Abstract

This paper is concerned with learning categorial grammars in Gold’s model. In contrast to \( k \)-valued classical categorial grammars, \( k \)-valued Lambek grammars are not learnable from strings. This result was shown for several variants but the question was left open for the weakest one, the non-associative variant \( NL \).

We show that the class of rigid and \( k \)-valued \( NL \) grammars is unlearnable from strings, for each \( k \); this result is obtained by a specific construction of a limit point in the considered class, that does not use product operator.

Another interest of our construction is that it provides limit points for the whole hierarchy of Lambek grammars, including the recent pregroup grammars.

Such a result aims at clarifying the possible directions for future learning algorithms: it expresses the difficulty of learning categorial grammars from strings and the need for an adequate structure on examples.

1 Introduction

Categorial grammars (Bar-Hillel, 1953) and Lambek grammars (Lambek, 1958; Lambek, 1961) have been studied in the field of natural language processing. They are well adapted to learning perspectives since they are completely lexicalized and an actual way of research is to determine the sub-classes of such grammars that remain learnable in the sense of Gold (Gold, 1967).

We recall that learning here consists to define an algorithm on a finite set of sentences that converge to obtain a grammar in the class that generates the examples. Let \( \mathcal{G} \) be a class of grammars, that we wish to learn from positive examples. Formally, let \( \mathcal{L}(G) \) denote the language associated with grammar \( G \), and let \( V \) be a given alphabet, a learning algorithm is a function \( \phi \) from finite sets of words in \( V^* \) to \( \mathcal{G} \), such that for all \( G \in \mathcal{G} \) with \( \mathcal{L}(G) = \langle e_1, \ldots, e_n \rangle \) there exists a grammar \( G' \in \mathcal{G} \) and there exists \( n_0 \in \mathbb{N} \) such that: \( \forall n > n_0 \phi(\langle e_1, \ldots, e_n \rangle) = G' \in \mathcal{G} \) with \( \mathcal{L}(G') = \mathcal{L}(G) \).

After pessimistic unlearnability results in (Gold, 1967), learnability of non trivial classes has been proved in (Angluin, 1980) and (Shinohara, 1990). Recent works from (Kanazawa, 1998) and (Nicolas, 1999) following (Buszkowski and Penn, 1990) have answered the problem for different sub-classes of classical categorial grammars (we recall that the whole class of classical categorial grammars is equivalent to context free grammars; the same holds for the class of Lambek grammars (Pentus, 1993) that is thus not learnable in Gold’s model).

The extension of such results for Lambek grammars is an interesting challenge that is addressed by works on logic types from (Dudau-Sofronie et al., 2001) (these grammars enjoy a direct link with Montague semantics), learning from structures in (Rector and Bonato, September 2001), complexity results from (Florêncio, 2002) or unlearnability results from...
In this paper, we consider the following question: is the non-associative variant NL of k-valued Lambek grammars learnable from strings; we answer by constructing a limit point for this class. Our construction is in some sense more complex than those for the other systems since they do not directly translate as limit point in the more restricted system NL.

The paper is organized as follows. Section 2 gives some background knowledge on three main aspects: Lambek categorial grammars; learning in Gold’s model; Lambek pregroup grammars that we use later as models in some proofs. Section 3 then presents our main result on NL (NL denotes non-associative Lambek grammars not allowing empty sequence); after a construction overview, we discuss some corollaries and then provide the details of proof. Section 4 concludes.

2 Background

2.1 Categorial Grammars

The reader not familiar with Lambek Calculus and its non-associative version will find nice presentations in the first ones written by Lambek (Lambek, 1958; Lambek, 1961) or more recently in (Kandulska, 1988; Aarts and Trautwein, 1995; Buszkowski, 1997; Moortgat, 1997; de Groote, 1999; de Groote and Lamarche, 2002).

The types $Tp$, or formulas, are generated from a set of primitive types $Pr$, or atomic formulas by three binary connectives “/” (over), “\” (under) and “•” (product): $Tp := Pr | Tp \cdot Tp | Tp / Tp | Tp \cdot Tp$. As a logical system, we use a Gentzen-style sequent presentation. A sequent $\Gamma \vdash A$ is composed of a sequence of formulas $\Gamma$ which is the antecedent configuration and a succedent formula $A$.

