HIGH-CODIMENSIONAL KNOTS SPUN ABOUT MANIFOLDS

DENNIS ROSEMAN AND MASAMICHI TAKASE

ABSTRACT. Using spinning we analyze in a geometric way Haefliger’s smoothly knotted \((4k-1)\)-spheres in the \(6k\)-sphere. Consider the 2-torus standardly embedded in the 3-sphere, which is further standardly embedded in the 6-sphere. At each point of the 2-torus we have the normal disk pair: a 4-dimensional disk and a 1-dimensional proper sub-disk. We consider an isotopy (deformation) of the normal 1-disk inside the normal 4-disk, by using a map from the 2-torus to the space of long knots in 4-space, first considered by Budney. We use this isotopy in a construction called spinning about a submanifold introduced by the first-named author. Our main observation is that the resultant spun knot provides a generator of the Haefliger knot group of knotted 3-spheres in the 6-sphere. Our argument uses an explicit construction of a Seifert surface for the spun knot and works also for higher-dimensional Haefliger knots.

1. INTRODUCTION

Various kinds of spinning constructions, all of which stem from Artin’s original construction [1], are now basic tools in the study of high-dimensional knots in codimension two, that is, in the study of embeddings of \(n\)-manifolds in the \((n+2)\)-sphere.

On another front, Haefliger found smooth knots in codimensions greater than two [11, 12]. He showed that the group \(C^n_q\) of isotopy classes of smooth embeddings of the \(n\)-sphere \(S^n\) into \((n+q)\)-sphere \(S^{n+q}\) is often non-trivial even when \(q \geq 3\). Although many spinning constructions can be applied for such “high-codimensional” knots, there have been very few related studies [4, 13, 15].

Budney [4] gave a new description of a generator of the Haefliger knot group \(C^3_3\). This was related to his study on the space \(K_{4,1}\) of “long” knots in 4-space. Here, \(K_{n,j}\) is the space of long knots — smooth embeddings of \(\mathbb{R}^j \hookrightarrow \mathbb{R}^n\) which are standard outside the unit disk in \(\mathbb{R}^j\). We note that the restriction of a long embedding to the unit disk gives a properly embedded \(j\)-disk in the unit \(n\)-disk — our construction will refer to it. In his paper, a map (the resolution map) \(\Phi: T^2 \to K_{4,1}\) from the 2-torus \(T^2\), defined in an ingenious way (see §2.2), plays a key role. This map gives rise to generators of certain homotopy groups and of the Haefliger group, via successive graphing constructions. The geometric nature of graphing constructions here is a high-codimensional version of Litherland’s deform-spinning.

We give yet another description of a generator of the Haefliger knot group \(C^3_3\) in terms of the notion spinning about a submanifold, introduced by the first-named author [16]. Our main result is as follows (see §3 for the details). Consider the 2-torus \(T^2\) standardly embedded in \(S^3\), which is further standardly embedded in \(S^6\). At each point of \(T^2\), we have the normal 4-disk \(D^4\) to \(T^2 \subseteq S^6\) and the normal

1-disk $D^1$ to $T^2 \subseteq S^3$. Then, we “deform” $D^1$ inside $D^4$, by using $\Phi$. Namely, at each point of $\tau \in T^2$, we replace the standard disk pair $(D^4, D^1)$ with the new disk pair $(D^4, \Phi(\tau)(D^1))$. We then show that the resultant smoothly embedded 3-sphere $\Sigma_\Phi \subseteq S^6$ represents a generator of the Haefliger knot group $C^3_3$.

Our study is motivated by Budney’s construction and in particular his resolution map $\Phi: T^2 \to \mathcal{K}_{4,1}$. Our approach is different. We use a basic technique in the spirit of codimension two knot theory — examination of how the homology of a Seifert surface relates the knot complement. It is very geometric, uses higher-dimensional visualization, does not involve any homotopy groups and might be useful for more general high-codimensional knots.

