Abstract

Introduction: There are limited screening tools for sarcopenia in patients undergoing hemodialysis. This study aimed to investigate the reliability and validity of the SARC-F (Strength, Assistance in walking, Rise from a chair, Climb stairs, and Falls) questionnaire as a screening tool for sarcopenia (defined by the Asian Working Group for Sarcopenia [AWGS2019]) in patients undergoing hemodialysis. Methods: This cross-sectional study enrolled 179 patients (mean age: 66.5 ± 12 years, 58% men) undergoing maintenance hemodialysis 3 times per week at a hemodialysis center in Japan. The SARC-F score, handgrip strength, usual gait speed, sit-to-stand test time, short physical performance battery (SPPB), and appendicular skeletal muscle mass were evaluated. The reliability and validity of the SARC-F were analyzed using receiver-operating characteristic curve (AUC), and sensitivity/specificity analyses. Results: There were 49 (27.4%) patients with sarcopenia. Patients with SARC-F ≥4 (59 patients, 33.0%) had poorer grip strength, lower SPPB score, and slower gait speed than those with SARC-F <4, while the skeletal muscle mass index did not differ significantly between the two groups. The sensitivity and specificity values of the SARC-F for identifying sarcopenia were 42.9% and 70.8%, respectively, while those for identifying severe sarcopenia were 66.7% and 72.3%, respectively. The AUCs of SARC-F were 0.57 for sarcopenia and 0.70 for severe sarcopenia. Discussion/Conclusion: The SARC-F alone is an inadequate screening tool for sarcopenia in patients undergoing hemodialysis. It should be used in combination with objective assessment measures, rather than as a first-step screening tool, to diagnose sarcopenia.

Introduction

Sarcopenia is defined as the loss of skeletal muscle mass, muscle strength, and physical ability associated with aging [1, 2]. Sarcopenia is associated with a risk of fractures, depression, cognitive impairment, frailty, impaired ability to perform activities of daily living, and mortality in community-dwelling older adults [3–8]. Furthermore, it has been noted that sarcopenia might be more severe in vulnerable populations, such as patients with end-stage renal disease [9]. In patients on hemodialysis, the prevalence of sarcopenia has been reported to be between 12.7% and 40.0% [10–13], and it has been associated with adverse events such as mortality [10, 13–15]. Therefore, early identification and intervention for sarcopenia could be essential for effective disease management in patients on hemodialysis.

Sarcopenia diagnosis requires detailed investigations into the muscle strength and quantity. However, in clinical practice, this is challenging due to several reasons, such as a lack of experts (e.g., physiotherapists) and measuring equipment in the dialysis units [16, 17]. Therefore, there is a need for a simple tool that can help nephrologists in screening patients for sarcopenia in the clinical settings.

Recently, the European Working Group on Sarcopenia (EWGSOP) and the Asian Working Group on Sarcopenia (AWGS) have revised the diagnostic algorithm and some of the diagnostic cutoff values for sarcopenia [2, 18]. These recommendations, published in the EWGSOP2 and AWGS2019 guidelines, suggest case finding to identify early-stage sarcopenia and screen for sarcopenia. The SARC-F (Strength, Assistance in walking, Rise from a chair, Climb stairs, and Falls) is a simple questionnaire that can be used as an initial screening tool for sarcopenia and for quickly assessing the physical function [19, 20]. The SARC-F also predicts hospitalization and mortality in community-dwelling older adults and those with cardiovascular disease [4, 21, 22]. Furthermore, the SARC-F has been reported to be highly accurate in identifying the risk of physical limitations in patients on hemodialysis [23]. Therefore, we similarly hypothesized that the SARC-F may be useful as a screening tool for sarcopenia.

However, it is unclear whether the SARC-F is useful in screening for sarcopenia (defined by the muscle strength, physical performance, and muscle mass) in patients on dialysis. Therefore, the aim of this study was to validate the availability of the SARC-F as a screening tool for sarcopenia and to investigate the sensitivity and specificity of the SARC-F for sarcopenia (as defined by the AWGS2019).

