in \Lambda_+} V(\lambda)$ over all irreducible representations of $G$. Each of these representations has a distinguished (dual)
canononical basis \( \mathcal{B}(\lambda) \subset V(\lambda) \) constructed by Lusztig ([Lus90]). The set \( \mathcal{B} = \bigsqcup_{\lambda \in \Lambda_+} \mathcal{B}(\lambda) \) is the dual canonical basis of \( k[G/U] \).

For each reduced decomposition \( w_0 \) of the longest word \( w_0 \) of the Weyl group of \( G \) there is a valuation \( v_{w_0} \) on the coordinate ring of \( G/U \) which has one-dimensional leaves and is adapted to \( \mathcal{B} \) (see [Kav15, Man16]). These are known as string valuations; they provide a method to construct toric degenerations of \( G/U \) as well as any flag variety of \( G \) ([Cal02, AB04, Kav15]).

Other variants of adapted bases in representation theory are studied in greater generality by Feigin, Fourier, and Littelmann in [FFL], where they are called essential bases.

**Remark 2.29.** It immediately follows from the definition that the set of values of \( v \) on \( A \) coincides with the set of values of \( v \) on any adapted basis \( \mathcal{B} \). Moreover, if \( v \) has one-dimensional leaves then a subset \( \mathcal{B} \) is an adapted basis if and only if \( b \mapsto v(b) \) gives a bijection between \( \mathcal{B} \) and the set of values of \( v \).

We can formulate a vector space version of the subduction algorithm (Algorithm 2.11). Let \( \overline{\mathcal{B}} \subset \text{gr}_v(A) \) be a vector space basis consisting of homogeneous elements. Also let \( \mathcal{B} \subset A \) be a lift of \( \overline{\mathcal{B}} \) to \( A \), i.e. for each \( b \in \overline{\mathcal{B}} \), we have a unique \( b \in \mathcal{B} \) whose image is \( \overline{b} \).

**Algorithm 2.30** (Vector space subduction). **Input:** A vector space basis \( \overline{\mathcal{B}} \subset \text{gr}_v(A) \), a lift \( \mathcal{B} \subset A \) of \( \overline{\mathcal{B}} \) to \( A \) and an element \( f \in A \). **Output:** An expression of \( f \) as a linear combination of the elements in \( \mathcal{B} \).

1. Compute \( v(f) = a \) and take the equivalence class \( \overline{f} \in F_{v>a}/F_{v\geq a} \).
2. Express \( \overline{f} \) as a linear combination of elements in \( \overline{\mathcal{B}} \), that is, \( \overline{f} = \sum_i c_i \overline{b_i} \).
3. If \( f = \sum_i c_i b_i \) we are done. Otherwise replace \( f \) with \( f - \sum_i c_i b_i \in F_{v>a} \) and go to (1).

We have the following lemma. We omit the straightforward proof.

**Lemma 2.31.** A lift \( \mathcal{B} \subset A \) of a basis \( \overline{\mathcal{B}} \subset \text{gr}_v(A) \) is a vector space basis for \( A \) (and hence a basis adapted to \( v \)) if and only if Algorithm 2.30 always terminates after a finite number of steps. In this case, we have the following: for any \( 0 \neq f \in A \) write \( f = \sum c_i b_i \) as a linear combination of the basis elements \( b_i \in \mathcal{B} \). Then \( v(f) = \text{MIN}\{v(b_i) \mid c_i \neq 0\} \).

Many different bases of \( A \) can be adapted to the same quasivaluation \( v \). Any two such bases are related by a lower triangular change of coordinates.

**Proposition 2.32.** Let \( v \) be a quasivaluation with one-dimensional leaves. Let \( \mathcal{B}, \mathcal{B}' \subset A \) be adapted to \( v \). Then any \( b \in \mathcal{B} \) has a lower-triangular expression in the basis \( \mathcal{B}' \), and vice versa:

\[
\begin{align*}
b &= cb' + \sum_{v(b_i') > v(b)} c_i b_i', \\
v(b) &= v(b'),
\end{align*}
\]

with \( c \) and the \( c_i \in k \) and \( c \neq 0 \).

**Proof.** This follows from Lemma 2.31.

3. **Gröbner bases and higher rank tropical geometry**

In this section we introduce what we will need from the theory of Gröbner bases and tropical geometry. We extend the theory of monomial weightings to weightings by ordered groups of rank greater than 1 (in particular \( \mathbb{Q}^r \), for \( r \geq 1 \), and equipped with a group ordering). This lays the groundwork for studying higher rank valuations and quasivaluations from an algorithmic perspective (see Section 4). One important lemma that we will need
later in Section 3 is Lemma 3.3 which relates the initial ideal with respect to a higher rank weighting and usual rank 1 weightings.

**Remark 3.1.** Higher rank versions of tropicalization have been studied by Foster and Ranaganathan (PR16).

### 3.1. Gröbner theory

We refer the reader to [Stu96], [Eis95], and [CLO15] for the basics of the theory of Gröbner bases. We will consider weightings of the monomials in a polynomial ring \( k[x] = k[x_1, \ldots, x_n] \) by elements of \((\mathbb{Q}^r, >)\), where \( > \) is a group ordering. Although the geometric aspects of the term orders resulting from these weightings differ from those of weightings by \( \mathbb{Q} \) (for example, we avoid discussion of the meaning of the Gröbner fan when \( r > 1 \)), many of the algebraic and algorithmic properties of these term orders continue to hold. We use the MIN convention throughout the paper.

Recall that a monomial ordering \( > \) is a total ordering on the set of monomials in \( k[x] \) which respects multiplication and moreover is maximum well-ordered. Given a polynomial \( f(x) = \sum_{\alpha} c_{\alpha} x^\alpha \in k[x] \), the initial monomial in \( f \) with respect to a monomial ordering \( > \) is the least monomial \( c_\beta x^\beta \) where \( \beta = \min\{\alpha \mid c_\alpha \neq 0\} \) and the minimum is taken with respect to \( > \).

We also recall the notion of higher rank monomial weighting from Section 2.2 (see (2.2)). Consider \( \mathbb{Q}^r, r \geq 1 \), equipped with a group ordering \( > \). Let \( M \in \mathbb{Q}^{r \times n} \) be an \((r \times n)\)-matrix which we regard as a rank \( r \) weighting of the indeterminates \( x = (x_1, \ldots, x_n) \). That is, for each \( i \), the weight of \( x_i \) is the \( i \)-th column vector of \( M \). Let \( f(x) = \sum_{\alpha} c_{\alpha} x^\alpha \in k[x] \) be a polynomial. The initial form of \( f \) with respect to the weighting \( M \) is defined as \( \text{in}_M(f) = \sum_{\alpha} c_{\alpha} x^\alpha \) where the sum is over all the \( \gamma \) where the minimum \( \min\{M\alpha \mid c_\alpha \neq 0\} \) is attained. Here \( \alpha \) is regarded as a column vector and the minimum is with respect to the ordering \( > \) on \( \mathbb{Q}^r \).

The initial ideal \( \text{in}_M(I) \) for \( M \in \mathbb{Q}^{r \times n} \) is the ideal generated by \( \text{in}_M(f) \), \( \forall f \in I \). Each \( M \) defines a \( \mathbb{Q}^r \)-grading on \( k[x] \), and \( \text{in}_M(I) \) is a homogeneous ideal with respect to this grading. In particular, \( \text{in}_M(I) \) is generated by \( M \)-homogeneous forms.

**Definition 3.2** (Gröbner region). We define the higher rank Gröbner region \( \text{GR}^r(I) \subset \mathbb{Q}^{r \times n} \) of an ideal \( I \subset k[x] \) as follows.

1. We say that \( M \in \mathbb{Q}^{r \times n} \) is in the **Gröbner region** \( \text{GR}^r(I) \) if and only if there is some monomial ordering \( > \) such that the following holds:

\[
\text{in}_>(\text{in}_M(I)) = \text{in}_>(I).
\]

For a fixed monomial ordering \( > \), we denote the set of \( M \) satisfying (3.1) by \( C_r^>(I) \).

2. We also define the set \( C_M(I) \subset \mathbb{Q}^{r \times n} \) as the collection of those \( M \in \mathbb{Q}^{r \times n} \) such that \( \text{in}_M'(I) = \text{in}_M(I) \).

The monomials not contained in \( \text{in}_>(I) \) are usually called **standard monomials**. It is well-known that the images of standard monomials in \( k[x]/I \) are a vector space basis for this quotient which we denote by \( \mathbb{B}_>(I) \) (or simply by \( \mathbb{B} \) when there is no chance of confusion).

We will need the following lemma. Its proof is exactly as the proof of [Jen07] Lemma 3.1.11.

**Lemma 3.3.** Any \( h \in \text{in}_M(I) \) can be written as a sum \( \sum_i \text{in}_M(f_i) \) for \( f_i \in I \), where the summands all have different homogeneous \( M \)-degrees.

Also let \( G_r^>(I) \) denote the reduced Gröbner basis of \( I \) with respect to \( > \). As with the standard Gröbner theory, it is possible to check for membership in \( C_r^>(I) \) using \( G_r^>(I) \). This is the content of the next lemma.
Lemma 3.4. A weight $M \in \mathbb{Q}^r \times \mathbb{N}^n$ is in $C^>_{M}(I)$ if and only if $\text{in}_{>}(\text{in}_{M}(g)) = \text{in}_{>}(g)$ for all $g \in G_{>}(I)$. In particular, $C^>_{M}(I)$ is defined by a finite set of inequalities.

Proof. This is similar to the $r = 1$ case and we will just sketch the proof. Suppose that $M \in C^>_{M}(I)$, then $\text{in}_{>}(\text{in}_{M}(g)) \in \text{in}_{>}(I)$ for all $g \in G_{>}(I)$. As $\text{in}_{>}(\text{in}_{M}(g))$ is a monomial and $G_{>}(I)$ is reduced, we must have that $\text{in}_{>}(\text{in}_{M}(g)) = \text{in}_{>}(g)$. Now suppose that $\text{in}_{>}(\text{in}_{M}(g)) = \text{in}_{>}(g)$ for all $g \in G_{>}(I)$, then we immediately have that $\text{in}_{>}(I) \subseteq \text{in}_{>}(\text{in}_{M}(I))$. The proof of the other inclusion is as in [Jen07, Lemma 3.1.12]. □

We can find the reduced Gröbner basis for $\text{in}_{M}(I)$ from that of $I$.

Lemma 3.5. Let $M \in C^>_{M}(I)$. Then

$$G_{>}(\text{in}_{M}(I)) = \{\text{in}_{M}(g) \mid g \in G_{>}(I)\}.$$ (3.2)

is the reduced Gröbner basis for $\text{in}_{M}(I)$ with respect to $>$. Proof. We know that $\text{in}_{>}(\text{in}_{M}(I)) = \text{in}_{>}(I)$ is generated by the $\text{in}_{>}(g)$ with $g \in G_{>}(I)$, and by Lemma 3.4, (3.2) is well-known that the negative orthant is always part of the Gröbner region when $r > 1$. The next lemma gives a characterization of the set $C^>_{M}(I)$ for when $M$ lies in the Gröbner region $\text{GR}^r(I)$. The proof is exactly as in the proof of [Jen07, Proposition 3.1.4].

Lemma 3.6. Let $M \in C^>_{M}(I)$, then $M' \in C_M(I)$ if and only if $\text{in}_{M}(g) = \text{in}_{M'}(g)$ for all $g \in G_{>}(I)$.

The Gröbner region $\text{GR}^r(I) \subset \mathbb{Q}^r \times \mathbb{N}^n$ for $r > 1$ behaves much like the $r = 1$ case. It is well-known that the negative orthant is always part of the Gröbner region when $r = 1$ (recall that we are using the MIN convention). The following is a generalization of this fact to $r \geq 1$.

Recall from Section 2.1 that by the Hahn embedding theorem there is always an embedding of ordered groups $\eta : \mathbb{Q}^r \to \mathbb{R}^r$, where $\mathbb{R}^r$ is given the standard lexicographic ordering. In particular, the subset $\mathbb{Q}^- = \eta^{-1}(\mathbb{Q}^\times \cap (\mathbb{R}_{\geq 0})^r)$ has the property that for any lattice $L \subset \mathbb{Q}^r$, the set $L \cap \mathbb{Q}^-$ is maximum well-ordered. Furthermore, there is always an element $1 \in \mathbb{Q}^-$ such that for any $w \in \mathbb{Q}^r$, we have $w + N1 \in \mathbb{Q}^-$ for $N$ sufficiently large. If $\succ$ is taken to be the standard lexicographic ordering, then $Q^- = (\mathbb{Q}_{\leq 0})^r$ and $1 = (-1, \ldots, -1) \in \mathbb{Q}^r$.

Lemma 3.7. For any $I \subset \mathbb{k}[x]$ we have $\mathbb{Q}^{-} I \subset \text{GR}(I)$. Furthermore, if $I$ is homogeneous with respect to a positive grading then $\text{GR}^r(I) = \mathbb{Q}^r \times \mathbb{N}^n$.