Additionally, all of Budney’s and our arguments work for higher-dimensional Haefliger knot groups $C^{2k+1}_{4k-1}, k \geq 2$. We need just to consider the triple

$$S^{2k-1} \times S^{2k-1} \subseteq S^{4k-1} \subseteq S^{6k}$$

and use everywhere a higher-dimensional Budney map $[4, \S 5]

$$S^{2k-1} \times S^{2k-1} \to \mathcal{K}_{2k+2,1}$$

instead of $\Phi: T^2 = S^1 \times S^1 \to \mathcal{K}_{4,1}$.

Throughout the paper, we work in the smooth category; all manifolds and mappings are supposed to be differentiable of class $C^\infty$, unless otherwise stated. We use the symbol ‘$\cong$’ for a group isomorphism and ‘$\sim$’ for a diffeomorphism. Some graphics are shown piecewise smooth — they correspond to unique smooth manifolds by rounding of corners.

The second-named author would like to thank Ryan Budney for fruitful conversations.

2. Preliminaries

2.1. Haefliger’s knots. Haefliger showed in [11, 12] that the group $C^q_n$ of smooth isotopy classes of smooth embeddings of the $n$-sphere $S^n$ in the $(n+q)$-sphere $S^{n+q}$ is often non-trivial even when the codimension $q$ is greater than 2. In a particular case, for each $k \geq 1$ the group $C^4_{4k-1}$ of smooth isotopy classes of smooth embeddings $S^{4k-1} \hookrightarrow S^{6k}$ forms the infinite cyclic group $\mathbb{Z}$. This is in contrast with Zeeman’s unknotting theorem [20] claiming that any $n$-sphere is unknotted in the piecewise linear sense in the $(n+q)$-sphere if $q > 2$.

According to [2, 3, 19, 18], the smooth isotopy class of Haefliger’s knot can be read off from geometric characteristics of its Seifert surface. When $k = 1$, we have the following ([10, 3]).

**Theorem 2.1.** Every embedding $F: S^3 \hookrightarrow S^6$ has a Seifert surface $\widetilde{F}: V^4 \hookrightarrow S^6$ and

$$\Omega(F) = -\frac{1}{8}(\sigma(V^4) - e_{\widetilde{F}} - e_{\widetilde{F}})$$

gives the isomorphism $\Omega: C^3_3 \to \mathbb{Z}$, where $e_{\widetilde{F}}$ denotes the normal Euler class of $\widetilde{F}$.

2.2. Budney’s isomorphism. Several papers including [2, 3, 10, 19, 18, 17] give geometric descriptions for the Haefliger knot groups $C^{2k+1}_{4k-1}$ and their generators. Recently, Budney [4] has given a description of such Haefliger knots in terms of the space of long knots, which is related to the Litherland-type deform-spinning.
Let $\mathcal{K}_{n,j}$ be the space of smooth embeddings (long embeddings) $\mathbb{R}^j \hookrightarrow \mathbb{R}^n$ being the standard inclusions on $|x| \geq 1$ for $x \in \mathbb{R}^j$. Then, Budney [4], using results in [9], showed that there is an isomorphism $\pi_2\mathcal{K}_{4,1} \cong C_3^1$. His isomorphism gives a new description of the Haefliger group $C_3^1 \approx \mathbb{Z}$.

We briefly review Budney’s construction. Note that he deals with more general cases in [4, §5].

2.2.1. The graphing map. Consider the “graphing” map $\text{gr}_1: \Omega \mathcal{K}_{n-1,j-1} \to \mathcal{K}_{n,j}$ defined by

\[(\text{gr}_1 f)(t_0, t_1, \ldots, t_{j-1}) = (t_0, f(t_0)(t_1, \ldots, t_{j-1})).\]

Budney [4] showed that the maps $\Omega^2\mathcal{K}_{4,1} \to \Omega \mathcal{K}_{5,2} \to \mathcal{K}_{6,3}$ between the loop spaces induce isomorphisms

\[\pi_2\mathcal{K}_{4,1} \cong \pi_1\mathcal{K}_{5,2} \cong \pi_0\mathcal{K}_{6,3}.\]

Furthermore, the group $\pi_0\mathcal{K}_{6,3}$ is isomorphic to $C_3^1$ due to [12].