Methods

Study Design and Population

This cross-sectional study enrolled clinically stable outpatients who underwent hemodialysis between April 2018 and February 2019 at a single dialysis unit in Japan. A total of 313 outpatients were assessed for eligibility. We excluded patients from further analyses for the following reasons: hospitalization within 3 months before the study ($n = 25$); severe dementia ($n = 6$); refusal to participate in this study ($n = 35$); missing data on the SARC-F ($n = 24$); and missing data on the muscle mass, muscle strength, or physical performance ($n = 44$). Finally, 179 patients on hemodialysis were included (online supplementary Fig. S1, available at www.karger.com/doi/10.1159/000518810). All participants were on dialysis for at least 3 months and were able to provide written consent. This study was performed in accordance with the ethical principles of the Declaration of Helsinki and was approved by the institutional research ethics committee.

Patient Characteristics

Data on the demographic factors (age, sex, body mass index [BMI], and hemodialysis vintage), primary kidney disease (glomerulonephritis/cystic kidney disease, diabetes, hypertension, others, and unknown), comorbidities, and biochemical results were collected from the medical records updated during the weeks in which the patients participated in the study. A comorbidity index [24], which was developed for patients on dialysis, was used to quantify the comorbidities. It included the primary causes of end-stage renal disease, atherosclerotic heart disease, congestive heart failure, cerebrovascular accident/transient ischemic attack, peripheral vascular disease, dysrhythmia, other cardiovascular diseases, chronic obstructive pulmonary disease, gastrointestinal bleeding, liver disease, cancer, and diabetes. The geriatric nutritional risk index [25] was also calculated as an index of the nutritional condition based on the serum albumin level and BMI. A short, 10-item version of the Center for Epidemiological Studies Depression Screening Index was used to assess the symptoms of depression, which were defined by a score of $\geq 10$ [26]. The Mini-Mental State Examination (MMSE) was used to evaluate the cognitive function. Cognitive impairment was defined by a score less than the cutoff point of 24 [27]. The education levels of the patients were classified into “lower than high school” and “high school or higher.”

SARC-F Questionnaire

The patients were asked to complete the SARC-F questionnaire at the time of the physical function evaluation. The SARC-F is a self-administered questionnaire used to determine the level of difficulty experienced in 5 components comprising the strength, assistance in walking, rising from a chair, climbing stairs, and history of falls; a score of 0–2 points is assigned for each item (Table 1) [19]. The total score ranges from 0 to 10, with scores of $\geq 4$ points indicating the risk of sarcopenia.

Measurement of Muscle Strength

Muscle strength was assessed by the handgrip strength, which was measured using a digital dynamometer (TKK 5101 Grip-D; Takei, Tokyo, Japan) with the patients in the sitting position. Maximal isometric voluntary contractions of both hands were measured for 3 s each, with the elbow joint flexed at 90°. Handgrip
Assessment of the Physical Performance

Usual gait speed was measured during a 10-m timed walk. Patients were asked to walk the course at their usual pace and were timed at the middle of a 10- to 16-m walkway. To account for acceleration and deceleration, there was a 3-m distance before and after their assigned walking space. Usual gait speed was measured once and expressed in meters per second.

For the sit-to-stand test, a stopwatch was used to measure how long it took the participant to stand up from a sitting position and sit down again with the arms crossed in front of the chest, 5 times, as quickly as possible. The Short Physical Performance Battery (SPPB), which consists of the usual gait speed, repeated standing up from the chair, and standing balance, was measured according to the established methods [28]. The SPPB score ranged from 0 to 12 (0 = worst and 12 = best), with a scale of 0–4 points for each component.

Most patients underwent predialysis muscle strength and physical performance tests. However, those who could be assessed only after dialysis were evaluated when they were in a good physical condition.

Assessment of Muscle Mass

Muscle mass was assessed before a dialysis session by multifrequency whole-body BIA using InBody S10 (InBody Co., Ltd., Seoul, South Korea), which provided the total and segmental muscle mass through the arms and legs in kilograms. Patients were asked to remain in the sitting position for 10 min before the test to ensure body fluid balance. The appendicular skeletal muscle mass (ASM) was measured, and the skeletal muscle mass index (SMI) was calculated as ASM (kg)/height (m)^2.