Let $\Sigma$ be a fixed alphabet. A categorial grammar over $\Sigma$ is a finite relation $G$ between $\Sigma$ and $Tp$. If $c, A \in G$, we say that $G$ assigns $A$ to $c$, and we write $G : c \mapsto A$.

### 2.1.1 Lambek Derivation $\vdash_L$

The relation $\vdash_L$ is the smallest relation $\vdash$ between $Tp^*$ and $Tp$, such that for all $\Gamma, \Gamma' \in Tp^+$, $\Delta, \Delta' \in Tp$ and for all $A, B, C \in Tp$:

\[
\Delta, A, \Delta' \vdash C \quad \Gamma \vdash A \quad \Delta, \Gamma, \Delta' \vdash C \quad (Cut) \quad A \vdash A \quad (Id)
\]

\[
\Delta, B \vdash A, \Delta, \Delta' \vdash C / L \quad \Gamma \vdash A \quad \Delta, B / A, \Gamma, \Delta' \vdash C \quad \Gamma \vdash B / A \quad R
\]

\[
\Delta, \Delta' \vdash C \quad \Gamma \vdash A \quad \Delta, A \vdash B, \Delta, \Delta' \vdash C \quad \Delta, A \vdash B, \Delta' \vdash C \quad \Delta, A \vdash B \quad R
\]

\[
\Delta, A \vdash B, \Delta, \Delta' \vdash C \quad \Delta, A \vdash B \quad \Delta, B \vdash A, \Delta' \vdash C \quad \Delta, B \vdash A \quad \Delta, \Delta' \vdash C \quad \Delta, A \vdash B \quad \Delta, B \vdash A \quad \Delta, \Delta' \vdash C \quad \Delta, A \vdash B \quad \Delta, B \vdash A \quad \Delta, \Delta' \vdash C \quad \Delta, A \vdash B \quad \Delta, B \vdash A \quad \Delta, \Delta' \vdash C
\]

We write $L_0$ for the Lambek calculus with empty antecedents (left part of the sequent).

### 2.1.2 Non-associative Lambek Derivation $\vdash_{NL}$

In the Gentzen presentation, the derivability relation of $NL$ holds between a term in $S$ and a formula in $Tp$, where the term language is $S := Tp|(S, S)$. Terms in $S$ are also called $G$-terms. A sequent is a pair $(\Gamma, A) \in S \times Tp$. The notation $\Gamma[\Delta]$ represents a $G$-term with a distinguished occurrence of $\Delta$ (with the same position in premise and conclusion of a rule). The relation $\vdash_{NL}$ is the smallest relation $\vdash$ between $S$ and $Tp$, such that for all $\Gamma, \Delta \in S$ and for all $A, B, C \in Tp$:

\[
\Gamma[A] \vdash C \quad \Delta \vdash A \quad (Cut) \quad A \vdash A \quad (Id)
\]

\[
\Delta[\Delta] \vdash C \quad \Gamma[A, \Gamma] \vdash C / L \quad \Gamma \vdash B / A \quad (\Gamma, A) \vdash B 
\]

\[
\Delta[(A, \Delta) \vdash B] \vdash C \quad \Delta[(\Gamma, A \vdash B)] \vdash C \quad \Delta[(A \vdash B)] \vdash C \quad \Gamma \vdash A \quad \Delta \vdash B \quad (\Gamma, \Delta) \vdash (A \vdash B)
\]

We write $NL_0$ for the non-associative Lambek calculus with empty antecedents (left part of the sequent).
2.1.3 Notes

Cut elimination. We recall that cut rule can be eliminated in \( \vdash_L \) and \( \vdash_{NL} \): every derivable sequent has a cut-free derivation.