2.2.2. The resolution map $\Phi: T^2 \to \mathcal{K}_{4,1}$. Take a “long” immersion $f: \mathbb{R} \to \mathbb{R}^3 \subseteq \mathbb{R}^4$ such that $f(t) = (t, 0, 0, 0)$ for $|t| > 1$ and has two double points $f(t_1) = f(t_3), f(t_2) = f(t_4)$ with $-1 < t_1 < t_2 < t_3 < t_4 < 1$ and such that $df(T_{t_1}\mathbb{R}) \cap df(T_{t_3}\mathbb{R}) = df(T_{t_2}\mathbb{R}) \cap df(T_{t_4}\mathbb{R}) = \{0\}$ (see Figure 1). At $f(t_1) = f(t_3)$ and $f(t_2) = f(t_4)$, we have the 2-dimensional normal complements $P_1$ to $df(T_{t_1}\mathbb{R}) \oplus df(T_{t_3}\mathbb{R})$ and $P_2$ to $df(T_{t_2}\mathbb{R}) \oplus df(T_{t_4}\mathbb{R})$, respectively.

![Figure 1](image)

**Figure 1.** An immersed long line with two intersections, thickened and shown as a thin tube.

Let $S_1$ and $S_2$ be the unit 1-dimensional sphere in $P_1$ and $P_2$ respectively. Given $(\theta, \psi) \in S_1 \times S_2$, we perturb a small neighborhood of $f(t_1)$ in direction $\theta$ using a bump function and a small neighborhood of $f(t_2)$ with $\psi$. In this way, we can eliminate the double points, separating via a fourth dimension. Thus we obtain a “resolution map”

\[\Phi: T^2 = S_1 \times S_2 \to \mathcal{K}_{4,1}.\]

Finally, Budney showed that $\Phi$ generates $H_2(\mathcal{K}_{4,1}; \mathbb{Z})$ and hence generates $\pi_2\mathcal{K}_{4,1} \cong \mathbb{Z}$ since $\mathcal{K}_{4,1}$ is simply-connected [5].
2.3. **Deform-spinning about a submanifold.** The spinning describes several methods of constructing higher-dimensional knots from lower-dimensional knots. The most fundamental method, simply called spinning, is due to Artin [1]. It has been generalized in various ways (a useful reference in this area is [8]). In this paper, we will use the deform-spinning about a submanifold (in [8] called frame deform-spinning), introduced in [16].

**Definition 2.2.** Suppose $M^k$ is a submanifold of $S^p \subseteq S^q$ with trivial tubular neighborhood $N \approx M^k \times D^{q-k} \subseteq S^p$. Then $M$ has a trivial tubular neighborhood $T \approx M^k \times D^{q-k}$ in $S^q$. We can write:

$$(T, N) = M^k \times (D^{q-k}, D^{p-k}).$$

Suppose $\Phi: M^k \to \mathcal{K}_{q-k,p-k}$ is a smooth map. The deform spun knot $\Sigma_\Phi$ about $M^k$ is the embedded $p$-sphere in $S^q$, obtained from $S^p \subseteq S^q$ by replacing the standard ball pair $\{x\} \times (D^{q-k}, D^{p-k})$ with $\{x\} \times (D^{q-k}, \Phi(x)(D^{p-k}))$ at each point $x \in M^k$.

This generalizes Litherland’s deform-spinning [14], that corresponds to the case where $M^k$ is taken as $S^i$ standardly embedded in $S^p \subseteq S^{p+2}$.

Deform-spinning about a submanifold is one of the most generalized form of spinning. For example, we can describe Artin’s original spinning as $\Sigma_\Phi$, where $M^k = S^3$ in $S^2 \subseteq S^3$ and $\Phi$ is a constant map. A super-spun $p$-knot [6] is given by deform-spinning about $M^k = S^k \subseteq S^p$ with a constant map $\Phi$. Zeeman’s twist-spun knot [21] is a deform-spun knot about $M^k = S^1 \subseteq S^2 \subseteq S^3$ via the map $\Phi: S^1 \to \mathcal{K}_{3,1}$; where $\Phi(\theta)$ is the rotated image of a knotted arc about the $x$-axis by an angle of $\theta$. Another variation is Fox’s roll-spinning [7]. Yet another extension spinning of a knot about a projection of a knot uses a mapping of a manifold into $S^p$ [16].

