Abstract

Background: Immunophenotypic markers can play significant role in prognostic assessment for different cancers and leukocyte-associated Ig-like receptor (LAIR-1) is a recently identified inhibitory immuno-receptor. Methods: We measured LAIR-1 expression in paediatric ALL patients (n=42) and appropriate controls by flow cytometry. Median fluorescence intensities (MFIs) were calculated and correlated with demographic and clinical variables and early treatment outcome parameters. Results: The ALL cohort had an age range of 1 - 11 y and a M:F ratio of 2.5:1. 64% had WBC counts <50 x 10^9/L and 15 (36%) >50 x 10^9/L, 52% being standard risk and 48% high risk. There were 6 cases of T-ALL and 36 of B-ALL. AML1-TEL, E2A-PBX, BCR-ABL and MLL-AF4 transcripts were noted in 3, 6, 2 and 1 patient, respectively. Day 8 ABC was <1,000 in 31 and >1,000 in 8 cases, while 30 had low and 7 high MRD (both >0.01) at day 35 of treatment. The median MFI for LAIR-1 expression in control cases was 8.2 (range 7.76-11.69) and in ALL cases 4.02 (range 0.56 to 11.87), with 74% (n=31) of ALL cases showing reduced LAIR-1 expression. However, no significant correlations were found between standard ALL risk factors and LAIR-1 expression. Out of 42 patients, 4 died during induction treatment and one exited therapy, 60% (n=3/5) of these featuring low expression of LAIR-1. Also ALL patients with low LAIR-1 expression had t (12;21), t (1;19) and t (4;11) translocations in 2, 4 and 1 samples, respectively, but none had t (9;22). Of those with high LAIR-1 expression, 2 had t (9;22) (MFIs-14.43 and 11.87). Conclusions: This pilot study of LAIR-1 expression in ALL suggests low expression of the inhibitory molecule in leukemic cells. However, the findings need to be confirmed with larger cohort, along with studies focusing on pathophysiological roles in leukemic clone survival and escape from the immune system.

Keywords: Acute lymphoblastic leukemia- minimal residual disease- LAIR-1

Asian Pac J Cancer Prev, 19 (11), 3131-3135

Introduction

B-cell acute lymphoblastic leukaemia (B-ALL) is the most common type of childhood leukaemia accounting for 80-85% of cases. With improving supportive and diagnostic care and optimized treatment protocols the overall survival of B-ALL cases has improved over the years and varies from 85% to 90% in developed countries (Pui et al., 2015) to 67-74% in developing countries (Panja et al., 2015; Trehan et al., 2017). However there is constant ongoing research to look into newer prognostic markers in B-ALL that can be of utility for targeted therapies or predictors of disease relapse. Of these, Leukocyte-associated immunoglobulin-like receptor-1 (LAIR-1) has recently gained interest in acute leukemias as a possible immune evasion marker expressed on leukemic blasts (Florian et al., 2006; Meyard et al., 1997; Poggi et al., 1995; Poggi et al., 1998; Verbrugge et al., 2006). LAIR-1 (CD305) is an ITIM associated inhibitory receptor and is expressed on most of the immune cells. It is a type I transmembrane glycoprotein containing one extracellular Ig-like domain and two ITIMs (Meyard et al., 1997). LAIR-1 is known to be expressed on various lineage of leukemic cells and a number of human AML cell lines, such as MV4-1, THP-1 and U937 as well as on B-ALL cell lines 697, Kasumi 2 and RCH-ACV (Kang et al., 2015). Collagen is the major ligand of LAIR-1 and in vitro experiments have confirmed its role in inhibiting immune cell activation (Lebbink et al., 2006; Lebbink et al., 2007). Previous studies have demonstrated that LAIR-1 mediates its immune inhibitory
function by cross linking itself on immune effector cells and initiating inhibitory signalling and thereby impeding the cell killing by NK cells or T cells and blocking the Ig and cytokine production by B cells (Meyaard et al., 1997; Poggi et al., 1995; Meyard et al., 1999; Ouyang et al., 2003; Massho et al., 2005; Poggi et al., 1997; Merlo et al., 2005).

