**I. INTRODUCTION**

Recent measurements from some type Ia Supernovae (SNe) at intermediate and high redshifts (Perlmutter et al. 1999, Riess et al. 1998) indicate that the bulk of energy in the Universe is repulsive and appears like a “quintessence” component, that is, an unknown form of dark energy (in addition to the ordinary CDM matter) probably of primordial origin (see Turner 2000 for a review). Together with the observations of CMB anisotropies (de Bernardis 2000), such results seem to provide an important piece of information connecting an early inflationary stage with the astronomical observations.

This state of affairs has stimulated the interest for more general models containing an extra component describing this dark energy, and simultaneously accounting for the present accelerated stage of the Universe. However, the absence of a convincing evidence on the nature of the dark component gave origin to an intense debate and mainly to theoretical speculations. A possible list of old and new candidates for “quintessence” now include:

(i) a decaying vacuum energy density, or a time varying \( \Lambda \)-term (Özer and Taha 1987, Freese at al. 1987, Chen and Wu 1990, Carvalho et al. 1992, Waga 1993; for reviews see Overduin and Cooperstoock 1998; Sahni and Starobinski 2000)

(ii) the so-called “X-matter”, an extra component simply characterized by an equation of state \( p_x = \omega \rho_x \), where \( \omega \geq -1 \) (Turner and White 1997, Chiba et al. 1997, Efstathiou 1999, Lima and Alcaniz 2000, Turner 2000, Alcaniz and Lima 2001), which describes, as a particular case, cosmologies with a constant \( \Lambda \)-term (ACDM models). Generically, the \( \omega \) parameter may be a function of the redshift (Cooray and Huterer 2000)

(iii) a rolling scalar field (Ratra and Peebles 1988, Caldwell et al. 1998, Wang et al. 2000).

Here we are interested in the first class of models.

The basic reason is the widespread belief that the early Universe evolved through a cascade of phase transitions, thereby yielding a vacuum energy density which at present is at least 118 orders of magnitude smaller than in the Planck time (Weinberg 1989). Such a discrepancy between theoretical expectation (from the modern microscopic theory of particles and gravity) and empirical observations constitutes a fundamental problem in the interface uniting astrophysics, particle physics and cosmology, which is often called “the cosmological constant problem” (Weinberg 1989; Jack NG 1992; Dolgov 1997). This puzzle inspired some authors (Lima and Maia 1994, Lima and Trodden 1996) to propose a class of phenomenological deflationary cosmologies driven by a decaying vacuum energy density where the present value, \( \Lambda_o = \Lambda(t_o) \), is a remnant of the primordial inflationary stage (from now on the subscript “o” denotes the present day quantities). The basic scenario has an interesting cosmological history that evolves in three stages. Initially, an unstable de Sitter configuration, with no matter and radiation is supported by the largest values of the vacuum energy density. This non-singular de Sitter state evolves to a quasi-FLRW vacuum-radiation-dominated phase, and, subsequently, the Universe changes continuously from vacuum-radiation to the present vacuum-dust dominated phase. The first stage harmonizes the scenario with the cosmological constant problem, while the transition to the second stage solves the horizon and other well-know problems in the same manner as in inflation. Finally, the Universe enters in the present vacuum-dust phase with a negative deceleration parameter as required by the SNe type Ia observations.

In this article, we focus our attention on this class of deflationary decaying vacuum models. The effective time dependent cosmological term is regarded as a second fluid component with energy density, \( \rho_v(t) = \Lambda(t)/(8\pi G) \), which transfers energy continuously to the material component. The main goal is to investigate the basic kinematic tests in the present vacuum-dust dominated phase, or equivalently, how the classical cosmological tests may constrain the physical parameters of such models. The paper is organized as follows: In section 2, we set up the basic equations for deflationary cosmologies driven by a decaying \( \Lambda(t) \)-term. In section 3, the expressions for classi-
cal cosmological tests are derived and compared with the conventional expressions without the $\Lambda$-term. Section 4 gives the conclusion of the main results, and, in the appendix A, the exact expression yielding the dimensionless radial coordinate as a function of the redshift is deduced.