Proof. If $M \in (\mathbb{Q}^-)^n$ then for any monomial $x^\alpha$ there are only finitely many monomials $x^\beta$ with $M\beta \succ M\alpha$. It follows that if $>$ is any monomial ordering, then the composite ordering $>_{M}$ defined by

$$x^\beta >_{M} x^\alpha \Leftrightarrow M\beta \succ M\alpha \text{ or } M\beta = M\alpha \text{ and } x^\beta > x^\alpha,$$

(3.3)

is also a monomial ordering. By definition $\text{in}_{>_{M}}(\text{in}_{M}(I)) = \text{in}_{>_{M}}(I)$ which shows that $M \in \text{GR}^r(I)$. The second part follows from the following fact: Let $I$ be homogeneous with respect to $(d_1, \ldots, d_n) \in \mathbb{Q}^n$, where $d_i$ is the degree of $x_i$, and let $D \in (\mathbb{Q}^-)^n$ be the matrix whose columns are $d_11, \ldots, d_n1$. Then any multiple of $D$ can be added to $M$ without altering the initial ideal. □

In the $r = 1$ case it is well known that the $C^>_{M}(I)$ are polyhedral cones, and that they are the closures of the maximal faces of the Gröbner fan $\Sigma(I)$. 21
3.2. Comparison of initial ideals. Initial ideals with respect to weightings $M \in \mathbb{Q}^{r \times n}$ are related to initial ideals from the $r = 1$ case by the following lemma. This statement will be important for us in Section [5]. Let $\mathbb{Q}$ be equipped with the standard lexicographic ordering $\succ$.

**Lemma 3.8.** Let $M \in \mathbb{Q}^{r \times n}$ and let $u_1, \ldots, u_r$ be the rows of the matrix $M$. Then the following initial ideals coincide:

$$(3.4) \quad \text{in}_M(I) = \text{in}_{u_r}(... \text{in}_{u_1}(I) ...).$$

**Proof.** First observe that for any $f \in I$ we have $\text{in}_M(f) = \text{in}_{u_r}(... \text{in}_{u_1}(f) ...)$, which implies that $\text{in}_M(I) \subset \text{in}_{u_r}(... \text{in}_{u_1}(I) ...)$. By induction on $r$, let $h \in \text{in}_{u_r}(... \text{in}_{u_1}(I) ...)$, where $M' \in \mathbb{Q}^{(r-1) \times n}$ is the matrix with rows $u_1, \ldots, u_{r-1}$, regarded as a $\mathbb{Q}^{r-1}$-monomial weighting. We use Lemma [3.3] to write $h = \sum \text{in}_{u_r}(f_i)$ where $f_i \in \text{in}_{M'}(I)$ and each $\text{in}_{u_r}(f_i)$ has a distinct homogeneous $u_r$-degree. This implies that no monomials are shared among the $\text{in}_{u_r}(f_i)$. Another application of Lemma [3.3] implies that each $f_i$ can be written as $\sum_{j} \text{in}_{M'}(g_{ij})$ for $g_{ij} \in I$, where each $\text{in}_{M'}(g_{ij})$ has a distinct homogeneous $M'$-degree. For each $i$, the $\text{in}_{M'}(g_{ij})$ likewise share no monomials. It follows that $\text{in}_{u_r}(f_i) = \sum_{j} \text{in}_{u_r}(\text{in}_{M'}(g_{ij}))$ and hence $h = \sum_{i,j} \text{in}_{u_r}(\text{in}_{M'}(g_{ij}))$. \square

For any $u \in \mathbb{Q}^n$ we can find $M \in \mathbb{Q}^{r \times n}$ such that $\text{in}_u(I) = \text{in}_M(I)$, for example, we can define $M$ to be the $r \times n$ matrix all of whose rows are equal to $u$. Now we show that it is possible to always possible to produce the initial ideal for some $M \in \mathbb{Q}^{r \times n}$ as the initial ideal of some $u \in \mathbb{Q}^n$.

Let $A_i = \{\alpha_{i1}, \ldots, \alpha_{in}\} \subset \mathbb{Q}^r$, $1 \leq i \leq m$, be finite sets (later we will take $A_i$ to be the set of $M$-weights of monomials in some polynomial $f_i$ for some weighting matrix $M \in \mathbb{Q}^{r \times n}$). We denote the smallest element in each $A_i$ by $\beta_i$. Also, for $u, v \in \mathbb{Q}^r$, we write $u \cdot v$ for the standard inner product of these vectors.

**Lemma 3.9.** There is a vector $v \in \mathbb{Q}^r_{\geq 0}$ such that $v \cdot (\beta_i - \alpha_{ij}) < 0$ whenever $\alpha_{ij} \succ \beta_i$.

**Proof.** We follow the proof of [Stu96, Proposition 1.11]. By the Farkas lemma, if no such $v$ existed, we could find $\lambda_{ij} \in \mathbb{Z}_{\geq 0}$ such that all the components of the vector $\sum_{i,j} \lambda_{ij} (\beta_i - \alpha_{ij})$ are nonnegative. As $\succ$ is a group ordering, this implies that $\sum_{i,j} \lambda_{ij} \beta_i \geq \sum_{i,j} \lambda_{ij} \alpha_{ij}$. But, for each $i$, $\beta_i$ is the minimum of the $\alpha_{ij}$ and thus $\sum_{i,j} \lambda_{ij} \beta_i \geq \sum_{i,j} \lambda_{ij} \alpha_{ij}$. \square

Given a finite number of polynomials, Lemma [3.9] shows that for every $M \in \mathbb{Q}^{r \times n}$ there exists $u \in \mathbb{Q}^n$ such that the initial forms of these polynomials with respect to $M$ are the same as their initial forms with respect to $u$. This gives us the following.

**Proposition 3.10.** Let $I \subset k[x]$ be an ideal, then for any $M \in \mathbb{Q}^{r \times n}$ there is some $u \in \mathbb{Q}^n$ such that $\text{in}_M(I) = \text{in}_u(I)$.

**Proof.** First we assume that $I$ is homogeneous with respect to a positive grading on $k[x]$. This implies that $M \in C^r_{>0}(I) \subset \text{GR}^r(I)$ for some monomial ordering $\succ$. Let $G_{>0}(I) \subset I$ be the associated reduced Gröbner basis. The weighting $M$ assigns an element $\alpha_{ij} \in \mathbb{Q}^r$ to each monomial of $g_i \in G_{>0}(I)$. By Lemma [3.9] we can find $v \in \mathbb{Q}^r_{\geq 0}$ such that if $u \in \mathbb{Q}^r$ is the vector whose $i$-th component is the dot product of $v$ with the $i$-th column of $M$ then we have $\text{in}_M(g_i) = \text{in}_u(g_i)$ for all $g_i \in G_{>0}(I)$. This in turn imply that $\text{in}_u(I) = \text{in}_M(I)$. Next, we let $I$ be a general ideal, i.e. not necessarily homogeneous. We then form the homogenization $I_h \subset k[x_0, x]$ (see [MS13, Chapter 2]). Let $(0, M) \in \mathbb{Q}^{r \times (n+1)}$ be the matrix obtained from
\( M \) by adding a 0 column to the left. The proof of \([\text{MS15, Proposition 2.6.1}]\) shows that for any \( M \in \mathbb{Q}^{r \times n} \) we have \( \text{in}_{(0, M)}(I_h)_{x_0=1} = \text{in}_M(I) \), where \( \text{in}_{(0, M)}(I_h)_{x_0=1} \subset k[x] \) is the ideal obtained by setting \( x_0 \) equal to 1. Since \( x_0 \) is weighted 0, an application of Lemma \([3.9] \) to an appropriate Gröbner basis of \( I_h \) produces a vector \((0, u) \in \mathbb{Q}^{n+1} \). Now we observe that
\[
\text{in}_M(I) = \text{in}_{(0, M)}(I_h)_{x_0=1} = \text{in}_{(0, u)}(I_h)_{x_0=1} = \text{in}_u(I),
\]
as required. \( \square \)

It is easy to find a weighting \( u \in \mathbb{Q}^n \) as in Proposition \([3.10] \) if the rows of the weighting matrix \( M \) are taken from the same cone in the Gröbner fan \( \Sigma(I_h) \) (or \( \Sigma(I) \) if \( I \) is itself homogeneous with respect to a positive grading).

**Proposition 3.11.** Suppose that the rows of the weighting matrix \( M \) are taken from the same cone in the Gröbner fan \( \Sigma(I_h) \). Then \( \text{in}_M(I) = \text{in}_u(I) \) for \( u = \sum_i u_i \).

**Proof.** From Lemma \([3.8] \) and \([\text{Stu96, Proposition 1.13}] \), we can conclude that if \( N \) is sufficiently large we have \( \text{in}_{(0, M)}(I_h) = \text{in}_{(0, \sum_i u_i)}(I_h) \). This finishes the proof. \( \square \)

Finally we end the section with the definition of lineality space of an ideal.

**Definition 3.12** (Lineality space). The lineality space \( L(I) \) of an ideal \( I \subset k[x] \) is the set of all \( u \in \mathbb{Q}^n \) with respect to which \( I \) is homogeneous. In other words, \( u \in L(I) \) if and only if \( \text{in}_u(I) = I \). Similarly, if we consider \( \mathbb{Q}^r \) equipped with a group ordering \( \succ \), then the lineality space \( L^r(I) \) is the set of all weighting matrices \( M \in \mathbb{Q}^{r \times n} \) such that \( \text{in}_M(I) = I \).

One observes that \( \text{in}_M(I) \) is homogeneous with respect to the \( \mathbb{Q}^r \)-grading on \( k[x] \) defined by any \( M' \in C_M(I) \).

### 3.3. Tropical Geometry

We briefly recall the notion of tropical variety of an ideal. We also give an extension of it to higher ranks. We suggest the book by Maclagan and Sturmfels \([\text{MS15}] \) for an excellent introduction to tropical geometry. We will confine ourselves to tropicalization over a trivially valued field \( k \).

**Definition 3.13.** Let \( I \subset k[x] \) be an ideal. The tropical variety \( T(I) \subset \mathbb{Q}^n \) is the set of \( u \in \mathbb{Q}^n \) such that \( \text{in}_u(I) \) contains no monomials.

The tropical variety carries the structure of a weighted polyhedral fan \([\text{MS15}] \). Furthermore, if \( I \) is homogeneous with respect to some positive grading on \( k[x] \), it can be considered to be a subfan of the Gröbner fan \( \Sigma(I) \) \([\text{SS14}] \). More generally, if \( I \) is not homogeneous, or is an ideal in a Laarnt polynomial ring, the tropical variety can be studied through its relationship with the homogenization \( I_h \). In particular, the tropical variety \( T(I) \) can be taken to be a union of faces of the Gröbner fan of \( I_h \) intersected with the hyperplane defined by setting the \( x_0 \)-weight equal to 0 \([\text{MS15, Proposition 2.6.2}] \). A consequence of this construction is that there is a subdivision of \( T(I) \) into open polyhedral cones \( C \) such that if \( u, u' \) are in the same cone, then \( \text{in}_u(I) = \text{in}_{u'}(I) \) \([\text{MS15, proof of Theorem 2.6.5}] \).

The following is clear from the definition of \( T(I) \).

**Lemma 3.14.** If \( \text{in}_u(I) \) is prime and \( \{x_1, \ldots, x_n\} \cap \text{in}_u(I) = \emptyset \) then \( u \in T(I) \).

The initial ideals \( \text{in}_u(I) \) for \( u \in T(I) \) share some of the properties of \( I \). For example, for an arbitrary \( u \in \mathbb{Q}^n \), the initial ideal \( \text{in}_u(I) \) could be all of \( k[x] \), however if \( u \in T(I) \) then the dimension of \( k[x]/\text{in}_u(I) \) is equal to that of \( k[x]/I \) \([\text{Jen07, Theorem 8.2.1}] \).

It is not immediately clear what “geometry” means when we make tropical constructions over more general ordered groups, but the relevant definitions on ideals still make sense. For example we make the following definition.
Definition 3.15. Let $I \subset k[x]$ be an ideal. Consider $\mathbb{Q}^r$ equipped with a group ordering. We say that $M \in \mathbb{Q}^{r \times n}$ is in the rank $r$ tropical variety $\mathcal{T}^r(I)$ if the initial ideal in $M(I)$ contains no monomials.

The points in the rank $r$ tropical variety $\mathcal{T}^r(I)$ are related to the points in the usual tropical variety $\mathcal{T}(I)$ by the following proposition. It is a corollary of Lemma 3.8.

Proposition 3.16. Let $\mathbb{Q}^r$ be equipped with the standard lexicographic ordering. Let $M \in \mathbb{Q}^{r \times n}$ and let $u_i \in \mathbb{Q}^n$ be the $i$-th row of $M$, $1 \leq i \leq r$. Then $M \in \mathcal{T}^r(I)$ if and only if $u_1 \in \mathcal{T}(I)$ and $u_i \in \mathcal{T}(\text{in}_{i-1}(\ldots \text{in}_1(I) \ldots))$ for all $1 < i \leq r$.

