The EF-hand calcium (Ca\textsuperscript{2+})-binding protein, neuronal Ca\textsuperscript{2+} sensor-1 (NCS-1/frequenin), is predominantly expressed in neuronal tissues and plays a crucial role in neuronal functions, including synaptic transmission and plasticity. NCS-1 has diverse functional roles, as elucidated in the past 15 years, which include the regulation of phosphatidylinositol 4-kinase III\(\beta\) (PI-4K-\(\beta\)) and several ion channels such as voltage-gated K\textsuperscript{+} and Ca\textsuperscript{2+} channels, the D2 dopamine receptors, and inositol 1,4,5-trisphosphate receptors (InsP\textsubscript{3}Rs). Functional analyses demonstrated that NCS-1 enhances exocytosis and neuronal survival after injury, as well as promotes learning and memory in mice. NCS-1 is also expressed in the heart including the Purkinje fibers (PFs) of the conduction system. NCS-1 interacts with K\textsubscript{v}4 K\textsuperscript{+} channels together with dipeptidyl peptidase-like protein-6 (DPP-6), and this macromolecule then composes the transient outward current in PFs and contributes to the repolarization of PF action potential, thus being responsible for idiopathic arrhythmia. Moreover, NCS-1 expression was reported to be significantly high at the immature stage and at hypertrophy in adults. That report demonstrated that NCS-1 positively regulates cardiac contraction in immature hearts by increasing intracellular Ca\textsuperscript{2+} signals through interaction with InsP\textsubscript{3}Rs. With the related signals, NCS-1 activates nuclear Ca\textsuperscript{2+} signals, which would be a mechanism underlying hormone-induced cardiac hypertrophy. Furthermore, NCS-1 contributes to stress tolerance in cardiomyocytes by activating mitochondrial detoxification pathways, with a key role in Ca\textsuperscript{2+}-dependent pathways. In this review, we will discuss recent findings supporting the functional significance of NCS-1 in the brain and heart and will address possible underlying molecular mechanisms.

Keywords: neuronal calcium sensor-1, frequenin, ion channel, survival, immature heart contraction, hypertrophy, nuclear Ca\textsuperscript{2+} signaling, learning and memory

NCS-1 AND ITS INTERACTING PROTEINS

Intracellular calcium (Ca\textsuperscript{2+}) is a versatile second messenger that regulates diverse cellular processes, including neurotransmission, muscle contraction, and signal transduction. Changes in intracellular Ca\textsuperscript{2+} are transduced by multiple proteins, with a key role of a large family of EF-hand Ca\textsuperscript{2+}-binding proteins that act as Ca\textsuperscript{2+} sensors or Ca\textsuperscript{2+} buffers. Ca\textsuperscript{2+}-buffer proteins chelate Ca\textsuperscript{2+} and
often terminate Ca\(^{2+}\) signals (Ikura, 1996). In contrast, the binding of Ca\(^{2+}\) to Ca\(^{2+}\)-sensor proteins causes a large conformational change, which consequently transduces the Ca\(^{2+}\) signal into various cellular functional changes, by regulating specific target proteins. Calmodulin is one of the best-characterized Ca\(^{2+}\)-sensor proteins and is involved in many aspects of Ca\(^{2+}\) signaling. Neuronal calcium sensor-1 (NCS-1) is the mammalian homolog of the Drosophila frequenin protein, which includes the larger NCS protein family that includes NCS-1, visinin-like proteins, recoverin, guanylate cyclase-activating proteins, and potassium channel-interacting proteins (KChIPs). The structure of NCS-1 is shown in the Figure 1A, indicating that it is a small (22 kDa) Ca\(^{2+}\)-binding protein containing 4 EF-hand motifs; of these, 3 (EF2-4) bind to Ca\(^{2+}\). Unlike ubiquitously expressed calmodulin, NCS-1 is predominantly expressed in the brain and cardiac tissues, suggesting its specialized roles in these tissues. The Ca\(^{2+}\)-binding affinity of NCS-1 is significantly higher than that of calmodulin (K\(d\) values of \(\sim 300\) nM vs. \(\sim 10\) \(\mu\)M, respectively). Although both Ca\(^{2+}\)-binding proteins can operate within the physiological range of Ca\(^{2+}\) levels (\(\sim 100\) nM to \(\sim 1–5\) \(\mu\)M), the above data suggest that NCS-1 may be more sensitive to small changes in intracellular Ca\(^{2+}\).