3. **The main theorem**

Consider the 2-torus $T^2$ standardly embedded in $S^3$, which is further included in $S^6$ in the standard manner: $T^2 \subseteq S^3 \subseteq S^6$. At each point of $T^2$ we consider the normal 4-disk to $T^2 \subseteq S^6$ and the normal 1-disk to $T^2 \subseteq S^3$, which form the standard disk pair $(D^4, D^1)$.

We can deform-spin $S^3 \subseteq S^6$ about the torus $T^2 \subseteq S^3 \subseteq S^6$ with Budney’s resolution map (2.2.2) $\Phi: T^2 \to \mathcal{K}_{4,1}$. In the normal plane at each point $\tau \in T^2$, we replace the standard disk pair $(D^4, D^1)$ with a new disk pair $(D^4, \Phi(\tau)(D^1))$. We denote the resultant embedded 3-sphere in $S^6$ by $\Sigma_\Phi$. Namely, in $S^6$

$$\Sigma_\Phi = S^3 \setminus (T^2 \times D^1) \cup \bigcup_{\tau \in T^2} \Phi(\tau)(D^1).$$

Let $J: S^3 \hookrightarrow S^6$ be a smooth embedding so that $J(S^3) = \Sigma_\Phi \subseteq S^6$. Then, our main theorem is the following:

**Theorem 3.1.** $\Omega(J) = \pm 1$; $J$ represents a generator of $C_3 \cong \mathbb{Z}$.

4. **A Seifert surface and the proof**

Consider the 2-torus $T^2 \subseteq S^3 \subseteq S^6$, along which we performed the spinning, to be

$$T^2 = S^3_\theta \times S^3_\psi = \{ (\theta, \psi); \theta, \psi \in \mathbb{R}/2\pi\mathbb{Z} \}.$$
At each point \((\theta, \psi) \in \mathbb{T}^2\), we identify the normal 4-disk \(D^4_{(\theta, \psi)}\) to \(\mathbb{T}^2 \subseteq S^6\) with the unit disk \(D^4\) in \(\mathbb{R}^4 = \{(x, y, z, w)\}\). Thus, \(((\theta, \psi), (x, y, z, w))\) gives a coordinate system for a tubular neighborhood (diffeomorphic to \(\mathbb{T}^2 \times D^4\)) of \(\mathbb{T}^2\) in \(S^6\).

Let \(\mathbb{B}^4\) be the northern hemisphere of \(S^4 \subseteq S^6\), which we think of the standard Seifert surface for the unknot \(S^3 \subseteq S^6\). We can assume that in each normal 4-disk \(D^4_{(\theta, \psi)}\) to \(\mathbb{T}^2 \subseteq S^6\), the 4-disk \(\mathbb{B}^4\) is seen as in Figure 2, which depicts the hyperplane section by \(w = 0\) of \(D^4_{(\theta, \psi)}\) and where the intersection of \(\mathbb{B}^4\) and \(D^4_{(\theta, \psi)}\) is shown in gray. We denote this intersection \(\mathbb{B}^4 \cap D^4_{(\theta, \psi)}\) by \(\mathbb{B}^2_{\theta, \psi}\).

4.1. A Seifert surface. To construct a Seifert surface for our spun knot \(\Sigma^3_\Phi \subseteq S^6\), we first consider the punctured 2-dimensional torus in the 4-disk \(D^4_{(0,0)}\), as shown in Figure 3. In Figure 3, \(\Sigma^3_\Phi\) is the arc drawn with a thick line. We remark that although this arc appears knotted since it is pictured in three-dimensional space, it is really unknotted in \(D^4_{(0,0)}\). We view \(\tilde{T}_{(0,0)}\) in a standard way as a 2-disk \(C\) with two bands \(A\) and \(B\), as in Figure 4.