Type order. The order \( \text{ord}(A) \) of a type \( A \) of \( L \) or \( NL \) is defined by:
\[
\text{ord}(A) = 0 \quad \text{if} \quad A \text{ is a primitive type}
\]
\[
\text{ord}(C_1 / C_2) = \max(\text{ord}(C_1), \text{ord}(C_2) + 1)
\]
\[
\text{ord}(C_1 \setminus C_2) = \max(\text{ord}(C_1) + 1, \text{ord}(C_2))
\]
\[
\text{ord}(C_1 \cdot C_2) = \max(\text{ord}(C_1), \text{ord}(C_2))
\]

2.1.4 Language.

Let \( G \) be a categorial grammar over \( \Sigma \). \( G \) generates a string \( c_1 \ldots c_n \in \Sigma^+ \) iff there are types \( A_1, \ldots, A_n \in T_p \) such that: \( G : c_i \mapsto A_i \quad (1 \leq i \leq n) \) and \( A_1, \ldots, A_n \vdash_L S \). The language of \( G \), written \( \mathcal{L}(G) \), is the set of strings generated by \( G \).

We define similarly \( \mathcal{L}_{L_0}(G) \), \( \mathcal{L}_{NL}(G) \) and \( \mathcal{L}_{NL_0}(G) \) replacing \( \vdash_L \) by \( \vdash_{L_0} \), \( \vdash_{NL} \) and \( \vdash_{NL_0} \) in the sequent where the types are parenthesized in some way.

2.1.5 Notation.

In some sections, we may write simply \( \vdash \) instead of \( \vdash_L, \vdash_{L_0}, \vdash_{NL} \) or \( \vdash_{NL_0} \). We may simply write \( \mathcal{L}(G) \) accordingly.

2.1.6 Rigid and \( k \)-valued Grammars.

Categorial grammars that assign at most \( k \) types to each symbol in the alphabet are called \( k \)-valued grammars; \( 1 \)-valued grammars are also called rigid grammars.

Example 1 Let \( \Sigma_1 = \{ \text{John}, \text{Mary}, \text{likes} \} \) and let \( Pr = \{ S, N \} \) for sentences and nouns respectively.

Let \( G_1 = \{ \text{John} \mapsto N, \text{Mary} \mapsto N, \text{likes} \mapsto N \setminus (S / N) \} \). We get \( (\text{John likes Mary}) \in \mathcal{L}_{NL}(G_1) \) since \((\{N, N \setminus (S / N)\}, N) \vdash_{NL} S \).

\( G_1 \) is a rigid (or \( 1 \)-valued) grammar.

2.2 Learning and Limit Points

We now recall some useful definitions and known properties on learning.

2.2.1 Limit Points

A class \( \mathcal{CL} \) of languages has a limit point if there exists an infinite sequence \( < L_n >_{n \in \mathbb{N}} \) of languages in \( \mathcal{CL} \) and a language \( L \in \mathcal{CL} \) such that:
\[
L_0 \subseteq L_1 \subseteq \ldots \subseteq L_n \subseteq \ldots \quad \text{and} \quad L = \bigcup_{n \in \mathbb{N}} L_n
\]
(\( L \) is a limit point of \( \mathcal{CL} \)).

2.2.2 Limit Points Imply Unlearnability

The following property is important for our purpose. If the languages of the grammars in a class \( G \) have a limit point then the class \( G \) is unlearnable. \(^1\)

2.3 Some Useful Models

For ease of proof, in next section we use two kinds of models that we now recall: free groups and pregroups introduced recently by (Lambek, 1999) as an alternative of existing type grammars.

2.3.1 Free Group Interpretation.

Let \( FG \) denote the free group with generators \( Pr \), operation \( \cdot \) and with neutral element 1. We associate with each formula \( C \) of \( L \) or \( NL \), an element in \( FG \) written \([C]\) as follows:
\[
\begin{align*}
[C] &= A \quad \text{if} \quad A \text{ is a primitive type} \\
[C_1 \setminus C_2] &= [C_1]^{-1} \cdot [C_2] \\
[C_1 / C_2] &= [C_1] \cdot [C_2] \\
[C_1 \cdot C_2] &= [C_1] \cdot [C_2]
\end{align*}
\]

We extend the notation to sequents by:
\[
[C_1, C_2, \ldots, C_n] = [C_1] \cdot [C_2] \cdot \ldots \cdot [C_n]
\]

The following property states that \( FG \) is a model for \( L \) (hence for \( NL \)): if \( \Gamma \vdash_L C \) then \( [\Gamma] =_{FG} [C] \).

