ABSTRACT

Even though only a handful of sub-stellar companions have been found via direct imaging, each of these discoveries has had a tremendous impact on our understanding of the star formation process and the physics of cool atmospheres. Young stars are prime targets for direct imaging searches for planets and brown dwarfs due to the favorable brightness contrast expected at such ages and also because it is often possible to derive relatively good age estimates for these primaries. Here we present the direct imaging discovery of HD 284149 b, a 18–50 $M_{\text{Jup}}$ companion at a projected separation of 400 AU from a young (25$^{+25}_{-10}$ Myr) F8 star, with which it shares common proper motion.

Key words: brown dwarfs – instrumentation: adaptive optics – methods: observational – planetary systems – stars: individual (HD 284149) – stars: pre-main sequence

1. INTRODUCTION

In recent years, the rapid improvement of high-contrast imaging instrumentation and techniques have led to the discovery of a number of wide sub-stellar companions to nearby young stars, down to planetary mass (e.g., Chauvin et al. 2005; Luhman et al. 2006; Marois et al. 2008, 2010; Lagrange et al. 2009; Currie et al. 2014). Several of these discoveries, such as AB Pic b (Chauvin et al. 2005), HN Peg B (Luhman et al. 2007), 1RXS J1609 b (Lafreni`ere et al. 2008, 2010), HIP 78530 b (Lafreni`ere et al. 2011) and the recently discovered HD 106906 b (Bailey et al. 2014) and ROXS 42B b (Currie et al. 2014), have mass ratios with respect to their parent stars of only $\gtrsim 1\%$ and seriously challenge the current planet formation paradigm. In particular, their large separations are hard to explain and suggest they might be extreme outcomes of their underlying formation mechanism, regardless of whether it is based on core accretion or disk instability.

Our previous survey of 91 stars in the USco region (Lafreni`ere et al. 2014) implies a frequency of wide companion for such regions of 4%–5%, in agreement with other studies (Ireland et al. 2011). This suggests a frequency of wide companions in star forming regions comparable to the values for young moving groups or the field, reported for example by Lafreni`ere et al. (2007), Metchev & Hillenbrand (2009), and Chauvin et al. (2010).

Most recently we also confirmed three new companions with masses of $\sim 40–100 M_{\text{Jup}}$ and separations of $\sim 40–230$ AU in the Scorpius–Centaurus (Sco-Cen) region (Janson et al. 2012b). These companions represent an interesting intermediate between stellar companions and the $\sim 10–20 M_{\text{Jup}}$ ones described above in the Upper Scorpius (USco) region. The existence of such a seemingly continuous population might imply that binary formation extends all the way down to planetary masses for wide separations, or at least that mass alone is not a clear-cut diagnostic for distinguishing between formation mechanisms. In order to further address these issues, we conducted a survey of 74 stars in the Taurus star forming region with ALTAIR/NIRI (Herriot et al. 2000; Hodapp et al. 2003). The results of the full survey will be presented in a dedicated paper (Daemgen et al. 2014). Here we present the discovery of a 18–50 $M_{\text{Jup}}$ companion at a projected separation of $\sim 400$ AU from the F8 star HD 284149. A dedicated analysis of the host properties is also presented in Section 3, addressing the question of its questionable Taurus membership.

2. OBSERVATIONS AND DATA REDUCTION

HD 284149 was observed during six epochs between 2011 October and 2014 March on Gemini North with the adaptive-optics assisted NIRI instrument (Hodapp et al. 2003) in the $J$, $H$, and $K_s$ bands. The f/32 camera provided a sampling of 21.9 mas/pixel and a field of view of $22` \times 22`$. Total integration times varied between 9 s ($J$) and $\sim 7$ s ($K_s$) and were taken as a series of coadds in a five-point dither pattern to increase dynamic range and allow sky subtraction. The details of the observing times for each epoch, together with the mean airmass and seeing at each observing date, are reported in Table 2. After subtraction of a striping pattern frequently observed in Niri images, all images were flat fielded, bad pixel corrected, and sky subtracted. The field distortion was corrected as described in Lafreni`ere et al. (2014) who determine a residual astrometric uncertainty of 15 mas, 25 mas, and 50 mas at radii 4`, 8`, and 12` from the center, respectively.