II. DEFlationary $\Lambda(t)$ COSMOLOGY: BASIC EQUATIONS

We shall consider a class of spacetimes described by the general FRW line element ($c = 1$)

$$ds^2 = dt^2 - R^2(t) \left( \frac{dr^2}{1 - kr^2} + r^2 d\theta^2 + r^2 sin^2 \theta d\phi^2 \right),$$

where $R(t)$ is the scale factor, $k = 0, \pm 1$ is the curvature parameter of the spatial sections, and $r, \theta$ and $\phi$ are dimensionless comoving coordinates. In that background, the Einstein field equations (EFE) with a nonvacuum component plus a cosmological $\Lambda(t)$-term are:

$$8\pi G \rho + \Lambda(t) = 3 \frac{\dot{R}^2}{R^2} + 3 \frac{k}{R^2},$$

$$8\pi G p - \Lambda(t) = -2 \frac{\ddot{R}}{R} - \frac{\dot{R}^2}{R^2} - \frac{k}{R^2},$$

where an overdot means time derivative, $\rho$ and $p$ are the energy density and pressure, respectively. As usual, we consider that the nonvacuum component obeys the “$\gamma$-law” equation of state

$$p = (\gamma - 1) \rho,$$

where $\gamma \in [1, 2]$ specifies if the fluid component is radiation ($\gamma = \frac{4}{3}$) or dust ($\gamma = 1$).

Phenomenologically, we also assume that the effective $\Lambda(t)$-term is a variable dynamic degree of freedom so that in an expanding universe it relaxes to its present value according with the following ansatz (Lima and Trodden 1996)

$$\rho_v = \frac{\Lambda(t)}{8\pi G} = \beta \rho T \left( 1 + \frac{1 - \beta}{\beta} \frac{H}{H_I} \right),$$

where $\rho_v$ is the vacuum density, $\rho_T = \rho_o + \rho$ is the total energy density, $H = \dot{R}/R$ is the Hubble parameter, $H_I^{-1}$ is the arbitrary time scale characterizing the deflationary period, and $\beta \in [0, 1]$ is a dimensionless parameter of order unity.

It is worth noticing that for $H = H_I$, the above definition reduces to $\rho_v = \rho_T$ so that we have inflation with no matter-radiation component ($\rho = 0$). In particular, if $H_I^{-1}$ is the order of the Planck time, that is, $H_I^{-1} \sim 10^{-43}$, one may show that such models are in accordance with the cosmological constant problem in the sense that $\Lambda_{Planck}/\Lambda_o \sim 10^{118}$.

At late times ($H << H_I$), we see from (5) that $\rho_v \sim \beta \rho_T$, as required by the recent Supernovae observations. To be more precise, if the deflationary process begins at Planck time, the ratio $H_o/H_I \sim 10^{-60}$ while the remaining terms are of order unity. Indeed, even if deflation begins much later, say at $10^{-35}$, or even at $10^{-15}$ (the respective scales of grand and electroweak unification in the standard model), one obtains $H_o/H_I \sim 10^{-32}$ and $H_o/H_I \sim 10^{-32}$, respectively. This means that to a high degree of accuracy, the scale $H_I$ is unimportant during the vacuum-dust dominated phase. Therefore, since in this work we mainly interested in the classical cosmological tests, henceforth we consider only this limiting behavior with the material component described by a pressureless fluid ($\gamma = 1$).

Let us now consider the evolution of the scale factor. Combining equations (3)-(5) and taking the limit $H << H_I$, it is readily seen that the scale factor during the vacuum-dust phase obeys the slightly modified FRW equation

$$2R\ddot{R} + (1 - 3\beta)\dot{R}^2 + (1 - 3\beta)k = 0,$$

the first integral of which is

$$\dot{R}^2 = \frac{A}{R^{1-3\beta}} - k,$$

where the constant $A > 0$ in order that $\rho$ be positive definite in this phase (see Eq.(2)). By expressing the constant $A$ in terms of the present day parameters, it is straightforward to show that the above equation can be rewritten as

$$\left( \frac{\dot{R}}{R_o} \right)^2 = H_o^2 \left[ 1 - \left( \frac{\Omega_o}{\beta} \right) + \left( \frac{\Omega_o}{1 - \beta} \right) \left( \frac{R_o}{R} \right)^{1-3\beta} \right],$$

where $\Omega_o \equiv \frac{\rho_v}{\rho_T}|_{t=t_o}$ is the present value of the matter density parameter. For $\beta = 0$ the above equation reproduces the standard cold dark matter FRW result (Kolb and Turner 1990). Whereas for $\beta \neq 0$, it describes the influence of the decaying vacuum in the present phase.