2.3.2 Free Pregroup Interpretation

Pregroup. A pregroup is a structure \((P, \leq, l, r, 1)\) such that \((P, \leq, 1)\) is a partially ordered monoid\(^2\) and \( l, r \) are two unary operations on \( P \) that satisfy for all \( a \in P \)
\[
aa^l \leq a \quad \text{and} \quad aa^r \leq 1 \leq a^l a^r.
\]

Free pregroup. Let \((P, \leq)\) be an ordered set of primitive types, \( P^{(Z)} = \{ p^{(i)} | p \in P, i \in \mathbb{Z} \} \) is the set of atomic types and \( T_{(P, \leq)} = (P^{(Z)})^+ = \{ p_1^{(i_1)} \ldots p_n^{(i_n)} | 0 \leq k \leq n, p_k \in P \text{ and } i_k \in \mathbb{Z} \} \) is the set of types. For \( X \) and \( Y \) in \( T_{(P, \leq)} \), \( X \leq Y \) if this relation is deductible in the following system

\[\vdash \]

\[ p, q \in P, n, k \in \mathbb{Z} \text{ and } X, Y, Z \in T_{(P, \leq)} \]:

\[^1\text{This implies that the class has infinite elasticity. A class } \mathcal{CL} \text{ of languages has infinite elasticity if } \exists \ e_i >_{i \in \mathbb{N}} \text{ languages in } \mathcal{CL} \text{ such that } e_i \in L_i \text{ and } \{ e_1, \ldots, e_n \} \subseteq L_{n+1} \text{.}\]

\[^2\text{We briefly recall that a monoid is a structure } (M, \cdot, 1) \text{, such that } \cdot \text{ is associative and has a neutral element } 1 \text{ (forall } x \in M : 1 \cdot x = x \cdot 1 = x \text{). A partially ordered monoid is a monoid } (M, \cdot, 1) \text{ with a partial order } \preceq \text{ that satisfies } \forall a, b, c : a \preceq b \implies c \cdot a \preceq c \cdot b \text{ and } a \cdot c \preceq b \cdot c.\]
\[ X \leq X \quad (Id) \]
\[ X \leq Y \quad Y \leq Z \quad (Cut) \]
\[ XY \leq Z \quad (AL) \]
\[ X \leq YZ \quad (AN) \]
\[ Xp_{(n)}^{(p)}(n+1)Y \leq Z \quad (IND) \]
\[ X \leq \frac{Y}{p_{(n)}^{(p)}}Z \quad (IND) \]
\[ Xq_{(k)}^{(p)}Y \leq Z \quad (IND) \]
\[ X \leq \frac{Y}{q_{(k)}^{(p)}}Z \quad (IND) \]

This construction, proposed by Buskowski, defines a pregroup that extends \( \leq \) on primitive types \( P \) to \( T_{(P, \leq)}^{3} \).

**Cut elimination.** As for \( L \) and \( NL \), cut rule can be eliminated: every derivable inequality has a cut-free derivation.

**Simple free pregroup.** A simple free pregroup is a free pregroup where the order on primitive type is equality.

**Free pregroup interpretation.** Let \( FP \) denotes the simple free pregroup with \( Pr \) as primitive types. We associate with each formula \( C \) of \( L \) or \( NL \), an element in \( FP \) written \( [C] \) as follows:
\[
[A] = A \quad \text{if } A \quad \text{is a primitive type} \\
[C_{1} \cdot C_{2}] = [C_{1}][C_{2}] \\
[C_{1} \cdot C_{2}] = [C_{1}][C_{2}]^{k} \\
[C_{1} \cdot C_{2}] = [C_{1}][C_{2}]^{l} \\

We extend the notation to sequents by:
\[
[A_{1}, \ldots, A_{n}] = [A_{1}] \ldots [A_{n}] \\

The following property states that \( FP \) is a model for \( L \) (hence for \( NL \)): if \( \Gamma \vdash_{L} C \) then \( [\Gamma] \leq_{FP} [C] \).