The left panel of Figure 1 shows one of the fully reduced images of HD 284149 and its companion obtained with NIRI in 2012B. The achieved full width at half maximum of the point spread function (PSF) is 0`08, and the companion, at a separation of 3`7 is detected at $\gtrsim 14\sigma$. As part of our survey for faint companions in Taurus (Daemgen et al. 2014), we also obtained deep exposures of HD 284149 in $H$ and $J$ band, which confirm the presence of the companion with high S/N $> 200$. These observations, however, saturate the central star and render the relative astrometry and photometry less precise than in the
smaller amounts of reddening are indicated by the about 0.05–0.08 mag for a G1 and F8 star, respectively. Slightly distance of the star. The trigonometric parallax from van Leeuwen colors. Such amount of reddening is not unexpected at the dis-

6 In order to reduce the impact of possible binarity on the space velocity, we lower signal-to-noise ratio (S/N) images analyzed here, and are not further used.

3. HOST STAR PROPERTIES

HD 284149 was included among the members of Taurus–Auriga association by Wichmann et al. (1996), but it is not considered in the compilations by Kenyon et al. (2008) and Esplin et al. (2014). Therefore, a re-assessment of the stellar properties is needed. HD 284149 was classified as F8 by Nguyen et al. (2012) and G1 by Wichmann et al. (2000).

A young age of the star is supported by the large lithium EW (Wichmann et al. 2000), the large X-ray luminosity as revealed by ROSAT, the photometric variability and fast rotation (a period of 1.079 days is reported by Grankin et al. 2007). The short-

term radial velocity (RV) monitoring by Nguyen et al. (2012) was able to exclude the possibility of a tidally locked binary. However with a 3 km s\(^{-1}\) difference between mean RV from Wichmann et al. (2000) and Nguyen et al. (2012) being about 3 km s\(^{-1}\), a binarity with periods of months or years cannot be excluded.\(^6\)

From the G1-F8 spectral classification, an effective temperature of 5970–6100 K is derived following Pecaut & Mamajek (2013). Photometric colors are broadly consistent with such temperatures, with a detailed comparison hampered by observational scatter (e.g., peak-to valley differences larger than 0.2 mag in \(V\) band), possibly linked to the photometric variability of the star. Adopting the \(V\) magnitude from ASAS (9.653 ± 0.060), the \(V - K_s\) color is 1.55 mag. Comparison with the pre-main sequence (pre-MS) intrinsic colors of young stars by Pecaut & Mamajek (2013) suggests a reddening \(E(B-V)\) of about 0.05–0.08 mag for a G1 and F8 star, respectively. Slightly smaller amounts of reddening are indicated by the \(B-V\) and \(V-I\) colors. Such amount of reddening is not unexpected at the distance of the star. The trigonometric parallax from van Leeuwen (2007) is 9.24 ± 1.58 mas. A comparison with members of young moving groups (MGs; see left panel of Figure 2) indicates that the lithium equivalent width of HD 284149 (208 mÅ; Wichmann et al. 2000) is comparable with that of members of \(\beta\) Pic, Tuc-Hor, Columba and Carina moving groups of similar temperatures, and clearly above that of Pleiades open cluster and AB Dor moving group. A similar result is obtained for a comparison of the X-ray luminosity (\(\log L_X/L_{bol} = -3.3\) for HD 284149).

The position of HD 284149 on an H-R diagram (see right panel of Figure 2) is close to the 25 Myr isochrone using the theoretical models by Bressan et al. (2012), with ages between 15 to 100 Myr also compatible with the data. This isochronal age is on average older than that obtained by other authors (14–16 Myr, Wichmann et al. 2000; Palla & Stahler 2002) because of the revision in the trigonometric parallax, with respect to the value reported in the Hipparcos catalog (Perryman et al. 1997).

The resulting kinematic parameters, adopting the van Leeuwen (2007) parallax and proper motion and the mean of the RVs obtained by Wichmann et al. (2000) and Nguyen et al. (2012), are \(U = -12.3\) km s\(^{-1}\), \(V = -6.4\) km s\(^{-1}\), and \(W = -8.8\) km s\(^{-1}\). This is similar to that of the Octans association discussed in Torres et al. (2008), whose proposed members are however all very far from HD 284149 on the sky. Recently Zuckerman et al. (2013) identified an additional group of young stars with similar kinematics to the Octans association but with a smaller distance from the Sun and a different sky distribution, labeled as Octans-Near. While the link between Octans and Octans-Near groups and the existence of the latter as a true moving group deserves further investigation, we note that one of the Octans–Near proposed members, HIP 19496, is separated on the sky by about 5 deg from HD 284189, it has a comparable distance (98 versus 108 pc), and the space velocities of the two stars differ by just 2.7 km s\(^{-1}\). Zuckerman et al. (2013) estimate an age of 30 Myr for HIP 19496, similar to our determination for HD 284189.