Following standard lines we also define the deceleration parameter $q_o = -\frac{\ddot{R}R - \dot{R}^2}{R^2}$. Using equations (3) and (5) one may show that

$$q_o = \frac{1 - 3\beta}{2} \left( \frac{\Omega_o}{1 - \beta} \right).$$

Then, for any value of $\Omega_o \neq 0$, we see that the deceleration parameter $q_o$ with decaying vacuum energy is always smaller than the corresponding one of the FRW model. The critical case ($\beta = \frac{1}{3}, q_o = 0$), describes a “coasting cosmology”. However, instead of being supported by “K-matter” (Kolb 1989), this kind of model is obtained in the present context for a vacuum-dust filled universe, and the corresponding solutions hold regardless of the value
of $\Omega_\alpha$. It is also interesting that even negative values of $q_\alpha$ are allowed since the constraint $q_\alpha < 0$ can always be satisfied provided $\beta > 1/3$. These results are in line with recent measurements of the deceleration parameter $q_\alpha$ using Type Ia supernovae (Perlmutter et al. 1999; Riess et al. 1998). Such observations indicate that the universe may be accelerating today, which corresponds dynamically to a negative pressure term in the EFE. For a fixed $\Omega_\alpha$, this means that the universe with decaying vacuum is older than the corresponding FRW model with the usual deceleration parameter $q_\alpha \geq 0$. This behavior also reconcile other recent results (Freedman 1998), pointing to a Hubble parameter $H_\alpha$ larger than 50 km s$^{-1}$ Mpc$^{-1}$.

Now, combining equations (2), (5) and (7) for ($H \ll H_I$) one finds that vacuum and the matter energy density can be expressed as

$$\rho_v = \beta \rho_T = \beta \rho_{T0} \left( \frac{R_0}{R} \right)^{3(1-\beta)},$$

(10)

$$\rho = (1-\beta) \rho_T = (1-\beta) \rho_{T0} \left( \frac{R_0}{R} \right)^{3(1-\beta)},$$

(11)

where $\rho_{T0} = 3A/8\pi GR_0^3(1-\beta)$. In virtue of the decaying vacuum energy, we also see that the explicit dependence of the energy density on the scale factor $R(t)$ is slightly modified in comparison with the standard case. As should be expected from Eqs. (8) and (9), some dynamic expressions may be obtained from the standard FRW ones simply by replacing the “index” $\gamma$ = 1 by an effective parameter $\gamma_{eff} = 1 - \beta$ (see the above scale laws).

III. KINEMATIC TESTS

The kinematical relation distances must be confronted with the observations in order to put limits on the free parameters of the inflationary class of models presented in the last section. As remarked before, $H_\alpha$ cannot be constrained by the classical tests since it is unimportant in the present phase. It is adjusted in order to put the models in accordance to the cosmological constant problem (Lima and Trodden 1996). It thus follows that we have only the pair of free parameters ($\Omega_\alpha$, $\beta$) satisfying $\Omega_{T0} = \Omega_\alpha/(1-\beta)$, where $\Omega_{T0}$ is the present value of the total density parameter.

a) Lookback time-redshift diagram

The lookback time, $\Delta t = t_0 - t(z)$, is the difference between the age of the universe at the present time ($z = 0$) and the age of the universe when a particular light ray at redshift $z$ was emitted. By integrating (8) such a quantity is easily derived

$$t_0 - t(z) = H_\alpha^{-1} \int_0^z \frac{dx}{\sqrt{1 - \left( \frac{\Omega_\alpha}{1-\beta} \right) + \left( \frac{\Omega_\alpha}{1-\beta} \right) x^{-(1-3\beta)}}}.$$  

(12)

For $\beta = 0$ the above expressions reduce to the ones of the standard FRW models (Kolb and Turner 1990). Generically, we see that decaying vacuum increases the dimensionless parameter $H_\alpha$, while preserving the over-all expanding FRW behavior. The lookback time curves as a function of the redshift for some selected values of $\Omega_\alpha$ and $\beta$ are displayed in Fig. 1. For completeness, in Fig. 2 we show the age of the Universe (in units of $H_\alpha$) as a function of $q_\alpha$ for some selected values of $\beta$.