In the normal 4-disk \(D^4_{(\theta, \psi)}\) for general \((\theta, \psi) \in \mathbb{T}^2\), we consider the embedded punctured 2-torus \(\tilde{T}_{(\theta, \psi)}\), defined as follows. The punctured torus \(\tilde{T}_{(\theta, \psi)}\) coincides with \(\tilde{T}_{(0,0)}\) on the disk \(C\) and differs from \(\tilde{T}_{(0,0)}\) only on the two bands \(A\) and \(B\). In the punctured torus \(\tilde{T}_{(\theta, \psi)}\), the band \(A\) has been replaced with \(A_{\theta}\) and \(B\) has been replaced with \(B_{\psi}\): \(\tilde{T}_{(\theta, \psi)} = C \cup A_{\theta} \cup B_{\psi}\). Now we describe the band \(A_{\theta}\) in detail; \(B_{\psi}\) will be treated similarly.
We obtain \( A_{\theta} \) by rotating \( A \) around the 2-dimensional axis \( \{w = z = 0\} \) by an angle of \( \gamma(y)\theta \), where \( \gamma(y) \) is a smooth bump function with \( \gamma(y) = 0 \) in a neighborhood of \( \pm 1 \) and \( \gamma(y) = 1 \) for \( -1/4 \leq y \leq 1/4 \) (see Figure 5). So \( \gamma \) allows us to smoothly attach the band \( A_{\theta} \) to \( C \). If we only consider the motion of the edges of
the band $A$ in the above process, it corresponds to Budney’s resolution process (see §2.2.2) for one intersection point.

To clarify this construction, we show $\overset{\circ}{T}(\pi,0)$ in Figure 6. In the generic case, the rotation will move points not in the center of the band so that it has non-zero $w$-coordinate and the points of $\overset{\circ}{T}(\theta,\psi)$ in $\{w=0\}$ is shown in Figure 7.

Putting together all the punctured tori $\overset{\circ}{T}(\theta,\psi) \subseteq D^4(\theta,\psi)$, we obtain the embedded 4-manifold

$$W' := \bigcup_{(\theta,\psi) \in \mathbb{T}^2} \overset{\circ}{T}(\theta,\psi) \approx \mathbb{T}^2 \times (\text{the punctured torus}) \subseteq S^6.$$
then, \[
W := \mathbb{R}^4 \setminus \bigcup_{(\theta, \psi) \in \mathbb{T}^2} \mathbb{B}^2(\theta, \psi) \cup \bigcup_{(\theta, \psi) \in \mathbb{T}^2} \hat{T}(\theta, \psi)
\]
becomes a smoothly embedded 4-manifold (a Seifert surface) bounded by the knot \(\Sigma^3 \subseteq S^6\). We abuse notation and identify \(W \subseteq S^6\) with the image of an embedding \(\tilde{f}: W \hookrightarrow S^6\).

### 4.2. The second homology group.

Now let us compute the second homology group \(H_2(W; \mathbb{Z})\) of our Seifert surface \(W\) and its intersection form.

Since \(W'\) is diffeomorphic to \(\mathbb{T}^2 \times (\text{the punctured 2-torus})\), we have \(H_2(W') \approx \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}\), by the K"{u}neth lemma. If we take two closed curves \(\alpha, \beta\) in the punctured torus \(T_{(0,0)}^\circ\) at \((0, 0) \in S^1_\theta \times S^1_\psi\) as shown in Figure 8, then the above five \(\mathbb{Z}\)s are generated by the five tori \(T_{\alpha \theta} := \alpha \times S^1_\theta, T_{\alpha \psi} := \alpha \times S^1_\psi, T_{\beta \theta} := \beta \times S^1_\theta, T_{\beta \psi} := \beta \times S^1_\psi\) and \(\{\ast\} \times S^1_\theta \times S^1_\psi\), each embedded in \(W'\). Here \(\ast\) is a point of \(T_{(0,0)}^\circ\).