4. Valuation constructed from a weighting matrix

In this section we introduce two classes of quasivaluations on an algebra $A$. First is the class of weight quasivaluations (Definition 4.1). These are quasivaluations which are induced from a vector-valued weighting of indeterminates in a polynomial algebra $k[x]$ which presents $A$. When the weighting matrix lies in the Gröbner region, the corresponding weight quasivaluation possesses an adapted vector space basis (in the sense of Definition 2.26). We also describe the set of weight quasivaluations on $A$ as a piecewise linear object (Algorithm 2.11) always terminates. One of the important results in this section is that every subductive valuation is a weight valuation (Lemma 4.10).

4.1. Quasivaluation constructed from a weighting matrix. We start by introducing the notions of filtration and quasivaluation constructed out of a weighting matrix (in fact, we already saw these notions in disguise in Section 2.2 after Remark 2.14). Let $\pi : B \to A$ be a surjection of $k$-algebras, and let $\mathcal{F} = \{F_\alpha\}$ be an algebra filtration on $B$ by $k$-vector spaces. The pushforward filtration $\pi_\ast(\mathcal{F})$ on $A$ is defined by the set of spaces $\{\pi(F_\alpha)\}$. If $v$ is a quasivaluation on $B$ with corresponding filtration $\mathcal{F}_v$, we let $\pi_\ast(v)$ be the pushforward quasivaluation on $A$ corresponding to the filtration $\pi_\ast(\mathcal{F}_v)$.

Fix a group ordering $\succ$ on $\mathbb{Q}^r$. Each matrix $M \in \mathbb{Q}^{r \times n}$ defines a $\mathbb{Q}^r$-valued valuation $\tilde{\nu}_M : k[x] \setminus \{0\} \to \mathbb{Q}$ by the following rule. Let $p = \sum c_\alpha x^\alpha \in k[x]$. Define:

\[
\tilde{\nu}_M(p) = \text{MIN}\{M\alpha \mid c_\alpha \neq 0\}.
\]

Here MIN is computed with respect to $\succ$. We denote the filtration on $k[x]$ corresponding to $\tilde{\nu}_M$ by $\mathcal{F}_M$. Notice that the monomial basis of $k[x]$ is adapted to the filtration $\mathcal{F}_M$, in particular $F_{M, \geq a}$ is the span of monomials $x^\alpha$ with $M\alpha \geq a$.

Now as usual let $A$ be a finitely generated $k$-algebra and domain. Let $\pi : k[x] \to A$ be a surjective algebra homomorphism, i.e. a presentation of $A$, with $I = \ker(\pi)$.

Definition 4.1. With notation as above, the weight filtration on $A$ associated to $M \in \mathbb{Q}^{r \times n}$ is the pushforward filtration $\pi_\ast(\mathcal{F}_M)$. We denote the corresponding quasivaluation on $A$ by $\nu_M$. We refer to $\nu_M$ as the weight quasivaluation with weighting matrix $M$.

Lemma 4.2. For any $f \in A$ and $M \in \mathbb{Q}^{r \times n}$, the quasivaluation $\nu_M(f)$ is computed as follows:

\[
\nu_M(f) = \pi_\ast(\tilde{\nu}_M)(f) = \text{MAX}\{\tilde{\nu}_M(\tilde{f}) \mid \tilde{f} \in k[x], \pi(\tilde{f}) = f\}.
\]

Note that, as $\tilde{\nu}_M$ is defined by a minimum, the equation (4.2) is in fact a max-min formula.

24
Throughout the rest of the paper, we assume that the weighting matrix $M$ is chosen such that the maximum in (4.2) is attained for all $0 \neq f \in A$. This is the case for example if $M$ is chosen from the Gröbner region $\text{GR}^r(I) \subset \mathbb{Q}^{r \times n}$. In this case, the weight quasivaluation $\nu_M$ can be computed using a standard monomial basis as follows.

**Proposition 4.3.** With notation as above, let $M \in \text{GR}^r(I)$ and let $\mathcal{B} \subset A$ be the standard monomial basis for a monomial ordering $>$ with $M \in C_>(I)$. Then $\mathcal{B}$ is adapted to $\nu_M$. Moreover, let $0 \neq f \in A$ and write $f = \sum c_{\alpha} b_{\alpha}$ as a linear combination of basis elements $b_{\alpha} \in \mathcal{B}$, where $b_{\alpha}$ is the image of a standard monomial $x^\alpha$. Then $\nu_M(f)$ can be computed by:

$$
(4.3) \quad \nu_M(f) = \text{MIN}\{M\alpha \ | \ c_{\alpha} \neq 0\}.
$$

**Proof.** The inequality $\nu_M(f) \geq \text{MIN}\{\nu_M(b_{\alpha}) \ | \ c_{\alpha} \neq 0\}$ is immediate from the definition of a quasivaluation (Definition 2.25[1]). This in turn implies $\nu_M(f) \geq \text{MIN}\{M\alpha \ | \ c_{\alpha} \neq 0\}$. We need to show that the equality holds. Let $\tilde{f} = \sum c_{\alpha} x^{\alpha}$ and let $m = \text{MIN}\{M\alpha \ | \ c_{\alpha} \neq 0\}$. Suppose by contradiction that there is $\tilde{h} = \sum c'_\beta x^{\beta} \in k[x]$ such that $\pi(\tilde{h}) = f$ and moreover for every $\beta$ with $c'_\beta \neq 0$ we have $M\beta > m$. Let $p = \sum c_{\alpha} x^{\alpha} - \sum c'_\beta x^{\beta}$. Then $p \in I$ and $\text{in}_I(p)$ consists only of standard monomials $c_{\alpha} x^{\alpha}$. This implies that a nontrivial linear combination of images of standard monomials in $k[x]/\text{in}_M(I)$ is 0. The contradiction proves the claim. □

It follows from Lemma 3.7 and Proposition 4.3 that if $I$ is a homogeneous ideal with respect to a positive grading on $k[x]$ then any weight quasivaluation $\nu_M$ can be equipped with an adapted basis.

Let $M \in \mathbb{Q}^{r \times n}$ for some $r > 0$. To simplify the notation, from now on we denote the associated graded algebra of the weight quasivaluation $\nu_M$ by $\text{gr}_M(A)$. The following lemma describes the graded algebra $\text{gr}_M(A)$ in terms of the initial ideal $\text{in}_M(I)$ of $I \subset k[x]$. This observation is important for the main results of the paper.

**Lemma 4.4.** The associated graded algebra $\text{gr}_M(A)$ is isomorphic to $k[x]/\text{in}_M(I)$.

**Proof.** Consider the filtration on $k[x]$ by the spaces $F_{M, \geq a}$ and the associated pushforward filtration $\pi(F_{M, \geq a})$. For any $a \in \mathbb{Q}^r$, the pushforward space $\pi(F_{M, \geq a})$ can be identified with $F_{M, \geq a}/(F_{M, \geq a} \cap I)$. As such, the associated graded algebra $\text{gr}_M(A)$ is a direct sum of the following $k$-vector spaces:

$$(F_{M, \geq a}/F_{M, \geq a} \cap I)/(F_{M, > a}/F_{M, > a} \cap I).$$

Since $\text{in}_M(I)$ is homogeneous with respect to the $M$-grading on $k[x]$, we can also think of $k[x]/\text{in}_M(I)$ as a $\mathbb{Q}^r$-graded algebra. In particular, $k[x]$ is canonically isomorphic to the associated graded algebra $\text{gr}_M(k[x]) = \bigoplus_a F_{M, \geq a}/F_{M, > a}$, where $F_{M, \geq a}/F_{M, > a}$ is the vector space spanned by the images of monomials with $M$-degree $a$. The image of $\text{in}_M(I)$ under this isomorphism is the direct sum of the spaces $(F_{M, \geq a} \cap I)/(F_{M, > a} \cap I)$. Now the lemma follows from the following general fact about quotients from linear algebra. Let $W,U$ be subspaces of a vector space $V$, then:

$$(V/U)/(W/W \cap U) \cong (V/W)/(U/U \cap W) \cong V/(W + U).$$

□

By Proposition 4.3, if $M$ is chosen from the Gröbner region $\text{GR}^r(I)$, a standard monomial basis $\mathcal{B}$ for $M$ defines a basis $\tilde{\mathcal{B}}$ of $\text{gr}_M(A)$. In this case, the isomorphism in Lemma 4.4 above sends the image of a standard monomial in $\tilde{\mathcal{B}} \subset \text{gr}_M(A)$ to its image in $k[x]/\text{in}_M(I)$. 

25
Here is a simple example for illustration.

**Example 4.5.** Let \( A = \mathbb{k}[x] \) be the polynomial algebra in one indeterminate \( x \) and consider its presentation \( \mathbb{k}[x] \cong \mathbb{k}[x, y]/I \) where \( I = (x^2 - y) \). Thus we have the surjective homomorphism \( \pi : \mathbb{k}[x, y] \to \mathbb{k}[x] \) given by \( \pi(x) = x \) and \( \pi(y) = x^2 \). With notation as above, let \( r = 1 \) and consider the weight \( M = (1, 2) \in \mathbb{Q}^2 \). Then \( I \) is a homogeneous ideal with respect to the \( M \)-grading. It is easy to verify that \( \text{in}_M(x^2 - y) = x^2 - y \) and hence \( \text{in}_M(I) = I \). Also the pushforward filtration on \( A = \mathbb{k}[x] \) is just the grading by degree and thus \( \text{gr}_M(\mathbb{k}[x]) = \mathbb{k}[x] \cong \mathbb{k}[x, y]/I \) as expected.

Next, let \( M = (1, 3) \). In this case, one can compute the pushforward filtration on \( \mathbb{k}[x] \) as follows. For each \( a \geq 0 \) we have \( \pi(F_{M, \geq a}) = \text{span}\{x^m, x^{m+1}, \ldots \} \) where \( m = \lceil 2a/3 \rceil \).

It follows that the \( \text{gr}_M(\mathbb{k}[x]) \) is the graded algebra whose \( a \)-th graded piece is \( \mathbb{k} \) when \( a \equiv 0, 1 \pmod{3} \) and is 0 when \( a = 2 \pmod{3} \). One verifies that the quotient \( \mathbb{k}[x, y]/(x^2) \) is indeed isomorphic to this algebra. The isomorphism is given by sending the image of \( x \) (in \( \mathbb{k}[x, y]/(x^2) \)) to a nonzero element in degree 1 (in \( \text{gr}_M(\mathbb{k}[x]) \)) and sending the image of \( y \) to a nonzero element in degree 3. We remark that since the initial ideal \( \text{in}_M(I) = \langle x^2 \rangle \) is not prime, and thus the associated graded algebra \( \text{gr}_M(\mathbb{k}[x]) \) is not a domain, the quasivaluation \( \mathbb{v}_M \) is not a valuation.

### 4.2. The set of weight quasivaluations.

In this section we describe the set of weight quasivaluations on \( A \) coming from a given presentation.

As usual let \( \mathcal{B} = \{b_1, \ldots, b_n\} \) be a set of algebra generators for \( A \) giving rise to \( \pi : \mathbb{k}[x] \to A \) and let \( I = \ker(\pi) \). Let \( \mathcal{V}_\mathcal{B} \) denote the set of all weight quasivaluations \( \mathbb{v}_M \) on \( A \) induced from \( \pi \), for \( M \in \mathbb{Q}^{r \times n} \). Define the function \( \mathcal{T}_\mathcal{B} : \mathcal{V}_\mathcal{B} \to \mathbb{Q}^{r \times n} \) as follows. For each \( \mathbb{v}_M \in \mathcal{V}_\mathcal{B} \) let:

\[
\mathcal{T}_\mathcal{B}(\mathbb{v}_M) = (\mathbb{v}_M(b_1), \ldots, \mathbb{v}_M(b_n)).
\]

We would like to point out that the value \( \mathbb{v}_M(b_i) \) is not necessarily the \( i \)-th entry of \( M \). In fact, by Lemma 4.2 for each \( i \), \( \mathbb{v}_M(b_i) \) is given by the max-min formula:

\[
(4.4) \quad \mathbb{v}_M(b_i) = \text{MAX}\{\text{MIN}\{M\alpha \mid c_\alpha \neq 0\} \mid x_i - \sum_\alpha c_\alpha x^\alpha \in I\}.
\]

We remark that the map \( \mathcal{T}_\mathcal{B} \) is an extension of the usual tropicalization map in tropical geometry to the set of weight quasivaluations. We also define a **contraction map** \( \iota : \mathbb{Q}^{r \times n} \to \mathbb{Q}^{r \times n} \) by:

\[
\iota(M) = \mathcal{T}_\mathcal{B}(\mathbb{v}_M) = (\mathbb{v}_M(b_1), \ldots, \mathbb{v}_M(b_n)),
\]

for every \( M \in \mathbb{Q}^{r \times n} \). From (4.4) we see that \( \iota \) is a piecewise linear map.

The purpose of this section is to prove the proposition below.

**Proposition 4.6.** We have the following:

1. \( \mathbb{v}_M = \mathbb{v}_{\iota(M)}, \forall M \in \mathbb{Q}^{r \times n} \).
2. \( \iota(M) = \iota(M'), \forall M, M' \in \mathbb{Q}^{r \times n} \).
3. The map \( \mathcal{T}_\mathcal{B} \) is one-to-one, i.e. any weight quasivaluation on \( A \) is determined by its values on \( \mathcal{B} \). In particular, for \( M, M' \in \mathbb{Q}^{r \times n} \), the equality \( \mathbb{v}_M = \mathbb{v}_{M'} \) holds if and only if \( \iota(M) = \iota(M') \).
4. If \( M \) is contained in the tropical variety \( \mathcal{T}(I) \subset \mathbb{Q}^{r \times n} \), namely those weights for which \( \text{in}_M(I) \) contains no monomial, then \( \iota(M) = M \).