Definition of Sarcopenia by the AWGS2019 Criteria

Sarcopenia was defined using the AWGS2019 criteria [2]. The cutoff values were as follows: low muscle mass was defined as SMI <7.0 kg/m^2 for men and <5.7 kg/m^2 for women; low muscle strength was defined as handgrip strength <28 kg for men and <18 kg for women; and low physical performance was defined as a gait speed <1.0 m/s, sit-to-stand time ≥12 s, and/or SPPB ≤9 for both sexes. According to the AWGS2019 criteria, sarcopenia was diagnosed if the patient had a low muscle mass and low muscle strength or low physical performance. Severe sarcopenia was defined as the presence of low muscle mass, low muscle strength, and low physical performance.

Statistical Analysis

Normally distributed continuous variables were expressed as means ± standard deviations, and nonnormally distributed continuous variables were presented as medians (interquartile ranges). Categorical variables were expressed as numbers and percentages. The patients were classified into two groups according to the SARC-F score: SARC-F <4 and SARC-F ≥4 [29]. Baseline patient characteristics and the prevalence of sarcopenia were compared between the two groups using the unpaired Student’s t test, Mann-Whitney U test, or χ^2 test, as appropriate. In addition, we evaluated the sensitivity, specificity, and positive and negative predictive values. The areas under the curves (AUCs) for the SARC-F scores, defined by the AWGS2019 diagnostic criteria, were computed, and receiver operating characteristic curve analysis was performed. Furthermore, the sensitivity, specificity, and positive and negative predictive values of each SARC-F score were calculated to investigate the screening accuracy of SARC-F for sarcopenia (as defined by the AWGS2019). The analyses were performed using Stata version 16.1 (Stata Corp LP, College Station, TX, USA). A two-tailed p value of <0.05 was considered to indicate statistical significance.

| Component     | Question                                      | Scoring                                      |
|---------------|-----------------------------------------------|----------------------------------------------|
| Strength      | How much difficulty do you have in lifting and carrying 10 lb? | None = 0, Some = 1, A lot or unable = 2 |
| Assistance in walking | How much difficulty do you have walking across a room?  | None = 0, Some = 1, A lot, use aids, or unable = 2 |
| Rise from a chair | How much difficulty do you have transferring from a chair or bed? | None = 0, Some = 1, A lot, or unable without help = 2 |
| Climb stairs | How much difficulty do you have climbing a flight of 10 stairs? | None = 0, Some = 1, A lot or unable = 2 |
| Falls | How many times have you fallen in the past year? | None = 0, 1–3 falls = 1, ≥4 falls = 2 |

Results

Patient Characteristics

Table 2 shows the characteristics of all participants and
the groups stratified by the SARC-F score. The mean
age of the study population was 66.5 ± 12 years. Furthermore,
58% of the patients were men, and the median hemodi-
alysis vintage was 6.0 years (interquartile range: 2.0–14.0
years). There were 59 (33.0%) and 120 (67%) patients in
the SARC-F ≥4 and SARC-F <4 groups, respectively. The
number of patients with sarcopenia according to the
AWGS2019 criteria was 49 (27.4%). Compared to the
SARC-F <4 group, the SARC-F ≥4 group had older pa-
tients, higher comorbidity scores, higher prevalence of
cognitive impairment, and greater number of patients
with a less than high school level of education. Further-
more, the SARC-F ≥4 group had a significantly lower
handgrip strength, slower usual gait speed, longer sit-to-
stand position time, lower SPPB score, and poorer physi-
cal performance as compared to the SARC-F <4 group (all
p < 0.001). In contrast, there was no significant difference
in the prevalence of low SMI between the two groups (Ta-
ble 3).

Validation of the SARC-F

The SARC-F and AWGS2019 criteria diagram is
shown in Figure 1. When assessed according to the
AWGS2019 criteria, the SARC-F ≥4 group comprised 5
and 16 patients with sarcopenia and severe sarcopenia,
respectively. In contrast, the SARC-F <4 group com-
prised 20 and 8 patients diagnosed with sarcopenia and
severe sarcopenia, respectively. These results showed that

| SPPB score                                          | 12.0 [10.0–12.0] | 12.0 [11.0–12.0] | 9.0 [6.0–11.0] | <0.001  |
| Skeletal muscle index, kg/m²                         | 6.9 (1.3)  | 7.0 (1.2)  | 6.6 (1.3)  | 0.047   |

Values are expressed as mean (standard deviation), n (%) of patients, or median [interquartile range]. BMI, body mass index; CHF, congestive heart failure; CVA/TIA, cerebrovascular accident/transient ischemic attack; GN, glomerulonephritis; GNRI, geriatric nutritional risk index; MMSE, Mini-Mental State Examination; SPPB, short physical performance battery. * Missing values on education level (n = 12).
in the SARC-F <4 group, as many as 28 (23.4%) patients had been overlooked.

