visual hallucination, thought insertion/withdrawal, delusion of control and reference, and persecutory delusions.

Results: To date, 746 participants were recruited and of these, 3.2% of them has endorsed lifetime PLEs. Results showed that significantly higher depressive, anxiety and stress scores were found in those who has PLEs (p<0.001), and additionally, these scores significantly predicted the presence of PLEs in regression models (p<0.001).

Conclusions: Our preliminary findings highlighted the inter-related phenomena between PLEs and mood symptoms. Further investigation is needed to examine the likelihood of PLEs in predicting psychosis over time.

The enduring effects of adverse childhood experiences (ACES) on mood dysregulation in children: A literature review

F. Arain1,*, N. Chavannes1, C.C. Corona1, A. Tohid2, H. Arain3, M. Jennings1 and A. Sanchez-Lacay1
1Psychiatry, BronxCare Health System Mount Sinai, NY, United States of America; 2Psychiatry, University of Southern California, Los Angeles, United States of America and 3Under Graduate, Columbia University, New York, United States of America

Introduction: Behavioral dysregulation is a common presentation of children in the Emergency-Room (ER)1. A 10-year-old African-American boy with attention-deficit/hyperactivity disorder, oppositional defiant disorder with poor treatment adherence, two previous psychiatric hospitalizations and multiple ER visits, presented with dysregulation and aggressive behavior. He had inconsistent parenting and poor attachment with present involvement of child protective services. We did a systematic review to interpret associations between adverse childhood experiences (ACEs) and the development of behavioral dysregulation in later life.

Objectives: To see associations between ACEs and the development of behavioral dysregulation in later life.

Methods: We searched PsycINFO, APA PsycNet, PubMed, and Medline. Among 35 articles, five were included: 1) a meta-analysis of health consequences and ACEs2; 2) a data analysis of 64,329 youth from the Florida Department of Juvenile Justice that focused on suicide attempts and ACEs3; 3) a systematic review of 42 articles related to ACEs4; 4) data from 22,575 youth for childhood abuse, trauma and neglect 5 and 5) a multimodal logistic regression study on 64,000 juvenile offenders focused on ACE scores and latent trajectory.

Results: There is increased risk of substance use, mental and physical health problems, and violence associated with ACEs1,2,3. The relationship between childhood difficulties and suicide is interceded by adolescent’s maladaptive behaviors5. By age 35, ACEs increase the risk of becoming a serious juvenile offender4. Increased exposure to ACEs differentiates early-onset and sustained criminality from other forms of criminality6.

Conclusions: ACEs can affect the development of a child in multiple ways including suicidal behavior, aggression, impulsivity, criminality, academic difficulties and substance abuse

Smartphone internet addiction among hong kong young adults: The role of gender and depression

D.L. Chan1, C.S. Wong2,*, C.L. Hui1, S.K. Chan1 and E.H. Lee3
1Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong PRC; 2Department Of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong PRC and 3Department Of Psychiatry, The University of Hong Kong, HK, Hong Kong PRC

Introduction: Growing evidence studying pathological online behaviour has shown an increasing rate of internet addictions in younger populations across the globe.

Objectives: The current study aims to investigate the prevalence of smartphone internet addiction of youths in Hong Kong, and its associations with gender and depression.

Methods: A total of 1,164 participants’ preliminary data were extracted from the Hong Kong Youth Epidemiological Study of Mental Health, a territory-wide, household-based study of mental health in youths aged between 15-24. Internet usage behaviors, socio-demographic and psychosocial characteristics of the participants were assessed. The Chen Internet Addiction Scale was modified to measure smartphone internet addiction (SIA). Symptoms of depression were assessed using the Patient Health Questionnaire. Mann-Whitney U tests were used to examine (i) SIA across gender and (ii) depressive symptoms between high and no to low SIA groups. Linear regression model was used to evaluate the association between SIA and depression.

Results: The prevalence of smartphone internet addiction was 27.8% using the cut-off scores of 67/68. Women had higher SIA scores than men (U=144239.50, p=0.001). Participants with high SIA were associated with a higher severity in depression than those with no-to-low SIA (U=89187.00, p<0.001). Regression analysis revealed a significant positive correlation between depression and SIA after adjusting for confounding factors (B=0.099, t=9.138, p<0.001).

Conclusions: Our findings suggest a gender difference on online behaviour using smartphones. Further investigations are needed on whether SIA may exacerbate severity of common mental disorders.

Introduction: Psychosis are complex disorders due to their symptomatic and evolutionary heterogeneity. The genetic-environmental interaction model is the most accepted etiopathogenic model, in which neurobiological processes (genetic factors, connectivity and brain structure) and environmental factors (for example: childhood trauma) are studied. The association between
suffering traumatic events in childhood and the subsequent development of a Mental Disorder is of increasing interest.

**Objectives:** Analyze if a childhood trauma is a modulating factor of psychotic symptoms in patients with Mental Disorder. Analyze the implication of childhood trauma in long-term functionality.

**Methods:** The sample is made up of 37 patients with psychosis and their healthy brothers. Different sociodemographic, clinical and evolutionary variables were collected in all groups. The sample was evaluated using the semi-structured interview CASH, the WHODAS scale and the self-applied questionnaire CTQ.

**Results:** We did not find significant differences between the scores of CTQ between patients with psychosis and their healthy brothers. Sexual abuse is significantly correlated with the presence of hallucinations, inappropriate affect, formal thought disorders and catatonic symptoms. Emotional neglect is significantly correlated with the presence of hallucinations, inappropriate affect, affective blunting, and anhedonia. Physical neglect is significantly correlated with flatness and blunt affection. Sexual abuse is correlated with poorer personal care. Emotional neglect is correlated with poorer personal care, poorer family functioning, and worse overall functioning in the last year.

**Conclusions:** The intensity of traumatic experiences throughout childhood could be considered a modulating factor of psychotic symptoms (positive, negative, disorganized and catatonic) and overall functioning (occupational, family, social and personal care).

**Introduction:** The prevalence of adult Attention Deficit and Hyperactivity Disorder (ADHD) has been investigated in the general population by multiple studies. However, few studies have focused on identifying its prevalence in the military population, particularly among military parents of children with ADHD.

**Objectives:** The aim of our study was to screen for adult ADHD among military parents of ADHD children followed-up at the child and adolescent psychiatry department in the Military Hospital of Instruction of Tunis, Tunisia.

**Methods:** This prospective study was carried among military parents (one or both parents belonging to the national army) of ADHD children. Children were diagnosed with ADHD based on the 5th Diagnostic and Statistical Manual ADHD criteria and the Conners Comprehensive Behavior Rating Scale. Whereas adult ADHD was screened for using the Adult ADHD Self-Report Scale-V1.1.

**Results:** Fifteen children and twenty-nine parents were included in the study: sixteen of the parents were military members and thirteen were civilian spouses. Eight (50%) of the sixteen military parents, and four (30,7%) of the civilian spouses were screened positive for ADHD. Whereas 73% of these children had at least one parent screened positive for ADHD, and 53% had at least one military parent screened positive for ADHD. These results suggest a high prevalence of adult ADHD among this population.

**Conclusions:** ADHD occurs in childhood and may persist into adulthood. The findings of this study indicate that ADHD symptoms are not limited to the youth and are common in military population. Implications on screening, management, preventive measures and research should be discussed.