Since \(W\) is obtained by gluing \(D^4 \setminus \mathbb{T}^2 \times D^2\) (\(\approx\) the 4-disk) to \(W'\) along a part of their boundaries, killing \([\{\ast\} \times S^1_\theta \times S^1_\psi] \in H_2(W')\), we have \(H_2(W) \approx \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}\)

\[
\approx \langle [T_{\alpha \theta}] \rangle \oplus \langle [T_{\beta \theta}] \rangle \oplus \langle [T_{\alpha \psi}] \rangle \oplus \langle [T_{\beta \psi}] \rangle,
\]
by the Mayer-Vietoris sequence.
Among the above representatives of $H_2(W)$, the two pairs of “complementary” tori have intersection number 1. That is, the only non-zero intersection numbers are

$$[T_{\alpha\theta}] \cdot [T_{\beta\psi}] = [T_{\alpha\psi}] \cdot [T_{\beta\theta}] = 1,$$

where $\cdot$ denotes the intersection pairing. Hence, with respect to the above generators, the intersection form on $H_2(W)$ is expressed as

$$
\begin{pmatrix}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0
\end{pmatrix}.
$$

Note that the signature $\sigma(W) = 0$.

4.3. The normal Euler class. We compute the normal Euler class $e_j$ for the embedding $W \hookrightarrow S^6$ using an intersection argument.

Take a small generic perturbation $\hat{W}$ of $W$ in $S^6$ and put $F := \hat{W} \cap W$. Since $\Sigma_{\Phi}^3 = \partial W \subseteq S^6$ has trivial normal bundle, $F \subseteq \text{Int} W$ and the homology class $[F] \in H_2(W) \cong H_2(W, \partial W)$ is dual to the normal Euler class $e_j$.

With respect to the generators of $H_2(W)$ given in §4.2, we represent the class $[F]$ as

$$[F] = a_1[T_{\alpha\theta}] + a_2[T_{\beta\psi}] + a_3[T_{\alpha\psi}] + a_4[T_{\beta\theta}],$$

$$= (a_1, a_2, a_3, a_4) \in H_2(W) \cong \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}.$$

Then, with the intersection form in §4.2, we have, for example

$$a_2 = [F] \cdot [T_{\alpha\theta}].$$
If we let $\hat{T}_{\alpha\theta} \subseteq \hat{W}$ be the perturbation of $T_{\alpha\theta}$, then $a_2 = [F] \cdot [T_{\alpha\theta}]$ is equal to the intersection $F$ and $\hat{T}_{\alpha\theta}$ in $\hat{W}$. This is further equal to the intersection of $W$ and $\hat{T}_{\alpha\theta}$, since $F = \hat{W} \cap W$. Since $\hat{T}_{\alpha\theta}$ can be thought of as a push-off of $T_{\alpha\theta} \subseteq W$ into $S^6 \setminus W$, we only need to count the intersection of $W$ and a push-off of $T_{\alpha\theta}$. By the same method, we can compute $a_1, a_3, a_4$ and hence the class $[F]$ dual to the normal Euler class $e_F$. We carry out this calculation below.

First, the punctured 2-torus $\hat{T}_{(0,0)}$ at $(\theta, \psi) = (0, 0)$ lies in the 3-dimensional hyperplane $\{w = 0\}$, the hyperplane section by $w = 0$ of the normal 4-disk $D^4_{(0,0)}$. Consider a vector field $\nu$ normal to the punctured 2-torus $\hat{T}_{(0,0)}$ in this 3-dimensional hyperplane $\{(x,y,z,0)\}$. In each normal 4-disk $D^4_{(\theta,0)}$, we consider $(\theta,0) \times \alpha \subseteq \mathbb{T}^2 \times D^4$ to be sitting in $\hat{T}_{(\theta,0)}$ and push it off along the same normal vector field $\nu$. This determines a push-off $\hat{T}_{\alpha\theta}$ of the 2-torus $T_{\alpha\theta}$ in $S^6$.

In each normal 4-disk $D^4_{(\theta,0)}$, $W \cap D^4_{(\theta,0)} = \hat{T}_{(\theta,0)}$. As we vary $\theta$, this punctured torus, outside the A-band, lies in the 3-dimensional hyperplane $\{w = 0\}$ and the A-band lies in $\{(x,y,t \cos \theta, t \sin \theta) | t \in \mathbb{R}\}$. Therefore, the only way that $W$ and $\hat{T}_{\alpha\theta}$ could intersect is when $(\theta, \psi) = (\pi, 0)$.