3 Limit Point Construction

3.1 Method overview and remarks

**Form of grammars.** We define grammars \( G_{n} \) where \( A, B, D_{n} \) and \( E_{n} \) are complex types and \( S \) is the main type of each grammar:
\[
G_{n} = \{ a \mapsto A / B; \quad b \mapsto D_{n}; \quad c \mapsto E_{n} / S \} \\

Some key points.

- We prove that \( \{a^{k}bc \mid 0 \leq k \leq n \} \subseteq \mathcal{L}(G_{n}) \) using the following properties:

3.2 Definition and Main Results

**Definitions of Rigid grammars \( G_{n} \) and \( G_{s} \)**

**Definition 1** Let \( p, q, S, \) three primitive types. We define:
\[
A = D_{0} = E_{0} = q / (p \setminus q) \\
B = p \\
D_{n+1} = (A / B \setminus D_{n}) \\
E_{n+1} = (A / A \setminus E_{n}) \\

Let \( G_{n} = \{ a \mapsto A / B = (q / (p \setminus q)) / p \} \)
Let \( G_{s} = \{ a \mapsto (p / p) \quad b \mapsto p \quad c \mapsto (p \setminus S) \} \)

**Main Properties**

**Proposition 1** (language description)

- \( \mathcal{L}(G_{n}) = \{a^{k}bc \mid 0 \leq k \leq n \} \)
- \( \mathcal{L}(G_{s}) = \{a^{k}bc \mid 0 \leq k \leq n \} \).

From this construction we get a limit point and the following result.

**Proposition 2** (NL-non-learnability) The class of languages of rigid (or \( k \)-valued for an arbitrary \( k \)) non-associative Lambek grammars (not allowing empty sequence and without product) admits a limit point ; the class of rigid (or \( k \)-valued for an arbitrary \( k \)) non-associative Lambek grammars (not allowing empty sequence and without product) is not learnable from strings.
3.3 Details of proof for $G_n$

Lemma
\[ \{a^kb^c \mid 0 \leq k \leq n\} \subseteq \mathcal{L}(G_n) \]

Proof: It is relatively easy to see that for \( 0 \leq k \leq n \), \( a^kb^{c} \in \mathcal{L}(G_n) \). We have to consider (\( (a \cdots (a(a(b)) \cdots)c) \)) and prove the following sequent in \( NL \):

\[ ((A / B), \ldots, ((A / B), \ldots) \)

\[ ((A / B) \cdots 
\]

\[ ((A / A) \cdots \cdot \cdot \cdot ((A / A) \cdots \cdot \cdot \cdot S)) \cdot_{NL} S \]

Models of \( NL \)

For the converse, (for technical reasons and to ease proofs) we use both free group and free pregroup models of \( NL \) since a sequent is valid in \( NL \) only if its interpretation is valid in both models.

Translation in free groups

The free group translation for the types of \( G_n \) is:

\[ [p] = p, [q] = q, [S] = S \]

\[ [x / y] = [x] \cdot [y]^{-1} \cdot [y] \]

\[ [x \cdot y] = [x] \cdot [y] \]

Type-raising disappears by translation:

\[ [x / (y \setminus x)] = [x] \cdot ([y]^{-1} \cdot [x])^{-1} = [y] \]

Thus, we get:

\[ [A] = [A] \cdot [B]^{-1} = pp^{-1} = 1 \]

\[ [D_{n+1}] = [(A / B) \setminus D_n] = [D_0] = p \]

\[ [E_{n+1}] = [(A / A) \setminus E_n] = [E_0] = p \]

Translation in free pregroups

The free pregroup translation for the types of \( G_n \) is:

\[ [p] = p, [q] = q, [S] = S \]

\[ [x / y] = [x] \cdot [y] \]

\[ [y / x] = [y] \cdot [x] \]

\[ [x \cdot y] = [x] \cdot [y] \]

Type-raising translation:

\[ [x / (y \setminus x)] = [x] \cdot ([y]^{-1} \cdot [x])^{-1} = [x] \cdot [y] \]