b) Luminosity distance-redshift

The luminosity distance of a light source is defined as the ratio of the detected energy flux $L$, and the apparent luminosity, i.e., $d_L^2 = \frac{L}{4\pi l^2}$. In the homogeneous and isotropic FRW metric (1) it takes the form below (Sandage 1988)

$$d_L = R_\alpha r_1(z)(1+z),$$

(14)

where $r_1(z)$ is the radial coordinate distance of the object at light emission. Inserting $r_1(z)$ derived in the Appendix, it follows that

$$d_L = \left(1+z\right)\sin[\delta\sin^{-1}(\alpha_1) - \delta\sin^{-1}(\alpha_2)] \sqrt{H_\alpha\left(\frac{\Omega_0}{1-\beta} - 1\right)^{\frac{1}{2}}}.$$  

(15)
\[ H_0 d_L = z + 1 - \frac{3z}{2} \left( \frac{\Omega_o}{1 - \beta} \right) \left( 1 + \frac{z}{2} \right) + \ldots, \quad (17) \]

which depends explicitly on the \( \beta \) parameter. However, replacing \( \Omega_o \) from (9) we recover the usual FRW expansion for small redshifts, which depends only on the effective deceleration parameter \( q_o \) (Weinberg 1972). This is not a surprising result since expanding \( d_L(z) \) in terms of \( \Omega_o \), the “00” component of Einstein’s equations has implicitly been considered, while the expansion in terms of \( q_o \) comes only from the form of the FRW line element.

The luminosity distance as a function of the redshift for closed and open models with decaying vacuum energy is shown in Figures 3 and 4, respectively. As expected for all kinematic tests, different cosmological models have similar behavior at \( z << 1 \), and the greatest discrimination among them comes from observations at large redshifts. A more quantitative analysis based on the SNe observations will be presented elsewhere.

c) Angular size-redshift

Another important kinematic test is the angular size-redshift relation \( \theta(z) \). As widely known, the data concerning the angular-size are until nowadays somewhat controversial (see Buchalter et al. 1998 and references therein). Here we are interested in angular diameters of light sources described as rigid rods and not as isophotal diameters. These quantities are naturally different, because in an expanding world the surface brightness varies with the distance (Sandage 1988). The angular size of a light source of proper size \( D \) (assumed free of evolutionary effects) located at \( r = r_1(z) \) and observed at \( r = 0 \)
is
\[ \theta = \frac{D(1+z)}{R_o r_1(z)} . \]
(18)

Inserting the expression of \( r_1(z) \) given in the Appendix A it follows that
\[ \theta = \frac{D H_o \left( \frac{1}{1 - \beta} - 1 \right)^{1/2} (1+z)}{\sin[\delta \sin^{-1} \alpha_1 - \delta \sin^{-1} \alpha_2]} . \]
(19)

For small \( z \) one finds
\[ \theta = \frac{D H_o}{z} \left[ 1 + \frac{1}{2} \left( 3 + 3\beta - \frac{2}{1-\beta} \right) z + ... \right] . \]
(20)

Hence, decaying vacuum cosmologies as modeled here also requires an angular size decreasing as the inverse of the redshift for small \( z \). However, for a given value of \( \Omega_o \), the second order term is a function only of the \( \beta \) parameter. In terms of \( q_o \), inserting (9) into (20) it is readily obtained
\[ \theta = \frac{D H_o}{z} \left[ 1 + \frac{1}{2} \left( 3 + 3\beta q_o \right) z + ... \right] , \]
(21)

which is formally the same FRW result for small redshifts (Sandage 1988). At this limit only the effective deceleration parameter may be constrained from the data, or equivalently, at small redshifts one cannot extract the values of \( \Omega_o \) and \( \beta \) separately. The angular size-redshift diagram for closed and open models and selected values of the \( \beta \) parameter is displayed in Figures 5 and 6, respectively.

d) Number counts-redshift

The final kinematic test considered here is the galaxy number count per redshift interval. The number of galaxies in a comoving volume is equal to the number density of galaxies (per comoving volume) \( n_g \), times the comoving volume element \( dV_c \)
\[ dN_g(z) = n_g dV_c = \frac{n_g r_1^2 dr d\Omega}{\sqrt{1 - kr^2}} . \]
(22)

By using \( r_1(z) \) as derived in appendix, it follows that
For small redshifts the general expression for number-counts can be written as

\[
\frac{(H_o R_o)^3 dN_g}{n_g z^2 dz d\Omega} = \frac{\sin^2 \delta [\sin^{-1}(\alpha_1) - \sin^{-1}(\alpha_2)]}{(1 + z)^2 f(\Omega_0, \beta, z)},
\]

where \( f(\Omega_0, \beta, z) = \left( \frac{\Omega_0}{1 - \beta} - 1 \right) \left[ 1 - \frac{\Omega_0}{1 - \beta} + \frac{\Omega_0}{1 - \beta} (1 + z)^{1 - 3 \beta} \right] \).