The functional roles of NCS-1 are still being elucidated. Currently, known functions include the regulation of diverse target proteins, including phosphatidylinositol 4-kinase (PI-4K), voltage- and ligand-gated ion channels, and interleukin-1 receptor accessory protein like-1 (IL1RAPL1). Here, we summarize the current understanding of NCS-1 regulation of some of these target proteins and how it affects brain and cardiac functions (Table 1). Even though NCS-1 has a well-characterized function in these organ systems, it should be pointed out that NCS-1 may have more diverse functions in human physiology and disease, such as a potential role in oncogenesis (Jerng et al., 2004). Such roles should be the focus of future studies.

### Phosphatidylinositol 4-Kinase

**Role in Exocytosis and Secretion**

PI-4K IIβ (PI-4K-β) catalyzes the synthesis of phosphatidylinositol 4-phosphate, which is a late limiting step in the synthesis of phosphatidylinositol 4,5-biphosphate, an important lipid regulator of many cellular functions including exocytosis. A yeast homolog of NCS-1 and PI-4-K interact, and NCS-1-induced activation of PI-4-K is required for yeast survival (Hendricks et al., 1999). Structural support for interaction was obtained from a recent NMR structure of Ca\(^{2+}\)-bound yeast NCS-1 (Ncs1) in complex with an N-terminal yeast PI-4-K (Pik1) fragment (Strahl et al., 2007). This interaction was also detected in neuroendocrine cells (Koizumi et al., 2003; Scalattar et al., 2002; Rajebhosale et al., 2003; de Barry et al., 2006), neurons (Taverna et al., 2002; Zheng et al., 2005) and other cell types including pancreatic beta cells (Gromada et al., 2005) and mast cells (Kapp-Barnea et al., 2003), and was shown to facilitate exocytosis and secretion in these cells (Table 1). However, previous reports have suggested no direct interaction in neurons (Bartlett et al., 2000).

This contradiction may be explained by the presence of newly discovered PI-4-Kβ regulators, calneurons. While calneurons interact with PI-4-K-β at low Ca\(^{2+}\) levels to inhibit its enzyme activity, NCS-1 binds to PI-4-K-β at high Ca\(^{2+}\) levels to activate it (Mikhaylova et al., 2009), suggesting that calneurons and NCS-1 compete for PI-4-K-β interaction depending on intracellular Ca\(^{2+}\) levels. Thus, when the intracellular Ca\(^{2+}\) level is low, its interaction might be difficult to be detected.

### Voltage-Gated Kv4 K\(^{+}\) Channels

**Regulation of Excitability in the Brain**

The V7 Drosophila mutant that overexpresses NCS-1 has a phenotype of hyperactivity, which results in the proposal that NCS-1 facilitates neurotransmission, possibly by regulating the activities of ion channels (Pongs et al., 1993; Poulain et al., 1994).

Indeed, we found that NCS-1 is a Ca\(^{2+}\)-sensitive regulatory component of a native K\(^{+}\) current (Nakamura et al., 2001; Table 1). In the brain and heart, rapidly inactivating (A-type) voltage-gated K\(^{+}\) currents control cellular excitability. Although the pore-forming alpha-subunits of these channels are considered to be Kv4 channels (Serôdio et al., 1994; Fiset et al., 1997; Nakamura et al., 1997), the kinetic properties of Kv4 channels differ from native A-type currents, suggesting the presence of regulatory subunits. KChIPs, a member of the NCS protein subfamily, were initially reported as a specific Kv4 regulatory subunit (An et al., 2000). Because NCS-1 modulates Kv4 currents similar to KChIPs, by increasing current amplitude and slowing the inactivation time course, and NCS-1 physically interacts with Kv4.2 in mouse brain, it was identified as a regulator of A-type K\(^{+}\) currents in neurons (Nakamura et al., 2001; Table 1).