Thus, we get:

\[ [A] = [D_0] = [E_0] = [q / (p \setminus q)] = qpp \]

\[ [B] = p \]

\[ [A / B] = [A] \cdot [B]^{-1} = pp^{-1} = 1 \]

\[ [D_{n+1}] = [(A / B) \setminus D_n] = [D_0] = p \]

\[ [E_{n+1}] = [(A / A) \setminus E_n] = [E_0] = p \]

\[ [(A / B) \setminus ((A / A) \setminus (A / B)) \setminus \ldots \setminus ((A / B) \setminus A) \cdots) \]

\[ [(A / A) \cdots \cdot \cdot \cdot ((A / A) \cdots \cdot \cdot \cdot S)) \cdot_{NL} S \]

Model of \( NL \)

\[ \mathcal{L}(G_n) \subseteq \{a^kb^{c} \mid 0 \leq k, 0 \leq k', 0 \leq k'' \} \]

Proof: Let \( \tau_n \) denote the type assignment by the rigid grammar \( G_n \). Suppose \( \tau_n(w) \vdash S \), using free groups \( \{\tau_n(w)\} = S \):

- This entails that \( w \) has exactly one occurrence of \( c \) (since \( \forall \tau_n(c) = p^{-1}S \) and the other type images are either 1 or \( p \))
- Then, this entails that \( w \) has exactly one occurrence of \( b \) on the left of the occurrence of \( c \) (since \( \forall \tau_n(c) = p^{-1}S, \tau_n(b) = p \) and \( \tau_n(a) = 1 \))

Lemma

\[ \mathcal{L}(G_n) \subseteq \{a^kb^{c} \mid 0 \leq k \} \]

Proof: Suppose \( \tau_n(w) \vdash S \), using pregroups \( \{\tau_n(w)\} \leq S \). We can write \( w = a^kb^{c} \cdot c^k \cdot c^{k''} \) for some \( k, k', k'' \), such that:

\[ \forall \tau_n(w) = qpp \cdot pp^{k'}qq^{k''}qpp \cdot pp^{k'}qq^{k''}qpp \cdot pp^{k''}k'' \]

For \( q = 1 \), we get:

\[ pp^{k'} \cdot pp^{k'} \cdot pp^{k'} \cdot pp^{k'} \leq S \]

and it yields \( pp^{k'} \cdot pp^{k'} \cdot pp^{k'} \cdot pp^{k'} \leq S \).

We now discuss possible deductions (note that \( pp^{k'} \cdot pp^{k'} \cdot pp^{k'} \leq S \)):

- If \( k' \neq 0 \) and \( k'' \neq 0 \): \( pp^{k'} \cdot pp^{k'} \leq S \) impossible.
- If \( k' = 0 \) and \( k'' \neq 0 \): \( pp^{k'} \cdot pp^{k'} \leq S \) impossible.
- If \( k' = k'' = 0 \): \( w \in \{a^kb^{c} \mid 0 \leq k \} \)

(Final) Lemma

\[ \mathcal{L}(G_n) \subseteq \{a^kb^{c} \mid 0 \leq k \} \]
Proof: Suppose \( \tau_n(w) \vdash S \), using pregroups \( [\tau_n(w)] \leq S \). We can write \( w = a^k bc \) for some \( k \), such that:
\[
[\tau_n(w)] = \underbrace{a^q_{\ldots}a^q}_{n}p_{\ldots}p_{\ldots}pp_{\ldots}qq_{\ldots}pp_{\ldots}qq_{\ldots}S
\]
We use the following property (its proof is in Appendix A) that entails that \( 0 \leq k \leq n \).

(Auxiliary) Lemma:
if \( 1 \) \( X, Y, qq^l, p, pp^r, q r \leq S \)
\[
\text{where } X \in \{pp^l, qq^l\}^* \text{ and } Y \in \{qq^r, pp^r\}^* \\
\text{then } \begin{cases} 
(2) & nbalt(X qq^l) \leq nbalt(qq^r Y) \\
(2bis) & nbalt(X pp^l) \leq nbalt(pp^r Y)
\end{cases}
\]
\( \text{where } nbalt \text{ counts the alternations of } p \text{’s and } q \text{’s sequences (forgetting/dropping their exponents).} \)