We need the following lemma.
Lemma 4.7. Let $M \in \mathbb{Q}^{r \times n}$ and let $w_1, \ldots, w_n$ (respectively $w'_1, \ldots, w'_n$) denote the column vectors of $M$ (respectively the column vectors of $\iota(M)$). Then for all $1 \leq i \leq n$ we have $w'_i \succeq w_i$, and $w'_i > w_i$ if and only if $x_i \in \text{in}_M(I)$.

Proof. The inequality $w'_i \succeq w_i$ holds by definition. Also $w'_i > w_i$ if and only if $x_i$ is the $M$-initial form of some $x_i - \sum c_a x^a \in I$.

Proof of Proposition 4.6. Parts (2) and (3) are straightforward corollaries of (1). Part (4) follows immediately from Lemma 4.7. So it suffices to prove (1). We claim that $F_{M, \succeq a} = F_{\iota(M), \succeq a}$ for all $a \in \mathbb{Q}^r$. From Lemma 4.7 we see that $F_{M, \succeq a} \subset F_{\iota(M), \succeq a}$. Now take $f \in F_{\iota(M), \succeq a}$ with $p(x)$ a polynomial such that $\pi(p(x)) = f$. Suppose that the minimum $M$-degree among the monomials in $p(x)$ is smaller than $a$, but that the minimum $\iota(M)$-degree is larger than $a$. If this is so then a monomial achieving this minimum must involve an $x_i$ at which $M$ and $\iota(M)$ differ. It follows that we may replace $x_i$ with $\sum c_a x^a$ as in Lemma 4.7 obtaining a polynomial $q(x)$ which still represents $f$ and for which each monomial has higher $M$-degree. As a consequence $p(x)$ cannot not achieve the maximum values among presentations of $f$ with respect to $M$. The contradictions shows $F_{\iota(M), \succeq a} = F_{M, \succeq a}$. □

4.3. Subductive valuations. Now we introduce the class of subductive valuations which is a primary object of study in this paper. As usual $A$ denotes a finitely generated algebra and domain.

Definition 4.8. (Subductive valuation) A valuation $v : A \setminus \{0\} \to \mathbb{Q}^r$ is said to be a subductive valuation if there is a finite Khovanskii basis $B \subset A$ for $v$ such that the subduction algorithm (Algorithm 2.11) always terminates in finite time for any $f \in A$.

Remark 4.9. We note that a Khovanskii basis $B$ for which the subduction algorithm always terminates is automatically an algebra generating set for $A$ (Algorithm 2.11). A subductive valuation facilitates doing computations in $A$ by means of its associated graded algebra $\text{gr}_v(A)$.

As the following important lemma shows, the defining condition of a subductive valuation is strong enough to ensure that such a valuation is actually a weight valuation. Its proof is essentially the proof of Theorem 2.16 ((1) ⇒ (2)).

Lemma 4.10. Let $v : A \setminus \{0\} \to \mathbb{Q}^r$ be a subductive valuation with a finite Khovanskii basis $B = \{b_1, \ldots, b_n\}$ and let $\pi : \mathbb{K}[x] \to A$ be its corresponding presentation. Then $v = v_M$ where $M \in \mathbb{Q}^{r \times n}$ is the weighting matrix whose column vectors are $v(b_1), \ldots, v(b_n)$.

Corollary 4.11. Suppose $A = \bigoplus_{i \geq 0} A_i$ is positively graded and $v$ is a subductive valuation with a finite Khovanskii basis $B$ consisting of homogenous elements. Then $(A, v)$ has an adapted basis.

Proof. The assumptions imply that the presenting ideal $I$ is homogeneous and hence its Gröbner region $\text{GR}'(I)$ is the whole $\mathbb{Q}^r$. By Lemma 4.10 we know that $v = v_M$ is a weight valuation. The claim now follows from Proposition 4.3. □

5. Valuations from prime cones

As before, let $A$ be a finitely generated algebra and domain and let $B$ be a finite set of algebra generators for $A$ giving rise to a presentation $A \cong \mathbb{K}[x]/I$. This section concerns the proof of one of the main results of the paper (Theorem 4 from the introduction). First we describe the construction of a valuation on $A$ from a prime cone $C \subset \mathcal{T}(I) \cap \text{GR}(I)$ such
that \( B \) is a finite Khovanskii basis for this valuation (see below for the definition of a prime cone). Moreover, we show that this valuation has an adapted basis (Definition 2.26). When \( A \) is positively graded and \( B \) consists of homogeneous elements, the valuation corresponding to \( C \) is subductive (Definition 4.8).

Let \( I \subset k[x] \) be a prime ideal and let \( C \subset T(I) \) be an open cone in the tropical variety of \( I \) such that for any \( u_1, u_2 \in C \) we have \( \text{in}_{u_1}(I) = \text{in}_{u_2}(I) \). For example, this is the case if \( C \) is chosen from the Gröbner fan of the homogenization \( I_h \) of \( I \). Recall that this common initial ideal is denoted by \( \text{in}_C(I) \).

**Definition 5.1.** Let \( C \subset T(I) \) be an open cone. We call \( C \) a prime cone if the corresponding initial ideal \( \text{in}_C(I) \) is a prime ideal.

Take a finite subset \( u = \{u_1, \ldots, u_r\} \subset C \). We denote the \( r \times n \) matrix whose \( j \)-th row is \( u_j \) by \( M \) and regard it as a \( \mathbb{Q}^r \)-weighting matrix on \( k[x] \), where \( \mathbb{Q}^r \) is given the standard lexicographic ordering. We denote the \( i \)-th column of \( M \) by \( v_i \in \mathbb{Q}^r \).

**Proposition 5.2.** Let \( C \) be a prime cone that lies in the Gröbner region \( \text{GR}(I) \). We have the following:

1. The weight quasivaluation \( v_M \) is in fact a valuation with rank equal to \( \text{rank}(M) \).
2. The associated graded algebra \( \text{gr}_M(A) \) is isomorphic to \( k[x]/\text{in}_C(I) \).
3. The value semigroup \( S(A,v_M) \) is generated by the column vectors of \( M \), which are in fact the vectors \( v_M(b_1), \ldots, v_M(b_n) \). Consequently, the Newton-Okounkov cone \( P(A,v_M) \) is the cone generated by these column vectors.
4. If the cone \( C \) has maximal dimension \( d = \dim(A) \) and the linear span of the set \( u \) is also \( d \)-dimensional then the valuation \( v_M \) has rank \( d \). If, in addition, we assume that \( k \) is algebraically closed then \( v_M \) is a valuation with one-dimensional leaves.

**Remark 5.3.** We note that if \( A \) is positively graded and we choose a set of homogeneous generators for \( A \), any prime cone lies in the Gröbner region.

**Proof of Proposition 5.2.** By Lemma 3.8 we have \( \text{in}_M(I) = \text{in}_{u_r}(\cdots(\text{in}_{u_1}(I))) \). Since by assumption \( \text{in}_{u_1}(I) = \cdots = \text{in}_{u_n}(I) = \text{in}_C(I) \) we conclude that \( \text{in}_M(I) = \text{in}_C(I) \) which is assumed to be a prime idea. On the other hand, by Lemma 4.4 we know that \( \text{gr}_v(A) \cong k[x]/\text{in}_M(I) \). Since the quotient \( k[x]/\text{in}_M(I) \) is a domain we see that \( v_M \) is indeed a valuation. Part (2) and (3) now follow from Part (1) and Lemma 2.10. Part (4) follows from (1) and Theorem 2.3. \( \square \)

**Proposition 5.4.** With notation as above, for \( u_i \in u \) let \( v_{u_i} : A \setminus \{0\} \to \mathbb{Q} \) denote the corresponding rank 1 valuation. Then for any \( b_j \in B \) we have \( v_{u_i}(b_j) = (u_i)_j \), the \( j \)-th coordinate of the vector \( u_i \in \mathbb{Q}^n \).

**Proof.** Follows from Proposition 4.6. \( \square \)

**Remark 5.5.** (1) If we assume that \( C \) is taken from the Gröbner fan of the homogenization \( I_h \) of \( I \), or if \( I \) is itself homogeneous, then some of the \( u_i \) may be taken from faces of the closure of \( C \), provided that the sum \( \sum u_i \) is in \( C \). To show this, note that by Proposition 3.11 we can use the above argument (in the proof of Proposition 5.2) with \( u = u_1 + \cdots + u_r \) in place of \( u_1 \).

---

11 As mentioned in the introduction, by abuse of terminology, we may occasionally refer to a closed cone as prime, in which case we mean that its relative interior is prime.
(2) The proof of Proposition 5.2 can also be used in the case that $A$ is the coordinate ring of a very affine variety, i.e. when $A$ is presented as a quotient of a Laurent polynomial algebra.

The next proposition shows that the value semigroup $S(A, v_M)$, up to linear isomorphism, depends only on the cone $C$. Before we state this result, let us define what we mean by linear isomorphism of subsets of vector spaces. Let $S \subset \mathbb{Q}^r$ and $S' \subset \mathbb{Q}'^r$ be two subsets. We say that $S$ is linearly isomorphic to $S'$ if there exists a $\mathbb{Q}$-linear map $T : \mathbb{Q}'^r \to \mathbb{Q}^r$ such that $T$ restricts to a bijection between $S$ and $S'$.

**Proposition 5.6.** Suppose the span of $u$ has dimension $\dim(C)$. Then, up to linear isomorphism, the semigroup $S(A, v_M)$ (and hence the cone $P(A, v_M)$) depend only on $C$.

**Proof.** Let $u = \{u_1, \ldots, u_r\}$, $u' = \{u'_1, \ldots, u'_s\} \subset C$ be two subsets with corresponding weighting matrices $M \in \mathbb{Q}^{r \times n}$, $M' \in \mathbb{Q}^{s \times n}$ respectively. By assumption the spans of $u$ and $u'$ are the same. Hence every row of $M$ is a linear combination of the rows of $M'$. It follows that the $M$-degree of two monomials $x^\alpha$ and $x^\beta$ are the same if and only if their $M'$-degrees are the same. Now consider $R = \text{gr}_M(A)$ and $R' = \text{gr}_{M'}(A)$. The algebras $R$ and $R'$ are graded by $S = S(A, v_M)$ and $S' = S(A, v_M')$ respectively. By Proposition 5.2(2) we know that $R$ and $R'$ are isomorphic (because they are both isomorphic to $k[x]/\text{in}_c(I)$). Moreover, by what we said above, the isomorphism sends each graded component $R_a$, $a \in S$ to another graded component $R'_a$, $a' \in S'$. One verifies that the map $a \mapsto a'$ gives a linear isomorphism between $S$ and $S'$.

Finally, let us assume that the algebra $A$ is positively graded, i.e. $A = \bigoplus_{i \geq 0} A_i$, and the algebra generating set $B$ consists of homogeneous elements of degree 1. It follows that $I$ is a homogeneous ideal and moreover the vector $(-1, \ldots, -1)$ belongs to the lineality space of $I$ and hence lies in every cone in the Gröbner fan of $I$. Thus, we can take the vector $u_1 \in u$ to be $(-1, \ldots, -1)$. In this case, one observes that the valuation $v_M$ constructed above is such that for every $0 \neq f \in A$, the first component of $v_M(f)$ is $-\deg(f)$. (Thus after dropping the minus sign in $-\deg(f)$, the valuation $v_M$ is of the form (1.1).)

The following is an immediate corollary of Proposition 5.2(3) and Proposition 5.6.

**Corollary 5.7.** With notation as above we have the following:

(1) The Newton-Okounkov body $\Delta(A, v_M)$ is the convex hull of the column vectors of $M$ (recall that the $i$-th column vector of $M$ coincides with $v_M(b_i)$).

(2) Up to linear isomorphism, the convex body $\Delta(A, v_M)$ depends only on $C$.

Next Proposition states that the valuation $v_M$ has an adapted basis (Proposition 5.8), and moreover, this adapted basis has nice properties with respect to multiplication (Proposition 5.9). This implies that $v_M$ is a subductive valuation.

When $C$ lies in $\text{GR}(I)$ we can find a monomial ordering on $k[x]$ such that the cone $C$ is a face of a maximal cone $C_\omega$ in the Gröbner region $\text{GR}(I)$. Let $B \subset k[x]/I \cong A$ be a standard monomial basis with respect to $>$. As before, we take a subset $u = \{u_1, \ldots, u_r\} \subset C$ and let $M$ be the $r \times n$ matrix matrix whose $j$-th row is $u_j$, for all $j$. As usual we regard $M$ as a $\mathbb{Q}^r$-weighting matrix on $k[x]$, where $\mathbb{Q}^r$ is given the standard lexicographic ordering.

**Proposition 5.8.** The standard monomial basis $B$ is adapted to $v_M$. Moreover, we have $\text{in}_{\omega}(\text{in}_M(I)) = \text{in}_{\omega}(I)$, that is, $M \in \text{GR}^r(I)$ (see Definition 3.2).