For small redshifts

\[
\frac{(H_o R_o)^3 dN_g}{n_g z^2 dz d\Omega} = 1 - 2 \left[ \frac{(\Omega_c - 1 - 3 \beta)}{2} + 1 \right] z + \ldots .
\]

In Figures 7 and 8 we have displayed the number counts-redshift relations for flat, closed and open Universes for some selected values of \( \Omega_c \) and \( \beta \). It is worth mentioning the tendency of decaying vacuum models to have larger volumes per redshift interval than the standard FRW models with the same \( \Omega_c \). This feature is similar to the one found in “quintessence” and \( \Lambda \)CDM cosmologies and could be advantageous if the observational data indicate an excess count of high-redshift objects. The limits on the \( \beta \) parameter obtained from all kinematic tests are shown in Table 1.

At this point, it is also interesting to compare our results with previous studies of kinematic tests for \( \Lambda(t) \) cosmologies. Observable expressions for a large class of flat decaying vacuum models were discussed by Waga (1993). In his paper, the time varying cosmological term was defined by \( \Lambda = \alpha R^{-2} + \beta H^2 + \gamma \), where \( \alpha \), \( \beta \) and \( \gamma \) are arbitrary constants. Although rather different from the deflationary ansatz assumed here, we see that in the limit \( H \ll H_o \), our expression (5) reduces to \( \rho_c \sim \beta \rho_F \), or equivalently, \( \Lambda \sim \beta (3H^2 + 3kR^{-2}) \). Therefore, by considering only the flat case \((k = 0)\) and taking \( \alpha = \gamma = 0 \), the late stages of the deflationary cosmologies has exactly the same behavior of the models examined by Waga. Note also that our \( \beta \) parameter must be identified with 1/3 of that one appearing in his paper. More recently, some aspects involving the angular size, luminosity distance, and SNe type Ia observations in \( \Lambda(t) \) models were also investigated by Vishwakarma (2000, 2001). By generalizing earlier papers (Chen and Wu 1990, Carvalho et al. 1992), He considered the interesting ansatz \( \Lambda = n \Omega H^2 \), where \( n \) is a dimensionless constant and \( \Omega \) is the density parameter of the fluid component. Although proposed as a new cosmology, if we rewrite this \( \Lambda(t) \) in terms of the total energy density, this decaying law corresponds precisely to the late stages of the deflationary universes for \( 3 \beta \). A more quantitative analysis accounting for angular sizes, the existence of old high redshifts galaxies, and ages constraints from globular clusters in this framework will be discussed in a forthcoming communication. We also remark that models driven by a gravitational adiabatic matter creation process (Calvão et al. 1992, Lima and Alcaniz 1999, Alcaniz and Lima 1999) present some kinematic expressions, like the dimensionless radial coordinate, which are similar to the ones discussed here for \( \Lambda(t) \) cosmologies (see Appendix). In these models, the present day matter creation rate, \( \rho_c = 3n_e H_0 \approx 10^{-16} \) nucleons \( cm^{-3} yr^{-1} \), is also nearly the same rate transferred from the decaying vacuum to the fluid component. However, these two spacetimes are completely different from a physical viewpoint because the negative creation pressure of the former scenario cannot be interpreted as a genuine decaying vacuum component.

### IV. CONCLUSION

The recent observational evidences for an accelerated state of the present universe, obtained from distant SNe Ia (Perlmutter et al. 1999, Riess et al. 1998) gave a strong support to the search of alternative cosmologies. As demonstrated here, a variable \( \Lambda \)-term or a decaying vacuum energy density is also an ingredient accounting for this unexpected observational result. In the present paper we have analyzed all kinematic expressions for flat, closed, and open cosmologies when the decaying vacuum is a fraction of the total energy density. At the later stages of the evolution, the rather slight changes intro-

TABLE I: Limits to \( \beta \)

| Test                  | Open | Closed |
|-----------------------|------|--------|
| Luminosity distance-redshift | \( \beta \leq 0.83 \) | \( \beta \leq 0.58 \) |
| Angular size-redshift  | \( \beta \leq 0.69 \) | \( \beta \leq 0.56 \) |
| Number counts-redshift | \( \beta \leq 0.19 \) | \( \beta \leq 0.34 \) |
duced by $A(t)$, which is quantified by the $\beta$ parameter, provides a reasonable fit of several cosmological data. Kinematic tests like luminosity distance, angular diameter and number-counts versus redshift relations constrain perceptively the decaying vacuum (see table 1). For models characterized by the pair ($\Omega_o, \beta$), the age of the universe is always greater than the corresponding FRW model ($\beta = 0$), and even values bigger than $H_o^{-1}$ are allowed for all values of the curvature parameter.