In summary, HD 284149 is significantly older than the bulk of the Taurus–Auriga association. Membership is still possible in case of earlier start of star formation in the outer regions of the association (Palla & Stahler 2002). Independently of

the Tau-Aur membership, the Li EW well above the Pleiades locus coupled with the position on H-R diagram above ZAMS and other age diagnostics indicate an age of about 25 Myr, with minimum and maximum values of about 15 and 50 Myr respectively. A summary of the stellar parameters is given in Table 1.

4. COMPANION PROPERTIES

The relative position of HD 284149 and its companion were determined with PSF photometry using daophot in IRAF. The bright star HD 284149 was used as PSF reference to obtain relative photometry and astrometry of the companion. Statistical uncertainties were inferred from the rms noise between the individual dither exposures for each epoch and filter. Systematic flux uncertainties are estimated from the residuals after PSF subtraction to be $\lesssim 5\%$, and systematic astrometric uncertainties are dominated by the uncertainty of the distortion correction at the position of HD 284149b of $\lesssim 15$ mas. The resulting astrometry and photometry are listed in Table 2, while a summary of the derived properties is given in Table 1.

The right panel of Figure 1 shows the relative change of separation and position angle of the companion between our previous observations (filled right-facing triangle) with respect to the most recent one (filled circle). We conclude that the point source we imaged is consistent with a co-moving companion at $\sim 400$ AU from HD284149 with $>99\%$ confidence according to a $\chi^2$ test. As discussed in Section 3, the age of this system is controversial, as it appears to be older than other members of the Taurus association. With an adopted age of $25^{+25}_{-10}$ Myr, the $K_s$ brightness of the companion suggests a mass of $32^{+18}_{-14} M_{Jup}$, according to the DUSTY models by Chabrier et al. (2000). Using the DUSTY models by Chabrier et al. (2000) we derived an effective temperature of $2337^{+95}_{-182}$ K. Together with the color measurements ($J-H \sim 0.8$, $H-K \sim 0.4$) this suggests a spectral type between M8 and L1 (see, e.g., Pecaut & Mamajek 2013 and http://www.pas.rochester.edu/~emamajek/ for the extended table), but further measurements are required to better constrain this.

5. DISCUSSION AND CONCLUSIONS

We presented here the detection of a substellar ($32 M_{Jup}$ assuming an age of 25 Myr, see Figure 3 (left) and Table 1) companion orbiting the young star HD 284149 at a separation of $\sim 400$ AU.

Figure 3 shows a comparison of HD 284149 mass-ratio and separation with the values of the planetary companions found by RVs and transit methods, as well as other directly imaged planetary and brown dwarf companions. The group of objects with separation $<100$ AU and mass ratio $<0.01$ seems to be well separated from the one including companions with larger
separation and mass ratio, suggesting that different formation mechanisms could be at play. The small mass ratio of the first group might suggest planet-like formation, but objects with similar mass-ratios at larger separations are difficult to explain.

HD 284149b shows very similar properties to objects like ROXs 42Bb or AB Pic b which, as suggested by Currie et al. (2014), places it between the bona-fide planets and the lowest mass brown dwarfs imaged so far. Together with these and other companions of similar mass and separation, such as HN Peg B and HD 106906, HD 284149b represents a challenge for our understanding of the formation of low-mass companions at very wide separations. The high mass ratio of these systems might suggest a planet-like origin, but at the same time, their estimated mass is well above the deuterium burning limit, suggesting a stellar-like formation.

The existence of such companions suggests that mass ratio alone is not sufficient to distinguish between planet-like and star-like formation, at least for wide companions (see also Janson et al. 2012a).

Finally, the findings of dedicated RV campaigns around young stars seem to suggest a paucity of close-in planetary companions around these targets. Only few close-in companions have been detected around young early-G and F-type stars, such as HD 70573 (Setiawan et al. 2007) and HD 113337 (Borgniet et al. 2014). Their small number seems to imply a lower frequency of such companions if compared to the more massive, more distant ones such as HD 284149B. If confirmed, this could suggest that multiple planet formation mechanisms are at play around these objects.

The object brightness and separation makes HD 284149b a very well suited target for detailed characterization of both the host star and the companion. Efforts toward this direction are already under way and will be presented in further publications.