**Proof.** By Lemma 3.8 we have $\text{in}_M(I) = \text{in}_{u_1}(\ldots \text{in}_{u_r}(I) \ldots)$. Since $u \subset C \subset \text{GR}(I)$, by Proposition 3.11 we have $\text{in}_M(I) = \text{in}_{u_1 + \ldots + u_r}(I)$. It follows that $M \in \text{GR}^r(I)$ and $\text{in}_{\omega}(\text{in}_M(I)) = \text{in}_{\omega}(I)$. Proposition 4.3 then implies that $B$ is adapted to $v_M$. □
For \( u \in C \) we can also consider the rank one valuations \( v_u : A \setminus \{0\} \to \mathbb{Q} \) associated to the weight \( u \). Proposition 4.3 in particular implies that the basis \( B \) is also adapted to \( v_u \). The valuations \( v_u \) and the basis \( B \) are related as follows.

**Proposition 5.9.** We have the following:

1. Let \( u_1, u_2 \in C \) and \( c_1, c_2 \in \mathbb{Q}_{\geq 0} \) and put \( u = c_1 u_1 + c_2 u_2 \). Then for any basis element \( b \in B \) we have \( v_u(b) = c_1 v_{u_1}(b) + c_2 v_{u_2}(b) \).
2. Let \( \{u_1, \ldots, u_r\} \subset C \) such that its span has maximal dimension \( \dim(C) \). As above let \( v_M \) denote its associated valuation. Let \( b_\alpha, b_\beta \in B \). Consider the expansion of the product \( b_\alpha b_\beta \) in the basis \( B \):

\[
b_\alpha b_\beta = \sum c_{\alpha, \beta}^\gamma b_\gamma,
\]

where the \( c_{\alpha, \beta}^\gamma \in k \). Then for every \( \gamma \), with \( c_{\alpha, \beta}^\gamma \neq 0 \), and every \( i = 1, \ldots, r \) we have \( v_u(b_i) \geq v_u(b_\alpha) + v_u(b_\beta) \). Moreover, there exits \( b_\eta \in B \), with \( c_{\alpha, \beta}^\eta \neq 0 \), such that, for every \( i \), we have \( v_u(b_\eta) = v_u(b_\alpha) + v_u(b_\beta) \).
3. If \( k \) is assumed to be algebraically closed and \( C \) is a cone of maximal dimension \( d = \dim(A) \), then the basis element \( b_\eta \) in the part (2) is unique.

**Proof.** Part (1) and the first assertion in (2) are direct consequences of Proposition 4.3. To prove the second assertion in (2) note that if the equality was not achieved for some \( \gamma \), then the product \( b_\alpha b_\beta \) would be 0 in the associated graded \( gr_\gamma(A) \) which would imply that \( v_M \), associated to \( u \), is not a valuation. Finally, by Theorem th-full-rank-1-dim-leaves, the assumptions in (3) imply that the valuation \( v_M \) is a valuation with one-dimensional leaves. This finishes the proof. \( \square \)

6. **Prime cones from valuations**

In this section we associate a prime cone (which lies in the tropical variety of the ideal presenting our algebra) to a weight valuation. Note that since any subductive valuation is a weight valuation (Lemma 6.10), this in particular works for all subductive valuations.

Before we do this, first we make an observation which applies to all valuations. As usual we consider the group \( \mathbb{Q}^r \), for some \( r > 0 \), equipped with a group ordering \( \succ \).

**Proposition 6.1** (Higher rank tropicalization map). Let \( v : A \setminus \{0\} \to \mathbb{Q}^r \) be a valuation (not necessarily subductive or with a finite Khovanskii basis). Let \( B = \{b_1, \ldots, b_n\} \subset A \) be a set of algebra generators and let \( I \subset k[x] \) be the ideal of relations among the \( b_i \). Let \( M = M(B,v) \) be the matrix whose columns are \( v(b_1), \ldots, v(b_n) \). Then \( M \) belongs to the rank \( r \) tropical variety \( T^r(I) \) (Definition 3.15).

**Proof.** The proof is the same as the usual proof when the valuation has rank 1. We need to show \( \text{in}_M(I) \) does not contain a monomial. In light of Lemma 3.3 it suffices to show that for any nonzero \( f \in I \), the initial form \( \text{in}_M(f) \) is not a monomial. Let \( f = \sum c_\alpha x^\alpha \) and suppose by contradiction that \( \text{in}_M(f) \) is the monomial \( c_\beta x^\beta \). Here \( \beta = (\beta_1, \ldots, \beta_n) \) is the unique exponent at which \( \text{MIN}\{Ma \mid c_\alpha \neq 0\} \) is attained. This then implies that \( v(f(b_1, \ldots, b_n)) = v(b_1^{\beta_1} \cdots b_n^{\beta_n}) = M\beta \). This contradicts the fact that \( f \in I \) which means \( f(b_1, \ldots, b_n) = 0 \). \( \square \)

We think of \( v \mapsto M \) as a higher rank generalization of the tropicalization map in usual tropical geometry. The above (Proposition 6.1) has also been observed in [FR16].

Now let us assume that \( \mathbb{Q}^r \) is equipped with the standard lexicographic order. Let \( B = \{b_1, \ldots, b_n\} \) be a set of algebra generators giving rise to a presentation \( A \cong k[x]/I \).
Let \( M \in \mathbb{Q}^{r \times n} \) be a matrix such that the corresponding weight quasi-valuation \( v = v_M : A \setminus \{0\} \to \mathbb{Q}^r \) is indeed a valuation. The next proposition constructs a prime cone \( C_v \) in the tropical variety \( T(I) \) associated to the valuation \( v \).

**Proposition 6.2.** With notation as above, there exists an open cone \( C_v \) in the tropical variety \( T(I) \) with \( \dim(C_v) \geq \text{rank}(M) \) such that \( \text{in}_M(I) = \text{in}_v(I) \), for any \( u \in C_v \). Thus, if we denote the common initial ideal \( \text{in}_u(I), u \in C_v \), by \( \text{in}_{C_v}(I) \), we have:

\[
gr_v(A) \cong k[x]/\text{in}_{C_v}(I).
\]

In particular, if \( v \) has maximal rank \( d = \dim(A) \) then \( C_v \) has dimension \( d \).

**Proof.** We pass to the homogenization. Proposition 3.10 implies that there is \( u \in \mathbb{Q}^n \) such that \( \text{in}_{(0,u)}(I_h) = \text{in}_{(0,M)}(I_h) \), and furthermore \( \text{in}_v(I) = \text{in}_M(I) \). Let \( C \in \Sigma(I_h) \) be an open cone that contains \( (0,u) \) and let \( G_>(I_h) \) be an appropriate reduced Gröbner basis for \( I_h \). For any \( g \in G_>(I_h) \), the initial form \( \text{in}_{(0,M)}(g) \) is a polynomial \( \sum p_i(x)x_i^m \), such that each \( p_i(x) \) is homogeneous with respect to \( M \). Let \( u_1, \ldots, u_n \) denote the rows of \( M \) and let \( H \) be its row span over \( \mathbb{Q} \). Note that each \( p_i(x) \) is homogeneous with respect to each \( u_j \). It follows that there is some \( \epsilon > 0 \) such that any \( u' \) in the ball \( B(0,\epsilon) \subset H \) has the property \( \text{in}_{(0,u)+(0,u')} = \text{in}_{(0,u)}(g) \) for all \( g \in G_>(I_h) \). Since \( \dim(H) = r \) we conclude that \( \dim(C \cap \mathbb{Q}^n) = r \). The remaining parts of the proposition follow from the fact that if \( v \) is a valuation, then \( C_v \) is a prime cone. This implies that \( C_v \subset T(I) \) and that it is of dimension at most \( d \). \( \square \)

**Remark 6.3.** As above let \( B = \{b_1, \ldots, b_n\} \) be a set of algebra generators. Let \( v : A \setminus \{0\} \to \mathbb{Q}^r \) be a valuation and let \( M \) be the matrix whose columns are \( v(b_1), \ldots, v(b_n) \). (1) By Lemma 4.10 if we assume that \( v \) is subductive with Khovanski basis \( B \), then \( v = v_M \) is a weight valuation. (2) If we do not assume that \( v \) is subductive then by Proposition 6.1 we still can find a cone \( C \) in the tropical variety \( T(I) \) such that \( \text{in}_M(I) = \text{in}_C(I) \). But we cannot in general conclude that \( v = v_M \) and hence we do not know that \( \text{gr}_v(A) \cong k[x]/\text{in}_C(I) \). Also \( C \) is not necessarily a prime cone.

**Remark 6.4.** The proof of Proposition 6.2 implies that the cone \( C_v \) can be described using a reduced Gröbner basis of the homogenized ideal \( I_h \).

The next proposition relates the construction of a valuation \( v_M \) in Section 5 and the construction of a prime cone \( C_v \) in this section.

With notation as before, let \( v = v_M : A \setminus \{0\} \to \mathbb{Q}^r \) be a weight valuation with associated prime cone \( C_v \). Take a subset \( u = \{u'_1, \ldots, u'_s\} \subset C_v \) whose span has dimension \( \dim(C_v) \). Let \( M' \) be the matrix with rows \( u'_1, \ldots, u'_s \). Let \( v_{M'} \) be the corresponding valuation (as in Section 5). We have the following.

**Proposition 6.5.** The value semigroups \( S(A, v_M) \) and \( S(A, v_{M'}) \) are linearly isomorphic (in the sense of paragraph before Proposition 5.6). Consequently, the cones \( P(A, v_M) \) and \( P(A, v_{M'}) \) are also linearly isomorphic.

**Proof.** Both associated graded algebras \( \text{gr}_{v_M}(A) \) and \( \text{gr}_{v_{M'}}(A) \) are isomorphic to \( k[x]/\text{in}_M(I) \) for any \( u' \in C_v \). Moreover, the isomorphisms identify the images of the \( b_i \). Now as in the proof of Proposition 5.6 the value semigroup of \( v_{M'} \) is isomorphic to the value semigroup of \( v_M \). \( \square \)
7. Compactifications and degenerations

In this section we use a prime cone $C$ in the tropical variety $T(I)$, for some presentation $A \cong \mathbb{k}[x]/I$, to construct a compactification of $X = \text{Spec} (A)$. As a byproduct, when the cone $C$ has maximal dimension $d = \dim(A)$, we also get a toric degeneration of $X$.

This construction closely resembles the “geometric tropicalization” in [HKT06], [ST08], [Tev07].

We use notation as before. To simplify the discussion we assume that the cone $C$ lies in the negative orthant, i.e. $C \subset T^-(I) = T(I) \cap \mathbb{Q}^n_{\leq 0}$. We will use results in Section 5. More specifically, let $u = \{u_1, \ldots, u_r\} \subset C$. For simplicity we assume that the $u_i$ are linearly independent and $r = \dim(C)$. Let $M = M_u \in \mathbb{Q}^{m \times n}$ be the matrix whose rows are $u_1, \ldots, u_r$. Let $\mathfrak{v}_M$ be the corresponding valuation as constructed in Section 5. We recall that for every $i = 1, \ldots, n$, the $i$-th column of $M$ is the vector $\mathfrak{v}_M(b_i)$ which in turn is equal to the vector $(\mathfrak{v}_{u_i}(b_i), \ldots, \mathfrak{v}_{u_r}(b_i))$. Here $\mathfrak{v}_{u_i}$ is the rank 1 valuation associated to $u_i \in C$. We also know that the rank of the valuation $\mathfrak{v}_M$ is equal to $\text{rank}(M) = r$ (Propositions 5.2 and 5.4). Since $C \subset T^-(I)$ is always contained in the Gröbner region $\text{GR}(I)$, by Proposition 5.8 there is an adapted basis $\mathbb{B}$ for $(A, \mathfrak{v}_M)$ (in fact, $\mathbb{B}$ can be taken to be a standard monomial basis for $I$ and some monomial ordering $>$ such that $M \in C_>(I)$).

Without loss of generality, and after a linear change of coordinates in $\mathbb{Q}^r$ if needed, we can assume that the value semigroup of $\mathfrak{v}_M$ lies in $\mathbb{Z}^r$.

To construct our compactification, we choose one additional piece of information, namely a lattice point $\delta = (\delta_1, \ldots, \delta_r) \in \mathbb{Z}^r$ which lies in $P^r(A, \mathfrak{v}_M)$, the relative interior of the Newton-Okounkov cone (Definition 2.19).

We construct a projective compactification $\bar{X}_{u, \delta} \supset X$. We will give different constructions of this compactification:

(i) As Proj of a certain $\mathbb{Z}_{\geq 0}$-graded algebra $T_{u, \delta}(A)$.

(ii) As the GIT quotient, at $\delta$, of an affine variety $E_u$ by a natural action of the torus $\mathbb{G}_m^r$.

(iii) When the cone $C$ has maximal dimension $r = d = \dim(A)$, we can realize the compactification $\bar{X}_{u, \delta}$ as the closure of $X$ embedded into a projective toric variety $Y_{u, \delta}$.

7.1. Rees algebras. In this section we define a generalized Rees algebra $R_u(A)$. It plays the main role in the construction of our compactification.