The sensitivity, specificity, positive predictive values, and negative predictive values for the AWGS2019 criteria are shown in Table 4. SARC-F had a low to moderate sensitivity (42.9% for sarcopenia and 66.7% for severe sarcopenia), moderate specificity (70.8% for sarcopenia and 72.3% for severe sarcopenia), and relatively high negative predictive value (76.7% for sarcopenia and 93.3% for severe sarcopenia). The AUCs of SARC-F for sarcopenia and severe sarcopenia were 0.57 (95% confidence interval [CI]: 0.49–0.65) and 0.70 (95% CI: 0.59–0.80), respectively.

**Table 3. Comparison for the number of patients who met each criterion for sarcopenia**

|                  | Overall  | SARC-F <4 | SARC-F ≥4 | p value |
|------------------|----------|-----------|-----------|---------|
|                  | 179      | 120       | 59        |         |
| Handgrip strength men <28 kg, female <18 kg | 85 (47.5) | 45 (37.5) | 40 (67.8) | <0.001  |
| Usual gait speed <1.0 m/s | 47 (26.3) | 14 (11.7) | 33 (55.9) | <0.001  |
| Sit to stand ≥12 s | 52 (29.1) | 19 (15.8) | 33 (55.9) | <0.001  |
| SPPB ≤9          | 41 (22.9) | 11 (9.2)  | 30 (50.9) | <0.001  |
| Low physical performance | 60 (33.5) | 22 (18.3) | 38 (64.4) | <0.001  |
| SMI men <7.0 kg/m², female <5.7 kg/m² | 58 (32.4) | 37 (30.8) | 21 (35.6) | 0.522   |

Values are expressed as n (%) of patients. SMI, skeletal muscle mass; SPPB, short physical performance battery.

**Discussion**

This cross-sectional study showed that 59 (33.0%) patients on hemodialysis had an SARC-F score of ≥4, and 49 (27.4%) patients had sarcopenia according to the AWGS2019 criteria. Higher SARC-F scores were significantly associated with a higher likelihood of sarcopenia diagnosed using the AWGS2019 criteria and lower muscle strength and physical performance. We found that the SARC-F had moderate sensitivity and specificity with respect to the screening ability. In addition, in the SARC-F <4 group, 28 (23.4%) patients with sarcopenia or severe sarcopenia diagnosed using the AWGS2019 criteria had been overlooked. Our results suggest that the SARC-F might be a useful tool to screen for low muscle strength and physical performance; however, it has limited screening ability for correctly identifying patients with sarcopenia among those undergoing hemodialysis. To the best of our knowledge, this is the first study to explore the validity of the SARC-F as a screening tool for sarcopenia, defined by the AWGS2019 criteria, in patients on hemodialysis.

In this study, the prevalence of sarcopenia or severe sarcopenia was 27.4%, and the sensitivity and specificity of the SARC-F for sarcopenia were 42.9% and 70.8%, respectively. Similar accuracy was reported in a previous study conducted among hospitalized patients, which showed that the prevalence of sarcopenia defined by the AWGS2019 criteria was 50.1–61.1%, and the sensitivity and specificity were 49.1–62.3% and 71.4–81.2%, respectively [30, 31]. In contrast, a study among community-dwelling older adults [32] reported that the prevalence of sarcopenia and severe sarcopenia was 22.8% and 6.8% and showed lower sensitivity (10.4–23.9%) and higher specificity (92.8–93.6%) values of the SARC-F than those obtained in our study. The probable reasons for the varying accuracy of the SARC-F across studies could be the...
differences in the prevalence of sarcopenia in these populations. Generally, the sensitivity of a test is higher in a population with a higher prevalence of the target disease. In addition, the specificity tends to be lower in subjects with comorbidities (i.e., patients on hemodialysis and under hospital settings) due to a higher rate of false positives, depending on the severity of the comorbidities and disease-related pathology.