3.4 Details of proof for \( G_\ast \)

Lemma
\( \{a^k bc \mid 0 \leq k \} \subseteq \mathcal{L}(G_\ast) \)

Proof: As with \( G_n \), it is relatively easy to see that for \( k \geq 0 \), \( a^k bc \in \mathcal{L}(G_\ast) \). We have to consider \( ((a \cdots (a(b)) \cdots) \cdots) \) and prove the following sequence in \( NL \):
\[
((\underbrace{p / p}_{k}, \ldots, (\underbrace{p / p}_{k}, p) \cdots, (p \setminus S)) \vdash NL S
\]

Lemma
\( \mathcal{L}(G_\ast) \subseteq \{a^k bc \mid 0 \leq k \} \)

Proof: Like for \( w \in G_n \), due to free groups, a word of \( \mathcal{L}(G_\ast) \) has exactly one occurrence of \( c \) and one occurrence of \( b \) on the left of \( c \) (since \( [\tau_n(c)] = p^{-1}S, [\tau_n(b)] = p \) and \( [\tau_n(a)] = 1 \)).

Suppose \( w = a^kba^k \) \( ca^k \) a similar discussion as for \( G_n \) in pregroups, gives \( k' = k'' = 0 \), hence the result. \( \blacksquare \)

3.5 Non-learnability of a Hierarchy of Systems

An interest point of this construction: It provides a limit point for the whole hierarchy of Lambek grammars, and pregroup grammars.

Limit point for pregroups

The translation \([\cdot]\) of \( G_n \) gives a limit point for the simple free pregroup since for \( i \in \{*, 0, 1, 2, \ldots \} \):
\( \tau_i(w) \vdash_{NL} S \iff w \in \mathcal{L}_{NL}(G_i) \) by definition;
\( \tau_i(w) \vdash_{NL} S \) implies \([\tau_i(w)] \leq S \) by models;
\( [\tau_i(w)] \leq S \) implies \( w \in \mathcal{L}_{NL}(G_i) \) from above.

Limit point for \( NL_0 \)

The same grammars and languages work since for \( i \in \{*, 0, 1, 2, \ldots \} \):
\( \tau_i(w) \vdash_{NL} S \iff [\tau_i(w)] \leq S \) from above;
\( \tau_i(w) \vdash_{NL} S \) implies \( \tau_i(w) \vdash_{NL} S \) by hierarchy;
\( \tau_i(w) \vdash_{NL} S \) implies \([\tau_i(w)] \leq S \) by models.

Limit point for \( L \) and \( L_0 \)

The same grammars and languages work since for \( i \in \{*, 0, 1, 2, \ldots \} \):
\( \tau_i(w) \vdash_{NL} S \iff [\tau_i(w)] \leq S \) from above;
\( \tau_i(w) \vdash_{NL} S \) implies \( \tau_i(w) \vdash_{L} S \) using hierarchy;
\( \tau_i(w) \vdash_{L} S \) implies \( \tau_i(w) \vdash_{L_0} S \) using hierarchy;
\( \tau_i(w) \vdash_{L_0} S \) implies \([\tau_i(w)] \leq S \) by models.

To summarize: \( w \in \mathcal{L}_{NL}(G_i) \) iff \([\tau_i(w)] \leq S \) iff \( w \in \mathcal{L}_{NL}(G_i) \) iff \( w \in \mathcal{L}_{L}(G_i) \) iff \( w \in \mathcal{L}_{L_0}(G_i) \)

4 Conclusion and Remarks

Lambek grammars. We have shown that without empty sequence, non-associative Lambek rigid grammars are not learnable from strings. With this result, the whole landscape of Lambek-like rigid grammars (or \( k \)-valued for an arbitrary \( k \)) is now described as for the learnability question (from strings, in Gold’s model).

Non-learnability for subclasses. Our construct is of order 5 and does not use the product operator. Thus, we have the following corollaries:

- Restricted connectives: \( k \)-valued \( NL, NL_0, L \) and \( L_0 \) grammars \( \text{without product} \) are not learnable from strings.
- Restricted type order:
  - \( k \)-valued free pregroup grammars with types \( \text{not greater than order } 5 \) are not learnable from strings.\(^4\)
- \( k \)-valued free pregroup grammars with types \( \text{not greater than order } 1 \) are not learnable from strings.\(^5\)

The learnability question may still be raised for \( NL \) grammars of order lower than 5.