Throughout Section 4, $\geq$ denotes the partial order on $\mathbb{Q}^r$ obtained by comparing the vectors componentwise. Namely, $(r_1, \ldots, r_r) \geq (s_1, \ldots, s_r)$ if and only if $r_i \geq s_i$ for all $i$.

As above, let $\mathbb{B} \subset A$ be the vector space basis for $A$ adapted to the valuation $\mathfrak{v}_M$. Beside the valuation $\mathfrak{v}_M$ we can consider the rank 1 valuations $\mathfrak{v}_{u_i}$ corresponding to the vectors $u_i \in u$. For $r = (r_1, \ldots, r_r)$ we define the set $\mathbb{B}_r$ by:

$\mathbb{B}_r = \{b \in \mathbb{B} \mid \mathfrak{v}_{u_i}(b) = r_i, \forall i = 1, \ldots, r\} \subset \mathbb{B}$.

We note that since $C \subset \mathbb{Q}^n_{\leq 0}$, the set $\mathbb{B}_r$ is nonempty only for $r \in \mathbb{Z}^r_{\leq 0}$. For $r \in \mathbb{Z}^r_{\leq 0}$ we then define the subspaces $W_u(r)$ and $F_u(r) \subset A$ as follows:

$W_u(r) = \text{span}(\mathbb{B}_r)$,

$F_u(r) = \bigoplus_{s \geq r} W_u(s) = \text{span}(\bigcup_{s \geq r} \mathbb{B}_s)$.

Clearly, $\{F_u(r)\}_{r \in \mathbb{Z}^r_{\leq 0}}$ is a multiplicative filtration of $A$ (see Proposition 5.9).
Consider the Laurent polynomial algebra \( A[t^\pm] = A[t_1^\pm, \ldots, t_r^\pm] \), where we have used \( t \) as an abbreviation for the indeterminates \((t_1, \ldots, t_r)\). Also, given \( r = (r_1, \ldots, r_r) \) we will write \( t^r \) to denote the monomial \( t_1^{r_1} \cdots t_r^{r_r} \). The Rees algebra \( R_\sigma(A) \) is the subalgebra of the Laurent polynomial algebra \( A[t^\pm] \) defined by:

\[
R_\sigma(A) = \bigoplus_{r \in \mathbb{Z}^{\geq 0}_r} F_\sigma(r) t^{-r} \subset \bigoplus_{r \in \mathbb{Z}^r} A t^{-r} = A[t^\pm].
\]

Let \( \phi : k[t] \to R_\sigma(A) \) be the homomorphism obtained by sending \( t_i \) to \( t_i^{-1}u_i \), for all \( i \). Here \( c_i = (0, 1, \ldots, 0) \) denotes the \( i \)-th standard basis element in \( \mathbb{Z}^r \). The homomorphism \( \phi \) gives \( R_\sigma(A) \) the structure of a \( k[t] \)-module. We let \( E_u \) denote the affine scheme \( \text{Spec}(R_\sigma(A)) \) defined by this Rees algebra. The next proposition establishes basic properties of the scheme \( E_u \) and its relationship to \( X \). We leave the proof of this proposition to the reader.

**Proposition 7.1.** As above, let \( R_\sigma(A) \) be the Rees algebra of \( A \) with respect to \( u \subset C \). We then have:

1. The map \( \phi : k[t] \to R_\sigma(A) \) defines a flat family \( \pi : E_u \to A^r \).
2. There is a natural action of the torus \( G_m^r \) on \( E_u \) which lifts the natural action of \( G_m^r \) on \( A^r \).
3. \( \text{Spec}(A[t^\pm]) = X \times G_m^r \) is the complement of the hypersurface \( V_u \subset E_u \) defined by the equation \( t_1 \cdots t_r = 0 \).

Next, we describe the fibers of the map \( \pi : E_u \to A^r \). By Proposition 7.1(2, 3), for any \( c = (c_1, \ldots, c_r) \) with \( c_i \neq 0 \), for all \( i \), the fiber \( \pi^{-1}(c) \) is isomorphic to \( X \). We will see below that the other fibers of the family are all degenerations of \( X \) coming from subsets of \( u \). Let \( \sigma \subset u \). Analogous to \( W_u(r) \) and \( F_u(r) \), given \( r' = (r'_i)_{u_i \in \sigma} \subset \mathbb{Z}^\sigma \) we can define \( W_\sigma(r') = \text{span}\{b \in B \mid \nu_u(b) = r'_i, \forall u_i \in \sigma\} \) and \( F_\sigma(r') = \text{span}\{b \in B \mid \nu_u(b) = r'_i, \forall u_i \in \sigma\} \). We then have the direct sum decomposition \( A = \bigoplus_{r'} W_\sigma(r') \). Let \( \text{gr}_\sigma(A) \) denote the associated graded algebra of the filtration \( \{F_\sigma(r')\}_{r' \in \mathbb{Z}^{\sigma}_{\leq 0}} \) on \( A \). Proposition 5.9 implies that \( \text{gr}_\sigma(A) \) has no zero divisors and hence this filtration must come from a valuation.

**Proposition 7.2.** Let \( c_\sigma = (c_{\sigma,1}, \ldots, c_{\sigma,r}) \subset \mathbb{Z}^\sigma \) be the vector of 0’s and 1’s defined by:

\[
c_{\sigma,i} = \begin{cases} 0 & u_i \in \sigma \\ 1 & u_i \notin \sigma,
\end{cases}
\]

for all \( i = 1, \ldots, r \). Then the fiber \( \pi^{-1}(c_\sigma) \) is isomorphic to \( X_\sigma = \text{Spec}(\text{gr}_\sigma(A)) \).

**Proof.** Specializing \( t_i = 1 \) for \( u_i \notin \sigma \) yields an algebra graded by \( \mathbb{Z}^\sigma_{\leq 0} \). For every \( r' \in \mathbb{Z}^\sigma \), the corresponding graded component is:

\[
F_\sigma(r') = \sum_{r|_{\sigma} = r'} F_u(r).
\]

Also, specializing \( t_i = 0 \) for \( u_i \in \sigma \) yields an algebra graded by \( \mathbb{Z}^\sigma_{\leq 0} \) with the graded components:

\[
F_\sigma(r') / \sum_{s' \leq r'} F_\sigma(s'),
\]

for \( r' \in \mathbb{Z}^\sigma \). It is straightforward to check that \( F_\sigma(r') \) has a vector space basis consisting of the images of those \( b \in B \) with \( \nu_u(b) = r_i \) for \( u_i \in \sigma \). It follows that these graded
components can be identified with the space \( W_\sigma(r') \). We leave it to the reader to check that the multiplication operation is likewise the same as in \( \text{gr}_\sigma(A) \).

Proposition 7.2 and Proposition 7.1(2) imply the following:

**Corollary 7.3** (Toric degeneration of \( \sigma \)). All fibers of the family \( \pi : E_u \to \mathbb{A}^r \) are reduced and irreducible. Moreover, these fibers are degenerations of \( X \) corresponding to valuations constructed from subsets of \( u \). In particular, the fiber over the origin is \( \text{Spec}(\text{gr}_{\nu_M}(A)) \). Moreover, if \( r = d = \dim(A) \), the fiber over the origin is \( \text{Spec}(k[S(A, \nu_M)]) \) which is a (not necessarily normal) affine toric variety (see Proposition 2.4).

**Remark 7.4.** (1) In all the above constructions/definitions, instead of the partial order \( > \) we can use a group ordering \( \succ \) on \( \mathbb{Z}^r \) which refines \( > \). For example we can take \( \succ \) to be a lexicographic order. It follows from Proposition 5.9 that the resulting associated graded algebra \( \text{gr}_\nu(A) \) is the same as the associated graded algebra \( \text{gr}_\nu(A) \) corresponding to the filtration by the \( F_u(r) \). Note that the associated graded \( \text{gr}_\nu(A) \) is in fact the associated graded \( \text{gr}_{\nu_M}(A) \) of the valuation \( \nu_M \).

(2) As far as the authors know, the construction of the Rees algebra associated to a valuation is due to B. Teissier (see [Tei03] and in particular Proposition 2.2 in there which is very close to our Proposition prop-Rees). Also [And13, Proposition 3] is a 1-parameter version of [Tei03, Proposition 2.2].

7.2. The compactification of \( X \). We can now construct the compactification \( \bar{X}_{u,\delta} \) of \( X \). Since the Rees algebra \( R_u(A) \) is by definition \( \mathbb{Z}^r \)-graded, the scheme \( E_u = \text{Spec}(R_u(A)) \) comes with a natural action of the torus \( \mathbb{G}_m^r \). We define \( \bar{X}_{u,\delta} \) to be the GIT quotient \( E_u//\delta \mathbb{G}_m^r \). Equivalently, from definition of the GIT quotient, we can realize this scheme as \( \text{Proj} \) of the \( \mathbb{Z}_{\geq 0} \)-graded subalgebra

\[
T_u(A) = \bigoplus_{N \geq 0} F_u(N\delta)t^{-N\delta} \subset R_u(A).
\]

The affine scheme \( E_u \) is of finite type, so it follows that \( \bar{X}_{u,\delta} \) is projective.

We define valuation \( \bar{\nu}_M : T_u(A) \to \mathbb{Z}_{\geq 0} \times \mathbb{Q}_{\leq 0} \) as follows. For any \( 0 \neq f = \sum_{i=0}^{m} f_i t^{-i} \), we let:

\[
\bar{\nu}_M(f) = (N, \nu_M(f_N)),
\]

where \( N = \text{MIN}\{i \mid f_i \neq 0\} \). Similarly, for any \( u \in C \) we can define valuation \( \bar{\nu}_u : T_u(A) \to \mathbb{Z}_{\geq 0} \times \mathbb{Q}_{\leq 0} \).

We observe that the value semigroup of \( \bar{\nu}_M \) is:

\[
S(T_u(A), \bar{\nu}_M) = \{(N, r) \mid r \in S(A, \nu_M), \ r \geq N\delta\}.
\]

Since \( S(A, \nu_M) \) is finitely generated as a semigroup, generated by the columns of \( M \), it follows that \( S(T_u(A)) \) is also finitely generated.

The algebra \( T_u(A) \) has a natural vector space basis

\[
\hat{B} = \{bt^{-N\delta} \mid b \in \mathbb{B}_s, s \geq N\delta\}.
\]

This basis is adapted to the valuations \( \bar{\nu}_M \) and \( \bar{\nu}_u \), for all \( u \in C \).

Note that by definition the valuation \( \bar{\nu}_M \) is homogeneous with respect to the \( \mathbb{Z}_{\geq 0} \)-grading on \( T_u(A) \). Hence we can consider the Newton-Okounkov body \( \Delta_{u,\delta} = \Delta(T_u(A), \bar{\nu}_M) \).

By (7.2) we have:

\[
\Delta_{u,\delta} = \{r \in \mathbb{R}_{\leq 0} \mid r \geq \delta\} \cap P(A, \nu_M),
\]

where \( P(A, \nu_M) \) is the Newton-Okounkov cone of \((A, \nu_M)\), that is, the cone generated by the columns of the matrix \( M \).
Remark 7.5. (Toric degeneration of $\bar{X}_{u,\delta}$) When $r = d$, the associated graded algebra of the valuation $\bar{v}_M$ is isomorphic to the semigroup algebra $k[S(T_{u,\delta}(A), \bar{v}_M)]$. Moreover, for any $u \in C$, the associated graded algebra of $\bar{u}_u$ is also isomorphic to this semigroup algebra. It follows that we have a toric degeneration of $\bar{X}_{u,\delta}$ to the projective toric variety $\text{Proj}(k[S(T_{u,\delta}(A), \bar{v}_M)])$. The normalization of this toric variety is the toric variety associated to the polytope $\Delta_{u,\delta}$.

For the remainder of this section, we assume that $r = d$. In this case, we construct an embedding of $X$ into a projective toric variety $Y_{u,\delta}$ such that $\bar{X}_{u,\delta}$ is the closure of $X$ in $Y_{u,\delta}$.

Let us define the semigroup:

$$\bar{S}_\delta = \{(N, a) \mid N \in \mathbb{Z}_{\geq 0}, a \in \mathbb{Z}^n, Ma \geq N\delta\} \subset \mathbb{Z}_{\geq 0} \times \mathbb{Z}^n.$$  

Recall that if $a = (a_1, \ldots, a_n)$ then $Ma = \sum_{i} a_i v_M(b_i)$ and as before $\geq$ denotes the partial order on $\mathbb{Z}^n$ given by componentwise comparison of vectors. Note that from definition, $\bar{S}_\delta$ is a saturated semigroup.

Let $Y_{u,\delta} = \text{Proj}(k[\bar{S}_\delta])$ with respect to the grading by $N$. It is the projective toric variety associated to the polytope $\Delta_{u,\delta}$.

In other words, $\Delta_{u,\delta}$ is the polytope defined by the inequalities $a \leq 0$ and $a \cdot u_i \geq \delta_i$ for all $i = 1, \ldots, r$. Note that 0 is a vertex of the polytope $\Delta_{u,\delta}$ and the cone at this vertex is the negative orthant. Thus we can consider the toric variety $Y_{u,\delta}$ as a compactification of the affine space $\mathbb{A}^n$.