APPENDIX A: DIMENSIONLESS RADIAL COORDINATE VERSUS REDSHIFT RELATION

Some observable quantities in the standard FRW model are easily determined expressing the radial dimensionless coordinate $r$ of a source light as a function of the redshift (Mattig 1958). In this appendix, we derive a similar equation to the decaying vacuum energy scenario discussed in this paper.

Now consider a typical galaxy located at $(r_1, \theta_1, \phi_1)$ emitting radiation to an observer at $(r, \theta, \phi)$. If the waves leave the source at time $t_1$ and reach the observer at time $t_0$, the null geodesic equation defining the light track yields

$$\int_{t_0}^{t_1} dt / R(t) = \int_{r_0}^{r_1} dr / \sqrt{1 - k r^2} = \sin^{-1} \sqrt{k r_1 / R} = I .$$  \hspace{1cm} (A1)

Since $t = t(R)$, changing variable to $x = R / R_o$ and using (8), the above result reads

$$I = \frac{1}{R_o H_o} \int_{1}^{\delta} \frac{dx}{x} \sqrt{1 - (\frac{\Omega_o}{1-\beta}) x - (\frac{\Omega_o}{1-\beta})^{-1}} x^{-1/(1-\beta)} .$$  \hspace{1cm} (A2)

This integral depends on the values of the $\Omega_o$ and $\beta$ parameters. For $\beta = \frac{1}{3}$ one finds the same results of the coasting cosmology (Kolb 1989). For $\beta$ different of $\frac{1}{3}$, we introduce a new auxiliary variable $y^2 = [1 - (\frac{1+(\beta^2)}{\Omega_o})] x^{(1-3\beta)}$, in terms of which the above equation becomes

$$\sin^{-1} \sqrt{kr_1} / \sqrt{R} = \frac{\delta}{R_o H_o (\frac{\Omega_o}{1-\beta})^{-1} - 1} \int_{\alpha_2}^{\alpha_1} dy / \sqrt{1 - y^2} ,$$  \hspace{1cm} (A3)

where $\delta = \frac{2}{(1-\beta)}$, $\alpha_1 = [1 - (\frac{\Omega_o}{1-\beta})]^{-1}$, and $\alpha_2 = \alpha_1 (1 + z) - \frac{\Omega_o}{1-\beta}$.

The right hand side of the above integral is the same appearing in (A.1) for $k = 1$. Hence, replacing in (A.3) the value of $k$ given by [3] and (7), it is readily seen that

$$r_1(z) = \frac{\sin [\delta \sin^{-1} \alpha_1 - \sin^{-1} \alpha_2]}{R_o H_o (\frac{\Omega_o}{1-\beta})^{-1} - 1} .$$ \hspace{1cm} (A4)

In particular, the limit for a flat universe ($\Omega_o = 1$) yields

$$r_1(z) = \frac{2}{(1 - 3\beta) R_o H_o (1 - (1 + z) - \frac{\Omega_o}{1-\beta})} ,$$ \hspace{1cm} (A5)

which could have been obtained directly from (A.2).

In terms of the deceleration parameter (A.4) may be rewritten as

$$r_1(z) = \frac{\sin [\delta \sin^{-1} \alpha_1 - \sin^{-1} \alpha_2]}{R_o H_o (\frac{\Omega_o}{1-\beta})^{-1} - 1} .$$ \hspace{1cm} (A6)

which in the limit $\beta \to 0$ reduces to the usual FRW result (Weinberg 1972)

$$r_1(z) = \frac{q_o z + (q_o - 1)(\sqrt{2 q_o z + 1} - 1)}{H_o R_o q_o z (1 + z)} .$$ \hspace{1cm} (A7)

Equation (A.4), or equivalently (A.6), plays a key role in the derivation of some astrophysical quantities discussed in this paper.