**Involvement in Cardiac Arrhythmia**

This interaction and activation also occurs in adult mouse cardiomyocytes (Guo et al., 2002) and in zebrafish heart (Nakamura and Coetzee, 2008), which lacks KChIPs. The differential regulation of Kv4 channels by NCS-1 and KChIPs in specific tissues and cell types was an unaddressed topic, and this was clearly demonstrated in the report by Nattel’s group (Xiao et al., 2013). Purkinje fibers (PFs) show an unusual form of transient outward K\(^{+}\) current \(I_{to}\) with slow recovery kinetics and TEA sensitivity compared with ventricular \(I_{to}\), suggesting a distinct molecular composition. This group found that NCS-1 and DPP6, which were also reported to be auxiliary subunits of Kv4 K\(^{+}\) channels (Jerng et al., 2004), are preferentially enriched in PFs, while KChIP2, an essential subunit of ventricular Kv4.3 is weakly expressed. Moreover, NCS-1 slowed inactivation kinetics of Kv4.3, while DPP6 increased its current amplitude, thus increasing the \(I_{to}\) mediated K\(^{+}\) efflux (Figure 1Bb), which would accelerate PF repolarization and shortening of action potentials (Figure 1Bb; similar computer simulation was reported by Xiao et al., 2013). Thus, overexpression of Kv4 auxiliary subunits may result in steep transmural repolarization gradients in PFs with adjacent ventricular tissues that induces coupled ectopic activity, and potentially leads to lethal arrhythmias (Figure 1Bc).
also interacts with the anti-cancer drug taxol (Boehmerle et al., 2006), and is involved in the regulation of taxol-induced cardiac arrhythmia (Zhang et al., 2010). Thus, NCS-1 can be a potential target for anti-arrhythmic therapy.

Voltage-Gated Ca\textsuperscript{2+} Channels

Neurotransmitter Release and Neurite Elongation

NCS-1 regulates voltage-gated Ca\textsuperscript{2+} channels. Published data, however, are somewhat inconsistent with reports demonstrating...
both positive and negative effects (Table 1). NCS-1 was described to inhibit P/Q-type Ca\textsuperscript{2+} channels and regulates autocrine pathways in adrenal chromaffin cells (Weiss et al., 2000; Weiss and Burgoine, 2001) and N-type Ca\textsuperscript{2+} channels in PC12 cells, which reduces neurite elongation (Gambino et al., 2007). Other studies, in contrast, have demonstrated positive regulation of N-type Ca\textsuperscript{2+} channels, causing glial cell line-derived neurotrophic factor (GDNF)-induced enhancement of neurotransmitter release in motoneurons (Wang et al., 2001). Activation of P/Q-type Ca\textsuperscript{2+} channels by NCS-1 causes

activity-dependent synaptic facilitation in nerve terminals (Tsujimoto et al., 2002). In Drosophila, NCS-1 enhances neurotransmission and nerve terminal growth, by functionally interacting with the α1 subunit of the voltage-gated Ca$^{2+}$ channel (Dason et al., 2009). The possible reason for the apparent contradictory findings is that the effects may be cell type-specific and/or mediated by accessory proteins, such as a β-subunit (Rousset et al., 2003), or dependent on other interacting proteins, such as IL1RAPL1 that cooperatively regulates the N-type Ca$^{2+}$ channel via NCS-1 (Gambino et al., 2007). In addition, regulation of the Ca$^{2+}$ channel by Ca$^{2+}$ influx through the channel should be considered. Well-characterized examples are Ca$^{2+}$-dependent inactivation (Standen and Stanfield, 1982) and facilitation (Dolphin, 1996) of Ca$^{2+}$ channels regulated by other Ca$^{2+}$-binding proteins, such as calmodulin (Budde et al., 2002; Christel and Lee, 2012). Future research should aim to understand the regulatory mechanisms of Ca$^{2+}$ channels that involve NCS-1.

### D2 Dopamine Receptor

#### Role in Synaptic Plasticity and Psychiatric Illness

Dopamine plays an important role in the reward system of the brain. Disorders of the dopamine system result in several psychiatric and neurological conditions. Dopamine transmission is regulated by dopamine receptor-interacting proteins (DRIP), including NCS-1, calcyon, and DARPP-32. NCS-1 directly interacts with the D2 dopamine receptor, inhibits D2 receptor phosphorylation, and reduces the agonist-mediated internalization of the receptor (Kabbani et al., 2002), indicating that NCS-1 preserves dopamine signaling (Table 1). Indeed, modest NCS-1 overexpression in the dentate gyrus in mice promotes exploration, synaptic plasticity, and rapid acquisition of spatial memory (Saab et al., 2009). NCS-1 is upregulated in the prefrontal cortex of patients with schizophrenia and bipolar disorder (Koh et al., 2003; Bai et al., 2004). Because the levels of other DRIPs were also changed in patients with schizophrenia (Bai et al., 2004; Souza et al., 2008), DRIP signaling is possibly involved in psychiatric disorders. Furthermore, recent findings indicate the N-terminal 60 residues of NCS-1 are responsible for binding to the D2 receptor (Woll et al., 2011). Such knowledge would provide an opportunity to screen for drugs that can specifically interrupt the NCS-1-D2 dopamine receptor interaction and thus prevent psychiatric disorders.