Few studies till date have been reported on the expression and role of LAIR-1 in leukemia patients. In a study from a cohort of AML patients, it was demonstrated that haematopoiesis is unaffected on blocking the expression of LAIR-1 in normal cells but its inhibition suppresses the leukaemia progression since LAIR-1 helps in sustaining the survival and self-renewal properties of AML stem cells (Kang et al., 2015). Further in in-vitro and in-vivo (mouse model) experimentation by Chen et al., (2015), it was revealed that deletion of LAIR-1 can lead to cell death or remission of B-ALL respectively. However reports from cohorts of CLL patients suggests differently, showing that LAIR-1 is predominantly expressed in early stages of CLL and its expression is lower in patients with high-risk CLL (Perbellini et al., 2014). Thus the expression and role of LAIR-1 in different forms of leukaemia is still controversial. Considering above conflicting data on LAIR-1 expression and role in leukaemia progression, we prospectively analyzed the same in a cohort of paediatric ALL and correlated it with clinical variables and early treatment outcome parameters.

Materials and Methods

A total of 42 newly diagnosed pediatric cases (0-12 years) of acute lymphoblastic leukemia and ten children with normal hematological parameters as control were enrolled in the study. 1-2 ml of peripheral blood (blast count ≥80% in all patient samples) taken in EDTA coated vials was processed for flow cytometric analysis within 2-3 h by standard surface staining procedure. Briefly, APC conjugated CD45 (BD Biosciences) and FITC conjugated LAIR-1 (BD Biosciences) monoclonal antibodies were used to stain the cells followed by red blood cell lysis (ammonium chloride solution). The samples were washed twice with PBS and then acquired using Beckman Coulter flow cytometer. Unstained cells were used as negative control for staining and compensation was done using appropriate isotope matched negative control for anti LAIR-1. Cells with dim-intermediate CD45 positivity on SSC vs CD45 plot were gated and percentage positivity and mean fluorescence intensity (MFI) of LAIR-1 on these cells was analyzed.

The leukemia cases are routinely classified as B-/T-ALL by standard multicolor flow cytometry at our institute using an extended panel for acute leukemia including myeloid markers and MPO. The patients were stratified according to NCI risk criteria and treated as per modified ICICLE protocol which is an Indian adaptation of UKMRC 2003 protocol. Demographic and clinical variables of patients were noted and correlated with expression level of LAIR-1. The data was analyzed using SPSS 2.0 software. The association between two categorical variables was done using the chi-square test and p value <0.05 was considered statistically significant. Moods median method was performed to analyze any difference in LAIR-1 expression in control and case group.

The study was approved by Institutional Ethics Committee and Departmental review board. Informed consent of the inpatient/guardian was taken from all the cases enrolled in the study.

Results

LAIR-1 expression in control group (n=10)

LAIR-1 expression was first analyzed on lymphocytes of 10 pediatric control cases. The median of the MFIs of LAIR-1 expression on brightly positive CD45 lymphocytes was 8.2 (Figure 1) with lower and higher limits being 7.76 and 11.69 respectively (logarithmic scale). The expression of LAIR-1 on control samples was used to categorize the ALL cases into two groups (low or normal expression) based on the median MFI value.

LAIR-1 expression in ALL patients (n=42)

After setting the range of LAIR-1 expression in pediatric control samples, we analyzed LAIR-1 expression in a cohort of 42 children with ALL at the time of initial diagnosis. Seventy four percent (n=31) of patients showed lower expression of LAIR-1 while 26% (n=11) of cases had normal expression of LAIR-1 on lymphoblasts as compared to the control group (Figure 2). The ALL cases had MFI for LAIR-1 expression in the range of

LAIR-1 Expression in Pediatric Acute Lymphoblastic Leukemia

of AML1-TEL, E2A-PBX, BCR-ABL and MLL-AF4 were identified in 3, 6, 2 and 1 patient respectively. Day 8 absolute blast count (ABC) was noted to be <1,000 in 31 patients and 8 patients had >1,000 day 8 ABC count. Thirty patients had low MRD (<0.01) and 7 patients had high MRD (>0.01) status at day 35 of the treatment regime.