Figure 9. Intersection of $\hat{T}_{\alpha\theta}$ and $W$. We see the A-band of $\hat{T}_{(\pi,0)} \subseteq W$. A part of $T_{\alpha\theta}$ is shown as a straight thin line segment parallel to the $y$-axis. The push-off $\hat{T}_{\alpha\theta}$ is a bold curve. For visualization, we show the trace of this push-off.

When $(\theta, \psi) = (\pi, 0)$, in the normal 4-plane $D^4_{(\pi,0)}$, the whole A-band lies in the 3-dimensional hyperplane $\{w = 0\}$. Figure 9 depicts the situation near the A-band in this 3-dimensional plane, where $\hat{T}_{\alpha\theta}$ is viewed as a “half-twisted arc” and the
$B$-band is an oppositely half-twisted band (Compare Figures 3 and 6). We see that the intersection of $W$ and $\hat{T}_{a\theta}$ consists of the two points $P$ and $Q$, seen in Figure 9.

However, it is not easy to see from Figure 9 the crucial fact that these intersections actually have the same sign. For this we use Figure 10.

Figure 10 shows a 3-dimensional sub-disk of $W$ intersecting a 2-dimensional sub-disk of $\hat{T}_{a\theta}$ transversely in 5-dimensional space. The array of black dots represent a square patch $S$ of $\hat{T}_{a\theta}$. The arrow in each figure represents a line segment of an $A$-band in $W$; thus the array of these segments represents a 3-cube of $W$.

Not shown is a sixth coordinate — the $\psi$ direction. This is a fourth coordinate for $W$ and the sixth coordinate of the ambient space — this coordinate will not be considered for analysis here. What really matters is the normal bundle to $W$ and tangent plane to the torus and these can be clearly understood using this figure. The $\theta$ corresponds to twisting of the first band $A$ and is independent from the twisting with respect to $\psi$.

In the fifth row of Figure 10 the arrow and the dot for each value of $y$ are both in the $xz$-plane in \{w = 0\}. The one-parameter family of these two-dimensional figures, when stacked, give rise to the three dimensional Figure 9.

We will be concerned with the two intersection points of our torus $\hat{T}_{a\theta}$ and the 4-manifold $W$. In Figure 10 these points occur where the black dot lies exactly on the arrow — $P$ in row 5 column 3; and $Q$ in row 5 column 7. Choose an orientation of the tangent bundle of $\hat{T}_{a\theta}$ and an orientation of the normal bundle of $W$. Transversality assures that, at each point of $W \cap \hat{T}_{a\theta}$, we can identify two-dimensional fibers of these bundles. The sign at the intersection point $P$ is $+1$ if the two orientations agree, and $-1$ if not.

The square patch $S$ of $\hat{T}_{a\theta}$ is flat in the $\theta xyz$-cube, thus its tangent plane coincides with this square $S$. Specifically, orient $\hat{T}_{a\theta}$ with vectors $\tau_y$ in the $y$ direction (that is along the rows from left to right in Figure 10) and $\tau_\theta$ the $\theta$ direction (down the columns of Figure 10). This ordered pair $(\tau_y, \tau_\theta)$ gives an orientation of the tangent plane of $\hat{T}_{a\theta}$. Next we chose a framing for the normal bundle for $W$. The normal 2-disks to $W$ are all represented as disks normal to the arrow. In row 5 column 1 we orient the normal disk $W$ by a vector pair $(\omega_1, \omega_2)$ where $\omega_1$ is in the direction of the $z$-axis and $\omega_2$ in direction of the $w$-axis. Continuing in the fifth row, we choose $\omega_1$ orthogonal to the arrow in the gray disk and $\omega_2$ in the direction of the $w$-axis. (The details of the normal frames in other rows will not need to be considered in our analysis.)