#### Role in Learning and Memory and Possible Mechanism

Several studies have demonstrated that NCS-1 modulates learning and memory. For example, deletion or reduction of NCS-1 resulted in dysfunction of learning and memory in Caenorhabditis elegans (Gomez et al., 2001), as well as in mice (Mun et al., 2015), whereas mice overexpressing NCS-1 rapidly acquire spatial memory (Saab et al., 2009). Thus, NCS-1 affects neurophysiology, possibly through various interacting proteins. A mechanism underlying NCS-1-mediated learning and memory was further investigated (Nakamura et al., 2017). Ncs1$^{-/-}$ mice exhibited impaired spatial learning and memory function in the Morris Water Maze test, with slight changes in their exercise activity or a structural change in the hippocampus. However, the levels of brain-derived neurotrophic factor (BDNF), a key regulator of memory function, and dopamine were decreased. Furthermore, phosphorylation of Ca$^{2+}$/calmodulin-dependent protein kinase II-α (CaMKII-α), which regulates long-term potentiation, and BDNF levels were decreased, suggesting that CaMKII-α signaling that increases BDNF production is at least partly involved in NCS-1-mediated learning and memory function.

### Inositol 1,4,5-Trisphosphate Receptors

#### Role in Neuronal Pathogenesis

Ca$^{2+}$ signaling via inositol 1,4,5-trisphosphate receptors (InsP$_3$Rs) regulates cellular function and is involved in pathogenesis (Table 1). NCS-1 physically interacts with InsP$_3$R1 and enhances InsP$_3$R-mediated Ca$^{2+}$ signaling in rat brains. Indeed, physical/functional interaction of these proteins was directly demonstrated in an *in vitro* experiment showing that the addition of NCS-1 to InsP$_3$R1 in the lipid bilayer increased InsP$_3$R channel activity (Schlecker et al., 2006). This interaction was also detected at the growth cone region of neurites in cultured neurons, and indicated to be crucial for neurite outgrowth (Iketani et al., 2009). Metabotropic glutamate receptor-mediated cis also mediated by NCS-1/InsP$_3$R interaction (Jo et al., 2008). Pathologically, NCS-1/InsP$_3$R1 interaction is believed to be involved in bipolar disorder (Schlecker et al., 2006) because lithium, a medical drug for bipolar disorder, inhibited the NCS-1-induced enhancement of InsP$_3$R function. NCS-1/InsP$_3$R interaction is also considered to mediate neuropathy (Boehmer et al., 2006, 2007; Blachford et al., 2009), as paclitaxel (taxol), a chemotherapeutic agent used for the treatment of solid cancers, modulates the expression/function of NCS-1, and hence InsP$_3$R1-mediated Ca$^{2+}$ signaling.

#### Enhancement of Immature Heart Contraction and Hypertrophy

NCS-1/InsP$_3$R interaction is also detected in the heart and is crucial for contraction at the immature stage and cardiac hypertrophy in adult (Nakamura et al., 2011; Table 1 and Figure 1C). A high expression of NCS-1 was found in the immature heart (Nakamura et al., 2003, 2011), but its function at this stage was unknown. Using Ncs1$^{-/-}$ mice, Nakamura et al demonstrated that NCS-1 contributes to an increase in contraction and Ca$^{2+}$ signaling, specifically at the immature stage (Figure 1Cb). Intracellular Ca$^{2+}$ levels and the sarcoplasmic reticulum (SR) Ca$^{2+}$ content were significantly lower in Ncs1$^{-/-}$ myocytes at the neonatal stage than in wild-type cells. Mechanistically, the interaction of NCS-1 with InsP$_3$R increases InsP$_3$R-dependent Ca$^{2+}$ signaling, followed by the activation of CaMKII-dependent pathways, and promotes SR Ca$^{2+}$ pump via the phosphorylation of phospholamban (PLB), which ultimately induce increase in the SR Ca$^{2+}$ content and global Ca$^{2+}$ transient, thus cardiomyocyte contraction (Figures 1Ca,b). The importance of crosstalk among NCS-1, InsP$_3$Rs, and CaMKII in the immature hearts was evident.
by the high expression of all three proteins in immature hearts (Nakamura et al., 2011). In the neonatal mouse heart, the structure and function of SR are immature. Nonetheless, it is considered a primary source of Ca²⁺ necessary for muscle contractions, suggesting the existence of factors missing during development and promoting SR-dependent excitation-contraction (E-C) coupling in the postnatal stages. NCS-1 may act as one of these missing factors. Numbers of molecules which levels are high at the immature stage are often up-regulated in the disease conditions, such as cardiac hypertrophy. NCS-1 is also highly expressed during the early stages of hypertrophy in the disease conditions, such as cardiac hypertrophy. NCS-1 is act as one of these missing factors. Numbers of molecules which contraction (E-C) coupling in the postnatal stages. NCS-1 may contribute to NCS-1-mediated hypertrophy, which was described above. A possible mechanism underlying a dual effect process to rescue neuronal cell death. The signaling pathway involving neurotrophic factors, can activate the anti-apoptotic and Parkinson’s disease. Both intrinsic and extrinsic factors, including neurotrophic factors, can activate the anti-apoptotic process to rescue neuronal cell death. The signaling pathway leading to cell survival remains unresolved. In this regard, NCS-1 was found to be a novel Ca²⁺-dependent survival-promoting factor upregulated in injured neurons (Nakamura et al., 2006), based on the following observations. (1) NCS-1 expression increases in injured neurons; (2) NCS-1 overexpression diminished various stress-induced neuronal cell death in culture; and (3) the dominant negative EF-hand NCS-1 mutant (E120Q) accelerated cell death. Mechanistically, the expression level of NCS-1 in neuron is increased by GDNF, a neurotrophic factor upregulated by neuronal injury, and NCS-1 mediates GDNF survival signaling via the activation of the Akt pathway.