Correlation of LAIR-1 expression in patients with diagnosis and treatment parameters

On correlation of the two groups with low and normal LAIR-1 expression in ALL cases, no statistically significant association was noted with ALL risk factors, early treatment parameters or MRD status (Table 1). Out of 42 patients from our study cohort, four patients died during induction treatment and one left therapy. Sixty percent of the patients (n=3/5) with above event had low expression of LAIR-1. We also looked at the common fusion transcript expression profile of the patients and found that ALL patients with low LAIR-1 expression had t (12;21), t (1;19) and t (4;11) translocations in 2, 4 and 1 samples respectively but none of the patients had t (9;22). While in the case of patients with high LAIR-1 expression, 2 patients had t (9;22) and their MFIs were noted to be 14.43 and 11.87. Out of 11 patients having normal LAIR-1 expression 1 and 2 patients also had t (12;21) and t (1;19) respectively.

Discussion

LAIR-1 has recently been a subject of investigation as an immuno-phenotypic marker in different leukaemia’s. We at a tertiary care hospital and research centre in India examined the potential of this newly identified marker in our paediatric cohort of ALL patients. At this initial stage we looked at the expression level of LAIR-1 on immature lymphoid cells of newly diagnosed patients and tried to find any correlation with standard risk factors and early treatment outcome parameters. We noted that...
a significant number of ALL patients had lower level of LAIR-1 expression than control cases. Perbellini et al., (2014) have previously shown that lower expression of LAIR-1 is associated with high risk CLL patients that are expected to have worse clinical stage at diagnosis and poor biology. Similar observation was noted by Poggi et al., (2008) in a population of CLL patients. In our cohort as per NCI risk 20 cases were at high risk, however we could not correlate our data statistically due to the limited sample size.

In a report by Mirkowska et al., (2013) the MFI of LAIR-1 (CD305) expression on CD19+ B-cell population of leukemic and normal cells showed similar expression at the time of diagnosis and increased significantly in the MRD samples at day 15 of the treatment from the same sample. However, we in our study performed LAIR-1 expression analysis at a single time point only. In another study by Chen et al., (2015), LAIR-1 was found to be highly expressed in Philadelphia positive ALL and was associated with shorter overall and relapse-free survival. In our study we noted that two of the cases with BCR-ABL t (9;22) positivity that had higher expression of LAIR-1 with their MFI s (11.87 and 14.43) much higher than median of MFI s (4.2) of all the patients tested. No patient was reported to have BCR-ABL t (9;22) translocation in the group of low LAIR-1 expression. Although tested in the small cohort our data is in agreement with Chen et al., (2015)’s report.

Though significantly lower expression of LAIR-1 has been noted in pediatric ALL cases, the prognostic implication of same are limited since no correlation was observed between LAIR-1 expression and ALL risk and early treatment outcome parameters. It is hypothesized that normal to high LAIR-1 expression on lymphoblasts protects them from immune system, however this is mainly derived from in-vitro studies on AML cell lines and it needs to be seen how ALL clones behave. It is likely from our pilot study results that high risk sub-groups of ALL, like BCR-ABL positive clones may actually have high LAIR-1 expression and this may be a contributing factor in their evasion from immune cells to finally manifest as early or late relapse. However, larger prospective studies are still needed especially in cases with good and poor risk genetic abnormalities to better assess the significance of LAIR-1 as a prognostic marker or a potential therapeutic target.

Grant

Intramural Institute Grant (PGIMER, Chandigarh) for year 2015-2017; Grant No. 421.

Presentation

Poster presentation at ESMO Immunology Oncology Congress held in Geneva, Switzerland from 7-10th Dec 2017; Poster abstract No. 152 published as abstract in Supplement of Annals of Oncology No. 90P.

Disclosure of Interest

None.

Acknowledgments

The study was supported by Institutional research grant from PGIMER, Chandigarh. The authors declare no conflict of interest.
