Synchronous dual malignancy of papillary carcinoma thyroid and squamous cell carcinoma tongue: A case report

Tej Prakash Soni, Sajal Goel, Lalit Mohan Sharma, Anil Kumar Gupta, Shantanu Sharma, Ravindra Gothwal

ABSTRACT

Introduction: Patients with thyroid carcinoma have increased risk for development of second malignancy either synchronous or metachronous. We are reporting a rare case of synchronous squamous cell carcinoma oral tongue and papillary thyroid carcinoma.

Case Report: A 60-year-old smoker male was presented with the complaints of non-healing ulcer (2x2 cm) at right anterolateral tongue since six months. Excision biopsy of tongue ulcer was reported as pT 0.8x0.8 cm, moderately differentiated squamous cell carcinoma. Wide local excision of tongue lesion with right modified neck dissection was done. Histopathology was reported as no residual primary tongue tumor seen, 1 out of 28 lymph nodes showed metastatic deposits of squamous cell carcinoma. Unexpectedly another one lymph node was positive of metastatic thyroid papillary carcinoma. Total thyroidectomy with central compartment neck dissection and left modified neck dissection was done. Histopathology was reported as pT 2x1 cm, papillary carcinoma right lobe of thyroid, 7 out of 32 lymph nodes showed metastatic papillary carcinoma thyroid. Although exact cause of second malignancy is unknown but field cancerization, genetic predisposition, history of prior radiation or chemotherapy, improved survival can be attributed for increased incidence of second cancer.

Conclusion: Double malignancies require multidisciplinary management approach.

INTRODUCTION

Double malignancy now comprises the sixth most common cancers and it makes 16% of all incident cancers [1]. Head and neck is a common site for synchronous
malignancy owing to field cancerization with use of tobacco but the co-existence of tongue and thyroid primaries are rare [1]. Incidental cervical lymph node metastasis from papillary thyroid carcinoma, detected in lymph node dissection done for separate head neck primary cancer is extremely rare. A case of synchronous papillary thyroid carcinoma and squamous cell carcinoma tongue is being reported with review of literature.

CASE REPORT

A 60-year-old smoker male was presented with the complaints of non-healing ulcer over right side tongue since six months. On examination there was an ulcer (1x1 cm) at right anterolateral tongue and palpable ipsilateral submandibular lymph node size 2x2 cm. Excision biopsy of tongue ulcer was reported as pT 0.8x0.8 cm, moderately differentiated squamous cell carcinoma, depth 0.5 mm, no lymphovascular or perineural invasion, cut margins free of tumor. Fine needle aspiration cytology (FNAC) from right cervical lymph node was reported as metastatic squamous cell carcinoma. Metastatic work-up was done.

All routine blood investigations, X-ray chest, ultrasonound-whole abdomen were within normal limits. Wide local excision of tongue lesion with right modified neck dissection was done. Histopathology was reported as no residual primary tongue tumor seen, 1 out of 28 lymph nodes showed metastatic deposits of squamous cell carcinoma with no perinodal spread (Figure 1), 3 nodes showed epithelioid granulomas reaction, 1 lymph node showed a focus of follicles filled with colloid and lined by ovoid cells with optically clear nuclei suggestive of metastatic thyroid papillary carcinoma (Figure 2). Computed tomography scan neck showed an enhancing nodular lesion in right lobe of thyroid with large ring calcification measuring 2.9x1.7x1.8 cm in size with surgical changes in overlying cutaneous and subcutaneous tissues of neck (Figure 3). Total thyroidectomy with central compartment neck dissection and left modified neck dissection was done. Histopathology was reported as pT 2x1 cm, papillary carcinoma right lobe of thyroid, 7 out of 32 lymph nodes showed metastatic papillary carcinoma thyroid, maximum nodal size 2 cm, no extracapsular extension or lymphovascular invasion. Finally, he was diagnosed as a case of synchronous carcinoma anterior tongue pT1pN1M0 (stage III) and papillary carcinoma thyroid pT2pN1bM0. Expert opinion was sought from physician to rule out active tuberculosis. He received adjuvant external beam radiation to face/neck region to dose of 60Gy in 30 fractions over six weeks duration. He tolerated the treatment well. Whole body I-131 scan showed residual functioning thyroid tissue in thyroid bed. He received single dose of 150 mCi of I-131 orally. He was started on tablet levothyroxine 100 μg once a day and tablet calcium 500 mg twice a day.