Role in Stress Tolerance in Cardiomyocytes
Not only in neurons, NCS-1 also plays a key role in protecting cardiomyocytes against stress through the activation of mitochondrial detoxification pathways (Nakamura et al., 2016). Excessive stress induces cytosolic Ca²⁺ overload and cell death. In contrast, mild forms of stress lead to physiologically relevant changes in Ca²⁺, which activate Ca²⁺-dependent survival pathways by binding to Ca²⁺-sensor proteins. As one such protein, NCS-1 was found to play important roles in Ca²⁺-dependent survival signaling. Ncs1⁻/⁻ myocytes were more susceptible to oxidative and metabolic stress, and cellular ATP levels, mitochondrial respiration and biosynthesis were significantly reduced in these cells. In wild-type myocytes, mild oxidative stress increased the mitochondrial proton leak, which exerted a protective effect by inhibiting the production of reactive oxygen species. However, this response was diminished in Ncs1⁻/⁻ cardiomyocytes, thus resulting in cell death. Similar susceptibility was also observed in Ncs1⁻/⁻ hearts subjected to ischemia-reperfusion injury. In these hearts, molecules regulating Ca²⁺-dependent survival pathways, such as Akt and PGC-1α, which promote mitochondrial biogenesis and function, were significantly downregulated compared to wild-type hearts. These data demonstrate a novel role of NCS-1 that contributes to stress tolerance in cardiomyocytes, partly by the activation of Ca²⁺-dependent survival pathways. NCS-1 may also participate in cardioprotection by mediating receptor-signaling pathways. For example, NCS-1 associates with, and modulates, adenosine receptor activity (Navarro et al., 2012). Given the central role of adenosine in mediating the protective effects of ischemic preconditioning (Cohen and Downey, 2008), it is entirely possible that the cardioprotective effects of NCS-1 is partially mediated by this pathway.

CONCLUSION
Recently, studies have elucidated new roles of NCS-1 in physiology and pathophysiology. In this review, we have mainly focused on NCS-1 in the neuronal system and heart. Our particular interest is the emerging theme that NCS-1 directly regulates the function of several ion channels that permeate Ca²⁺ (e.g., several types of voltage-gated Ca²⁺ channels, ionotropic dopamine receptors, and InsP₃Rs), suggesting a general role of Ca²⁺ influx via the channel that binds to NCS-1 and consequently regulates channel functions and/or downstream Ca²⁺-dependent signaling, which affect various neuronal and cardiac functions. Furthermore, many established roles of NCS-1 are related to protective responses of cells against exogenous stress that leads to mild increases in cytosolic Ca²⁺. This suggest
that intracellular Ca$^{2+}$ as a determinant of cell survival and cell death, and Ca$^{2+}$-sensor proteins, such as NCS-1, may serve as a switch to proceed the signal. We believe that this review provides intriguing observations and compels researchers to conduct detailed investigations and extend their studies on NCS-1 and its important regulatory proteins.

**AUTHOR CONTRIBUTIONS**

TN conducted most part of research, wrote, organized, and finalized the article. SN did some experiments and wrote some part of the article. SW contributed to the discussion on all part of the study and wrote some part of the manuscript. SN and SW wrote and edited some parts of the article.