There is a natural homomorphism $\bar{\pi} : k[\bar{S}_\delta] \to T_{u,\delta}(A)$ which sends $(N, a)$ to $((\prod_i b_i^{\pi_i}) t^{N\delta})$, where $a = (a_1, \ldots, a_n)$. One verifies that $\bar{\pi}$ is indeed surjective. We have the following proposition. We omit the straightforward proof.

Proposition 7.6. The scheme $Y_{u,\delta}$ is the normal projective toric variety associated to $\Delta_{u,\delta}$, and is a compactification of $\mathbb{A}^n$. Furthermore, the closure of $X \subset \mathbb{A}^n \subset Y_{u,\delta}$ is $\bar{X}_{u,\delta}$.

7.3. The divisor at infinity $D_{u,\delta}$. We let $D_{u,\delta}$ be the divisor in $\bar{X}_{u,\delta}$ defined by the ideal $I_u = (t^\delta) \cap T_{u,\delta}(A)$. (Here the ideal generated by $t^\delta$ means with respect to the $k[t]$-module structure on the Rees algebra $R_{u,\delta}(A)$ given by map $\phi$ in Section 7.1 after the definition of $R_{u,\delta}(A)$.)

To simplify the discussion, we assume that $\delta = (-1, \ldots, -1)$. Let us see that this is always possible. Since $\delta$ is in the relative interior of $P(A, v_M)$ we can find $v \in \mathbb{Q}_{\geq 0}^r$ such that $Mv = -\eta$. Now let $u'_i = \frac{\eta_i \cdot \eta_{\delta_i}}{\eta_{\delta_i}} u_i$ and $v' = \frac{v}{\eta_{\delta_i}}$. Now if $M'$ is the matrix whose rows are the $u'_i$, it easy to check that $M'v' = (-1, \ldots, -1)$.

Under the assumption $\delta = (-1, \ldots, -1)$, we have that $D_{u,\delta}$ is the divisor at infinity $\bar{X}_{u,\delta} \setminus X$. The purpose of this section is to show that:

1. The divisor $D_{u,\delta}$ has combinatorial normal crossings.
2. The vectors $u_i \in u$ are in one-to-one correspondence with the irreducible components of $D_{u,\delta}$, and moreover, for every $u_i \in u$, the valuation $v_{u_i}$ is given by the order of vanishing along the corresponding irreducible component of $D_{u,\delta}$.

Before we proceed with the proofs, we need few more definitions. Let $\sigma \subset u = \{u_1, \ldots, u_r\}$. To $\sigma$ we associate the ideal $I_\sigma \subset T_{u,\delta}(A)$ defined by:

$$I_\sigma = \langle t_i \mid u_i \in \sigma \rangle \cap T_{u,\delta}(A).$$
We note that since for every \(i\), \(\langle t_i \mid u_i \in \mathfrak u \rangle \subset A[t]\) is a prime ideal, the ideal \(I_\sigma \subset T_{u, \delta}(A)\) is also prime. In particular, for every \(i\), we let \(I_i = \langle t_i \rangle \cap T_{u, \delta}(A)\) and we denote by \(D_i\) the divisor in \(X_{u, \delta}\) defined by the ideal \(I_i\).

**Proposition 7.7.** \(D_{u, \delta} = \sum_i D_i\) is a divisor in \(X_{u, \delta}\) with combinatorial normal crossings.

**Proof.** It is straightforward to check that the ideals \(I_\sigma = \langle t_i \mid \sigma \in \sigma \rangle \cap T_{u, \delta}(A)\) are distinct and prime. Thus it suffices to show that the subscheme in \(X_{u, \delta}\) defined by the largest ideal \(I_u\) has the correct codimension equal to \(r\). The subscheme in \(E_u = \text{Spec}(R_u(A))\) defined by the ideal \(\langle t_i \mid i = 1, \ldots, r\rangle\) is the fiber \(\pi^{-1}(0)\) over 0 of the family \(\pi : E_u \to \mathbb A^r\).

By Proposition 7.2, the fiber \(\pi^{-1}(0)\) is isomorphic to \(\text{Spec}(\text{gr}_{\mathfrak v_M}(A)\) of the valuation \(\mathfrak v_M\).

We also know that the cone generated by the \(\mathbb G_m^r\)-weights of the algebra \(\text{gr}_{\mathfrak v_M}(A)\) is the Newton-Okounkov cone \(P(A, \mathfrak v_M)\). This cone has dimension \(r = \text{rank}(M)\) which is equal to the dimension of the prime cone \(C\) we started with. Now since the fiber \(\pi^{-1}(0)\) is stable under the \(\mathbb G_m^r\)-action on \(E_u\), we conclude that the subscheme in \(X_{u, \delta}\) defined by \(I_u\) is isomorphic to the GIT quotient \(\pi^{-1}(0)/\langle \mathbb G_m^r \rangle\). The claim now follows form the following lemma from geometric invariant theory. For completeness, we include sketch of a proof.

**Lemma 7.8.** Let \(R\) be a finitely generated algebra with Krull dimension \(d\) and equipped with a rational \(\mathbb G_m^r\)-action where \(r \leq d\). Suppose the cone \(C(R) \subset \mathbb Q^r\) generated by the weights of the \(\mathbb G_m^r\)-action has maximal dimension \(r\). Let \(\delta\) be a weight which lies in the interior of \(C(R)\). Then the GIT quotient \(\text{Spec}(R)/\langle \mathbb G_m^r \rangle\) has dimension \(d - r\).

**Proof.** It suffices to show that the action of \(\mathbb G_m^r\) on \(\text{Spec}(R)\) has a stable point. After shifting by \(-\delta\) we can assume without loss of generality that \(\delta = 0\). Let \(h_i \in R, i = 1, \ldots, s\), be weight vectors which generate \(R\) as an algebra. For each \(i\), let \(\lambda_i\) denote the weight of \(h_i\).

The choice of the algebra generators \(h_i\) gives a \(\mathbb G_m^r\)-equivariant embedding of \(\text{Spec}(R)\) into the affine space \(\mathbb A^s\). Since the cone generated by the \(\lambda_i\) is \(r\)-dimensional we conclude that the generic \(\mathbb G_m^r\)-stabilizer is finite. Also, by assumption, \(\delta = 0\) is an interior point of the cone generated by the \(\lambda_i\). It follows that all the \(\mathbb G_m^r\)-orbits in \(\mathbb A^s\) are closed. Finally, since all the \(h_i\) are nonzero, the image of \(\text{Spec}(R)\) intersects the open subset \(\mathbb G_m^s \subset \mathbb A^s\). This shows that the set of stable points in \(\text{Spec}(R)\) is nonempty. \(\square\)

**Corollary 7.9.** For every \(u_i \in \mathfrak u\) the valuation \(\mathfrak v_{u_i}\) is given by the order of vanishing along the divisor \(D_i\). That is, for any \(0 \neq f \in A\) the value \(\mathfrak v_{u_i}(f)\) is equal to order of zero/pole of \(f\) along the divisor \(D_i\).

**Proof.** Let \(\chi\) be a character of \(\mathbb G_m^r\) of weight \(-\delta\), so that \(T_{u, \delta} = [R_u(A) \otimes k[\chi]]^{\mathbb G_m^r}\). The ideal \(\langle t_i \rangle \subset R_u(A) \otimes k[\chi]\) is \(\mathbb G_m^r\)-stable and the unique maximal ideal at this ideal can be generated by the invariant \(t_1 \cdots t_r \chi\) for all \(i\). As a consequence it generates the maximal ideal in the local ring at \(I_i \subset T_{u, \delta}(A)\), and it follows that the \(D_i\) degree of any regular function \(f \in A\) on \(X\) can be computed by taking the \(t_i\)-degree, as \(f = \frac{\bar{f}}{\prod_{j} \bar{v}_{u_j}(f)} \in A \subset t_1 \cdots t_r R_u(A)\) for \(\bar{f} = f \prod_j \bar{v}_{u_j}(f) \in R_u(A)\). We obtain that this degree is \(\mathfrak v_{u_i}(f)\). \(\square\)

8. Examples

**Example 8.1** (The wonderful compactification of an adjoint group \(G\)). Let \(G\) be an adjoint form of a simple algebraic group. We show that the wonderful compactification \(\mathcal G\) can be realized by means of the compactification construction outlined in Section 7.2.
We pick a system of simple roots \( \alpha_1, \ldots, \alpha_r \), these generate the root lattice \( \mathcal{R} \). Let \( h_1, \ldots, h_r \in \mathfrak{h} \) be the corresponding coroots; recall that these pair with the weights \( \Lambda \) such that \( \omega_i(h_j) = \delta_{ij} \) for the fundamental weights \( \omega_i \). The \( \omega_1, \ldots, \omega_r \) generate the monoid of dominant weights \( \Lambda_+ \subset \Lambda \). Finally, let \( \hat{\alpha}_1, \ldots, \hat{\alpha}_r \) be the fundamental coweights; these have the property that \( \alpha_j(\hat{\alpha}_i) = \delta_{ij} \). In particular if \( \omega < \eta \) in the dominant weight ordering, we must have \( (\eta - \omega)(\hat{\alpha}_i) \geq 0 \) for each \( 1 \leq i \leq r \).

The coordinate ring \( k[G] \) is known to have the following direct sum decomposition:

\[
(8.1) \quad k[G] = \bigoplus_{\lambda \in \Lambda_+} \text{End}(V(\lambda)).
\]

Here \( V(\lambda) \) is the irreducible representation of \( G \) associated to \( \lambda \in \Lambda_+ \). Each fundamental coweight defines a rank 1 \( (G \times G) \)-invariant valuation \( v_i : k[G] \setminus \{0\} \to \mathbb{Z} \), where the filtration defined by \( v_i \) is by the subspaces \( F_{\leq m} = \bigoplus_{\eta(\hat{\alpha}_i) \leq m} \text{End}(V(\eta)) \subset k[G] \). Let \( R(G) \) denote the Rees algebra associated to the \( v_i \):

\[
(8.2) \quad R(G) = \bigoplus_{r \in \mathbb{Z}_{\geq 0}} \bigoplus_{\lambda(\hat{\alpha}_i) \leq r} \text{End}(V(\lambda))t^r.
\]

**Remark 8.2.** This Rees algebra has been considered by Popov [Pop87] in the context of the horospherical contraction of a \( G \) variety.

We select a weight \( \rho \) with the property that \( \rho(h_i) > 0 \), and we let \( \delta = (\rho(\hat{\alpha}_1), \ldots, \rho(\hat{\alpha}_r)) \).

Finally, we define \( T_\delta(G) \) as in Section 7.2:

\[
(8.3) \quad T_\delta(G) = \bigoplus_N \bigoplus_{\lambda(\hat{\alpha}) \leq N\delta} \text{End}(V(\lambda))t^N.
\]

There is an ample \( (G \times G) \)-line bundle \( L_\rho \) on the wonderful compactification \( \overline{G} \) corresponding to \( \rho \). Global sections of \( L_\rho \) have the following description:

\[
(8.4) \quad H^0(\overline{G}, L_\rho^\otimes N) = \bigoplus_{\lambda \prec N\rho} \text{End}(V(\lambda)).
\]

We claim that \( H^0(\overline{G}, L_\rho^\otimes N) = \bigoplus_{\lambda(\hat{\alpha}) \leq N\delta} \text{End}(V(\lambda))t^N \). For \( \lambda < N\rho \) we must have \( N\rho - \lambda = \sum n_i \alpha_i \) for \( n_i \in \mathbb{Z}_{\geq 0} \); it follows that \( H^0(\overline{G}, L_\rho^\otimes N) \subset \bigoplus_{\lambda(\hat{\alpha}_i) \leq N\delta} \text{End}(V(\lambda))t^N \).

For the other inclusion, suppose more generally that \( (\eta - \lambda)(\hat{\alpha}_i) \geq 0 \) for all \( i \). The group \( G \) is adjoint and hence \( \mathcal{R} = \Lambda \), so it follows that \( \eta - \lambda = \sum n_i \alpha_i \) for \( n_i \in \mathbb{Z} \). If any of these coefficients were negative, the corresponding \( \hat{\alpha}_i \) would likewise evaluate to a negative integer. Consequently, we must have \( \overline{G} = \text{Proj}(T_\delta(G)) \).

**Example 8.3** (Gel’fand-Zetlin patterns and the Plücker algebra). Let \( k \subset F \) be a transcendental field extension, and \( v : F \setminus \{0\} \to \mathbb{Z}^d \) a valuation of rank equal to the transcendence degree of \( F \) over \( k \). It is natural to ask when a finite subset \( \mathcal{B} \subset F \) is a Khovanskii basis for the \( k \)-algebra \( k[B] \subset F \) generated by \( B \), with respect to \( v \). Let \( \mathcal{X} \) be an \( n \times n \) array of indeterminates \( x_{ij} \), and let \( k[\mathcal{X}] \) be the quotient field of the polynomial algebra \( k[\mathcal{X}] \). A rank \( n^2 \) valuation \( v \) can be defined on \( k[\mathcal{X}] \) by ordering the monomials in \( k[\mathcal{X}] \) lexicographically using the row-wise ordering of the entries of \( \mathcal{X} \):

\[
(8.5) \quad x_{11} > \ldots > x_{1n} > x_{21} > \ldots > x_{2n} > \ldots > x_{nn}.
\]
Let $\sigma \subset \{1, \ldots, n\}$ be an ordered subset, and let $p_{\sigma} \in k(x)$ be the form obtained by taking the determinant of the $|\sigma| \times |\sigma|$ minor of $X_{\sigma}$ composed of the $x_{ij}$ with $1 \leq i \leq |\sigma|$ and $j \in \sigma$. The algebra $k[P] \subset k(x)$ is known as the Plücker algebra. It is the coordinate ring of the quotient variety $GL_n(k)/U$, where $U \subset GL_n(k)$ is the unipotent group of upper triangular matrices with 1’s on the diagonal, and also it can be identified with the total coordinate ring of the full flag variety $\mathcal{F}_{n}$.