Figure 2: Lymph node metastasis by papillary carcinoma thyroid (H&E stain, x100).

Figure 3: Axial view of contrast enhanced computed tomography scan of neck showing an enhancing nodular lesion (size 2.9x1.7x1.8 cm) in right lobe of thyroid with large ring calcification.
DISCUSSION

Thyroid cancer is the fifth most common cancer in females and accounts for 1% of all cancers. Incidence of carcinoma thyroid has increased significantly in last two decades. Surveillance epidemiology and end results database also reveals a 2.4-fold rise in thyroid cancer incidence from 3.6 per 100,000 in 1973 to 8.7 per 100,000 in 2002 consisting primarily of papillary thyroid carcinoma [2]. Wide use and availability of ultrasound and other imaging techniques contributes at least partly of this rise in incidence of carcinoma thyroid. Papillary thyroid cancer is the most common type of thyroid cancer and represents about 75% of all thyroid malignancies. Cervical lymph node metastasis is common in papillary thyroid cancer (ranging from 15–65% cases) and it is associated with a significant probability for loco-regional recurrence [3]. Lymphatic metastasis from papillary thyroid cancer occurs to neck lateral nodal groups of levels II, III, IV and central (level VI) lymph nodes. Thyroid cancer patients have an increased risk of developing a second cancer as either synchronous or metachronous [4]. In a pooled analysis of primary carcinoma thyroid patients from 13 registries, Sandeep et al. [4] found a 30% increase in risk of second cancers including salivary gland, kidney, prostate, skin, breast, brain, myeloma, leukemia, and non-Hodgkin lymphoma. On another side primary head neck cancer patients also have increased incidence (2–3% per year) of development of second primary cancer [5]. Barnes [6] found 0.7% of patients with squamous of carcinoma cell carcinoma of the head and neck cancers had lymphatic metastasis of papillary thyroid carcinoma. Singh J et al. [7] also reported a similar case of synchronous double malignancy of thyroid carcinoma and tongue carcinoma.

The exact mechanism of double malignancy is unknown. The predisposing risk factors for dual malignancy include field cancerization, tobacco and alcohol, genetic predisposition (Li–Fraumeni syndrome and Beckwith–Weidemann syndrome, Cowden syndrome), history of prior external radiation, radioiodine ablation or chemotherapy, environmental risk factors and improved survival [8].

Field cancerization also promotes transformation of an existing precancerous lesion into a malignancy and causes multifocal and second cancer in individual sites. Carcinogen exposure creates multiple genetic abnormalities in the whole tissue region and explores development of many foci of malignant transformation.

Thyroid cancer is associated with genetic mutations and abnormalities in tumor suppressor genes and cell cycle proteins which activates development of second cancers. Mutation of CHEK2 protein and RET genes are associated with an increased risk of thyroid, breast, prostate, and colon cancers [9].

CONCLUSION

In conclusion, incidence of second cancer has increased substantially. For early detection of second primary malignancy in head neck region complete and thorough examination and investigations including contrast enhanced computed tomography scan and pan-endoscopy are warranted. Squamous cell carcinoma of oral cavity along with synchronous papillary thyroid carcinoma is a rare situation. In such cases of double malignancy, multidisciplinary management and team work is required with the consensus of surgical oncology, radiation oncology, pathology, nuclear medicine and radiology experts. Oral cancers require aggressive treatment on priority as thyroid carcinoma has excellent prognosis. Metastatic workup followed by wide excision of primary oral cancer, total thyroidectomy and neck node dissection is required for adequate staging, proper diagnosis and management.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.*

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.*

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.

* Terms and condition apply. Please see Edorium Journals website for more information.