In the present study, the AUCs of SARC-F for the AWGS2019 were low, and the SARC-F <4 group included 28 (23.4%) patients with sarcopenia or severe sarcopenia. The probable reason for this finding was that 24 patients in the SARC-F <4 group had cognitive decline (MMSE <24). Previous studies have reported that patients with lower cognitive function are more likely to overestimate their mobility [33, 34]. Therefore, cognitive decline might have led to the misclassification of these patients.

In the AWGS2019 guidelines, the SARC-F is suggested as an initial tool before completing a more thorough assessment for sarcopenia using more complicated physical performance tests and body composition assessments, which is the procedure for serial testing [35]. Given the present findings indicating that the SARC-F has a low to moderate sensitivity and specificity for the diagnosis of sarcopenia, it might be more practical to use it in combination with objective assessment measures (i.e., physical performance tests), rather than as a first-step screening tool, to ensure that sarcopenia is not overlooked in patients on hemodialysis.

This study has several limitations. First, the study targeted Japanese patients receiving hemodialysis at a single center. Furthermore, the BIA parameters may vary depending on lifestyle habits, such as diet; therefore, our results might have limited generalizability, and further validation studies across other Asian countries are necessary. Second, we assessed the muscle mass using BIA prior to a dialysis session, which could lead to an overestimation of the muscle mass in the setting of overhydration [36]; thus, the true prevalence of sarcopenia might have been underestimated. Future studies are necessary to validate sarcopenia defined by muscle mass measured after dialysis or by using different measuring equipment (i.e., dual-energy X-ray absorptiometry and magnetic resonance imaging). Third, in this study, gait speed was measured using the 10-m walking test. The AWGS2019 recommends the measurement of the 6-m gait speed, and it cannot be ruled out that the results may differ from those measured using the 10-m walk test. Fourth, cognitive impairment was assessed using the MMSE; however, the MMSE alone may not be sufficient for diagnosing cognitive impairment. Therefore, cognitive dysfunction may have been overestimated or underestimated. Finally, this study did not distinguish between patients with arteriovenous fistulas or catheters as vascular access for hemodialysis. The quality of dialysis and inflammatory status may have been affected, which in turn may have modified the degree of malnutrition and sarcopenia. Therefore, it cannot be ruled out that the investigation of the dialysis quality may have been insufficient.

| Definitions | Sensitivity, % (95% CI) | Specificity, % (95% CI) | PPV, % (95% CI) | NPV, % (95% CI) | AUC (95% CI) |
|-------------|------------------------|------------------------|----------------|----------------|--------------|
| Sarcopenia  | 42.9 (28.8–57.8)       | 70.8 (62.2–78.4)       | 35.6 (23.6–49.1) | 76.7 (68.1–83.9) | 0.57 (0.49–0.65) |
| Severe sarcopenia | 66.7 (44.7–84.4) | 72.3 (64.5–79.1) | 27.1 (16.4–40.3) | 93.3 (87.3–97.1) | 0.70 (0.59–0.80) |

AUC, area under the curve; AWGS2019, Asian Working Group for Sarcopenia; CI, confidence interval; NPV, negative predictive value; PPV, positive predictive value; SARC-F, Strength, Assistance in walking, Rise from a chair, Climb stairs, and Falls.

Conclusions

We investigated the diagnostic ability of the SARC-F to diagnose sarcopenia and severe sarcopenia, as defined by the AWGS2019, among patients on hemodialysis. SARC-F ≥4 had low to moderate sensitivity and specificity for sarcopenia. In clinical practice, careful interpretation might be necessary to diagnose sarcopenia using only the SARC-F in patients on dialysis. Further, as the working groups for sarcopenia suggest, a comprehensive screening with objective assessments, in addition to the SARC-F, might be necessary.

Acknowledgments

The authors thank all patients who participated in this study and the HD treatment staff at the Sagami Circulatory Organ Clinic for their contributions to this study.
Statement of Ethics

This study was performed according to the ethical principles of the Declaration of Helsinki and was approved by the research ethics committee. The patients provided written informed consent prior to study participation.

Conflict of Interest Statement

The authors declare no conflicts of interest.

Funding Sources

This study was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI, Grant No. JP19K11372, received by Dr. Matsunaga.