The valuation $\nu$ induces a maximal rank valuation on $k[P]$ with Khovanskii basis $P$, see [MS05, Theorem 14.11]. It is also known (see e.g. [MS05, Theorem 14.23]) that the associated graded algebra $\text{gr}_\nu(k[P])$ is isomorphic to affine semigroup algebra of the Gel’fand-Zetlin pattern semigroup $GZ_n \subset \mathbb{Z}_{\geq 0}^{\binom{n+1}{2}}$. An element $w \in GZ_n$ is a tringular array of $\binom{n+1}{2}$ non-negative integers $w_{i,j}$ $1 \leq i \leq n$, $1 \leq j \leq n+1-i$, organized into $n$ rows of lengths $n, n-1, \ldots, 1$. These entries satisfy the inequalities $w_{i,j} \geq w_{i-1,j} \geq w_{i,j-1}$.

The ideal $I$ of polynomial relations among the $p_{\sigma}$ is generated by a set of quadratic polynomials $G$ which is best described combinatorially; we follow the presentation in [MS05, Theorem 14.6]. There is a partial order on the $\sigma \subset \{1, \ldots, n\}$, where $\sigma \prec \tau$ if $|\sigma| \leq |\tau|$ and $\sigma_i \leq \tau_i$ for all $1 \leq i \leq |\sigma|$ (here $\sigma_i$ and $\tau_i$ denote the $i$-th elements in increasing order in $\sigma$ and $\tau$ respectively). If $\sigma$ and $\tau$ are incomparable with respect to $\succ$ and $s = |\sigma| \geq |\tau| = t$ there is some index $j$ with $\sigma_j > \tau_j$. Let $g_{\sigma,\tau}$ be the following polynomial, where the sum is taken over all permutations $S_{\sigma,\tau}$ of the $s+1$ indices $\tau_1, \ldots, \tau_j, \sigma_j, \ldots, \sigma_s$:

\begin{equation}
\sum_{\pi \in S_{\sigma,\tau}} \text{sign}(\pi)p_{\pi(\sigma)}p_{\pi(\tau)}.
\end{equation}

The set $G$ is composed of all $g_{\sigma,\tau}$, where $\sigma$ and $\tau$ are incomparable. The partial order $\succ$ defines a lattice on the $\sigma$, let $\wedge$ and $\vee$ be the meet and join in this lattice. The initial ideal $\text{in}_\nu(I)$ is generated by the binomial initial forms of the members of $G$:

\begin{equation}
p_{\sigma}p_{\tau} - p_{\sigma \wedge \tau}p_{\sigma \vee \tau}.
\end{equation}

The valuation $\nu$ induces a partial ordering on the monomials in the variables $P$, this partial ordering can be completed to a monomial ordering by first ordering with $\nu$ and then ordering with the reverse lexicographic ordering induced by the total ordering on the $\sigma$ where $\sigma \prec \tau$ if $|\sigma| > |\tau|$ or $|\sigma| = |\tau|$ and $\sigma$ comes before $\tau$ in the lexicographic ordering on subsets of $\{1, \ldots, n\}$. We call this concatenated ordering $\succ$. We have made this choice so that [MS05, Theorem 14.16] implies that $G$ is a Gröbner basis with respect to $\succ$, and $\text{in}_\nu(\text{in}_\nu(g_{\sigma,\tau})) = \text{in}_\nu(g_{\sigma,\tau}) = p_{\sigma}p_{\tau}$ for each $g_{\sigma,\tau} \in G$. Proposition 8.2 then implies the following.

**Proposition 8.4.** Let $C_{GZ}$ be the cone of weights $u \in \mathbb{Q}^{2^n-1}$ in the Gröbner fan of $I$ defined by the following inequalities:

\begin{equation}
\text{in}_u(g_{\sigma,\tau}) = p_{\sigma}p_{\tau} - p_{\sigma \wedge \tau}p_{\sigma \vee \tau},
\end{equation}

\begin{equation}
u_{\sigma} + \nu_{\tau} = \nu_{\sigma \wedge \tau} + \nu_{\sigma \vee \tau} \geq \nu_{\pi(\sigma)} + \nu_{\pi(\tau)}, \quad \pi \in S_{\sigma,\tau}.
\end{equation}

For any $u \in C_{GZ}^\circ$, $\text{in}_u(I) = \text{in}_\nu(I)$, so $C_{GZ}$ is a prime cone in the tropical variety of $I$. 38
By Proposition 6.5, the \( \mathbb{Z}_{\geq 0} \) column span of any matrix \( M_{\text{GZ}} \) with rank equal to the dimension of \( k[P] \) and rows taken from \( C_{\text{GZ}} \) is isomorphic to the Gel’fand-Zetlin patterns as a semigroup.

**Example 8.5** (\( \text{Gr}_3(\mathbb{C}^6) \)). We show that Algorithm 2.17 can find a Khovanskii basis of the \( \text{Gr}_3(\mathbb{C}^6) \) Plücker algebra for a valuation defined in \[\text{Man16}\] using the Plücker generators as input.

In \[\text{Man16}\], the second author defines a family of maximal rank valuations on the coordinate ring \( \mathbb{C}[P_n(\text{SL}_3(\mathbb{C}))] \) of the configuration space \( P_n(\text{SL}_3(\mathbb{C})) = \text{SL}_3(\mathbb{C}) \backslash [\text{SL}_3(\mathbb{C})/U]^n \).

Here the right quotients are by \( U \subset \text{SL}_3(\mathbb{C}) \), a maximal unipotent subgroup, and the left quotient is the Geometric Invariant Theory quotient by the diagonal action of \( \text{SL}_3(\mathbb{C}) \). The projective coordinate ring \( \mathbb{C}[\text{Gr}_3(\mathbb{C}^n)] \) of the Grassmannian variety of 3-planes in \( \mathbb{C}^n \) with respect to its Plücker embedding is naturally realized as a subalgebra of \( \mathbb{C}[P_n(\text{SL}_3(\mathbb{C}))] \), and therefore inherits these maximal rank valuations.

For a particular selection of combinatorial parameters, the value semigroup of one of these valuations \( v : \mathbb{C}[\text{Gr}_3(\mathbb{C}^6)] \to \mathbb{Z}^{36} \) is a sub-semigroup \( B_{\text{GZ}}(3,6) \) of the Berenstein-Zelevinsky quivilts for a particular choice of trivalent 6-leaf tree \( T \). This semigroup is studied in \[\text{MZ14}\], and examples of members of this semigroup are depicted in Figure 6.

By \[\text{MZ14}\], \( B_{\text{GZ}}(3,6) \) is generated by the images \( v(p_{ijk}) \) of the \( \binom{n}{3} \) Plücker coordinate functions, and the image \( v(T) \) of one additional coordinate function \( T \). Furthermore, it can be shown that the image of \( T \) (in the associated graded) is not expressible as a monomial in the images of the Plücker generators. However, \( T \) itself can be written as a binomial in the Plücker generators:

\[
(8.10) \quad T = p_{135}p_{246} - p_{235}p_{146}.
\]

It can be shown that the following equation holds in the value semigroup \( B_{\text{GZ}}(3,6) \):

\[
(8.11) \quad v(p_{135}) + v(p_{246}) = v(p_{235}) + v(p_{146}).
\]

It follows that \( T \), and therefore a Khovanskii basis for \( \mathbb{C}[\text{Gr}_3(\mathbb{C}^6)] \) with respect to \( v \), can be found with one application of Algorithm 2.17 acting on the Plücker generators.

**Example 8.6** (The trace algebra on two letters). The set of representations \( \mathcal{X}(F_2, \text{SL}_2(\mathbb{C})) \) of the rank 2 free group \( F_2 \) into the complex group \( \text{SL}_2(\mathbb{C}) \) can be given the structure of an irreducible complex variety. This variety can be constructed as the image of \( \text{SL}_2(\mathbb{C}) \times \text{SL}_2(\mathbb{C}) \) under the polynomial map which sends a pair \((M, N) \in \text{SL}_2(\mathbb{C}) \times \text{SL}_2(\mathbb{C}) \) to the 3-tuple of traces \( t_1 = \text{tr}(M), t_2 = \text{tr}(N), x_1 = \text{tr}(MN) \); this identifies \( \mathcal{X}(F_2, \text{SL}_2(\mathbb{C})) \) with \( \mathbb{C}^4 \), recovering the Fricke-Vogt Theorem. By incorporating an additional trace parameter \( x_2 = \text{tr}(MN^{-1}) \), \( \mathcal{X}(F_2, \text{SL}_2(\mathbb{C})) \) can be identified with the hypersurface of solutions to \( x_1 + x_2 - t_1t_2 = 0 \) in \( \mathbb{C}^4 \).

The tropical variety \( \mathcal{T} \subset \mathbb{Q}^4 \) of this hypersurface has a 2 dimensional lineality space \( L \) spanned by the vectors \((-1,-1,0,-1)\) and \((-1,-1,1,0)\). There are three maximal cones of \( \mathcal{T} \), each obtained by adding an additional vector to the lineality space:

\[
C_1 = \mathbb{Q}_{\geq 0}\{L, (-2,-2,0,0)\}, \quad \text{in}_{C_1}(x_1 + x_2 - t_1t_2) = x_1 + x_2,
\]

\[
C_2 = \mathbb{Q}_{\geq 0}\{L, (0,2,-1,-1)\}, \quad \text{in}_{C_2}(x_1 + x_2 - t_1t_2) = x_1 - t_1t_2,
\]

\[
C_3 = \mathbb{Q}_{\geq 0}\{L, (2,0,-1,-1)\}, \quad \text{in}_{C_3}(x_1 + x_2 - t_1t_2) = x_2 - t_1t_2.
\]
Notably, each of the resulting initial forms of $x_1 + x_2 - t_1 t_2$ is irreducible, it follows that $C_1, C_2, C_3$ are all prime cones. Taking for a moment the prime cone $C_1$, Theorem 4 implies that the weighting assigning $x_1, x_2, t_1, t_2$ the columns of the following matrix defines a rank 3 valuation $v_1 : \mathbb{C}[\mathcal{X}(F_2, \text{SL}_2(\mathbb{C}))] \to \mathbb{Z}^3$:

$$(8.12) \quad M_1 = \begin{bmatrix} -1 & -1 & -1 & 0 \\ -1 & -1 & 0 & -1 \\ -2 & -2 & 0 & 0 \end{bmatrix}$$

In [Man16], the second author describes a construction of a maximal rank valuation on the representation space $\mathcal{X}(F_g, G)$ for a free group of arbitrary rank and $G$ any connected complex reductive group. For the $g = 2, G = \text{SL}_2(\mathbb{C})$ case, the necessary input of this construction is a trivalent graph $\Gamma$ with first Betti number equal to 2, a choice of spanning tree in $\Gamma$, an orientation on the edges not in the chosen spanning tree, and a total ordering on the edges of $\Gamma$, see Figure 4. The valuation $v_1$ is constructed in [Man16] as the maximal rank valuation associated to the leftmost graph in Figure 4 in particular each row corresponds to an edge in this graph, and the total ordering on edges can be interpreted as a total ordering on rows of $M_1$ (inducing a lexicographic ordering on standard monomials). Matrices $M_2$ and $M_3$ can be constructed similarly for the cones $C_2$ and $C_3$, producing valuations $v_2$ and $v_3$; these valuations were constructed in [Man16] in association with the middle and rightmost graphs in Figure 4.

Notice that the non-spanning tree edges in each graph in Figure 4 have been labeled with $M$ or $N$. Each word $M, N, MN, MN^{-1}$ then corresponds to a unique closed cellular path through one of these graphs. The valuation $v_1$ can then be derived by reading off the number of times each of these paths crosses an edge (see [Man] for this construction). Taking for example the leftmost graph, the word $MN^{-1}$ crosses the left loop 1 time, the right loop 1 time, and the middle edge 2 times yielding the vector $(1, 1, 2)$; this is the negative of the first column of $M_1$. With the chosen orientation, the leftmost graph should not be able to distinguish between $MN$ and $MN^{-1}$, and indeed the second column of $M_1$ agrees with
the first column. In this way, the Newton-Okounkov polyhedra constructed in \cite{Man16} for $\mathcal{X}(\mathbb{P}_2, \text{SL}_2(\mathbb{C}))$ can be reproduced using the tropical variety $\mathcal{T}$ and the matrices $M_i$.