We first focus on $\tau_y$ at $P$ — row 5 column 3. As we go from left to right, the arrow rotates in the disk while the dot rotates in the opposite direction. The dot from the positive side of the arrow (with respect to $\omega_1$) to the negative side. It follows that, at $P$, $\tau_y = -\omega_1$. Similarly at $Q$ (row 5 column 3) the dot goes from the negative side back to the positive side. Thus at $Q$, $\tau_y = +\omega_1$. This can be seen also in Figure 9.

Next we consider $\tau_\theta$ at $P$. This second tangent direction is downwards the third column. Note that as the dot passes $P$ it goes from below the disk (that is, hidden from view) to above it (visible). This is in the direction of the positive $w$-axis. Thus at $P$, $\tau_\theta = \omega_2$. At $Q$ we see the dot go from above the disk to below it and so at $Q$, $\tau_\theta = -\omega_2$. This information is not apparent in Figure 9.
In summary the intersection numbers at $P$ and $Q$ are both $-1$. However, this sign depends on our choice of orientation of $\hat{T}_{\alpha\theta}$, so we can only conclude that the signs at $P$ and $Q$ are the same.

Thus, we conclude:

$$a_2 = [F] \cdot [T_{\alpha\theta}] = \pm 2.$$ 

By the same argument for $\beta$, $\psi$ and the $B$-band instead of $\alpha$, $\theta$ and the $A$-band, we have $a_1 = \pm 2$.

For the two tori $[T_{\alpha\psi}]$ and $[T_{\beta\theta}]$, we can easily check that their push-offs along the same normal field $\nu$ do not intersect $W$ at all. Therefore, we have $a_3 = a_4 = 0$.

Finally, the homology class dual to the desired normal Euler class is

$$[F] = (\pm 2, \pm 2, 0, 0) \in H_2(W) \cong \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}.$$
Thus, we have

**Proposition 4.1.** \( e_f = (\pm 2, \pm 2, 0, 0) \in H^2(W) \).

4.4. **Proof of Theorem 3.1.** To prove Theorem 3.1, we have only to compute the Haefliger invariant \( \Omega(J) \) for our spun knot \( \Sigma_3^3 \cup S \subseteq S^6 \) by using its Seifert surface \( W \subseteq S^6 \) constructed in §4.1.

By Theorem 2.1, together with Proposition 4.1, we have

\[
\Omega(J) = -\left( \sigma(W) - e_f \sim e_f \right)/8
\]

\[
= \pm (2 \times 2 + 2 \times 2)/8 = \pm 1.
\]

This completes the proof of Theorem 3.1. \( \square \)

5. **Remarks**

In view of the proof in §4.4, we easily see the following.

**Remark 5.1.** In the construction of \( \Sigma_3^3 \cup S \subseteq S^6 \), by using \( \Phi'((\theta, \psi) := \Phi(m\theta, n\psi) \) \( (m, n \in \mathbb{Z}) \) for spinning (i.e. if we change the speed of the resolutions), we obtain the spun knot representing \( mn \) times the generator represented by \( \Sigma_3^3 \) in \( C^3 \).

All of our arguments are valid for higher-dimensional Haefliger knots \( C^{2k+1}_{4k-1}, k \geq 2 \). First of all, Budney’s resolution map is actually defined also in higher dimensions [4, §5] and our construction of the spun knot works there. Furthermore, since we also have higher-dimensional versions of Theorem 2.1 (see [19, Theorem 2.3] and [18, Theorem 5.1]), the proof is directly extended in high dimensions. Namely, we have:

**Remark 5.2.** If we deform-spin \( S^{2k-1} \subseteq S^{6k} \) about

\[ S^{2k-1} \times S^{2k-1} \subseteq S^{4k-1} \subseteq S^{6k} \]

via the higher-dimensional Budney map [4, §5]

\[ S^{2k-1} \times S^{2k-1} \to K_{2k+2,1} \]

(which corresponds to the case where we put \( n = 2k + 2 \) in Budney’s description of the generator of \( \pi_{2n-6}K_{n,1} [4, §5] \)), then the resultant spun knot represents a generator of \( C^{2k+1}_{4k-1} \) for \( k \geq 1 \). All the steps of the proof parallel those of the case \( k = 1 \) (§4) with little alteration.