\(^4\)Even less for some systems. For example in \( L_0 \), all \( E_\alpha \) collapse to \( A \)
\(^5\)The order of a type \( p_1^{i_1} \cdots p_k^{i_k} \) is the maximum of the absolute value of the exponents: \( \max(\lvert i_1 \rvert, \ldots, \lvert i_k \rvert) \).
Special learnable subclasses. Note that however, we get specific learnable subclasses of $k$-valued grammars when we consider $NL$, $NL_0$, $L$ or $L_0$ without product and we bind the order of types in grammars to be not greater than 1. This holds for all variants of Lambek grammars as a corollary of the equivalence between generation in classical categorial grammars and in Lambek systems for grammars with such product-free types (Buszkowski, 2001).

Restriction on types. An interesting perspective for learnability results might be to introduce reasonable restrictions on types. From what we have seen, the order of type alone (order 1 excepted) does not seem to be an appropriate measure in that context.

Structured examples. These results also indicate the necessity of using structured examples as input of learning algorithms. What intermediate structure should then be taken as a good alternative between insufficient structures (strings) and linguistic unrealistic structures (full proof tree structures) remains an interesting challenge.

Appendix A. Proof of Auxiliary Lemma

(Auxiliary) Lemma:

if \((1)\) \(XY qq' pp' qq' S \leq S\)

where \(X \in \{pp', qq'\}^*\) and \(Y \in \{qq', pp'\}^*\)

then \(\begin{align*}
(2) & \text{nbalt}(Xqq') \leq \text{nbalt}(qq'Y) \\
(2bis) & \text{nbalt}(Xpp') \leq \text{nbalt}(pp'Y)
\end{align*}\)

where \(\text{nbalt}\) counts the alternations of \(p\)'s and \(q\)'s sequences (forgetting/dropping their exponents).

Proof: By induction on derivations in Gentzen style presentation of free pregroups (without \(\text{Cut}\)).

Suppose \(XY ZS \leq S\)

where \(\begin{align*}
X \in \{pp', qq'\}^* \\
Y \in \{qq', pp'\}^* \\
Z \in \{(qq' pp' qq'), (qq' qq'), (qq'), 1\}
\end{align*}\)

We show that \(\begin{align*}
\text{nbalt}(Xqq') \leq \text{nbalt}(qq'Y) \\
\text{nbalt}(Xpp') \leq \text{nbalt}(pp'Y)
\end{align*}\)

The last inference rule can only be \((A_L)\)

- Case \((A_L)\) on \(X\): The antecedent is \(XY' ZS \leq S\) where \(Y\) is obtained from \(Y'\) by insertion (in fact insertion of \(pp'\) or \(qq'\)), such that \(Y' \in \{pp', qq'\}^*\). Therefore the induction applies \(\text{nbalt}(Xqq') \leq \text{nbalt}(qq'Y')\) and \(\text{nbalt}(qq'Y') \geq \text{nbalt}(qq''Y')\) (similar for \(p\)) hence the result.

- Case \((A_L)\) on \(Z\) (\(Z\) non empty):
  - if \(Z = (qq' pp' qq')\) the antecedent is \(XY Z'S \leq S\), where \(Z' = qq''\).
  - if \(Z = (qq' qq')\) the antecedent is \(XY Z'S \leq S\), where \(Z' = \epsilon\).

In all three cases the hypothesis applies to \(XY Z'\) and gives the relationship between \(X\) and \(Y\).

- case \((A_L)\) between \(X\) and \(Y\): Either \(X = X'' qq'\) and \(Y = qq' Y''\) or \(X = X'' pp'\) and \(Y = pp' Y''\).

In the \(q\) case, the last inference step is the introduction of \(q\) \(q\):

\[
\frac{X''qq'Y'' ZS \leq S}{X''qq'qq'Y'' ZS \leq S}
\]

We now detail the \(q\) case. The antecedent can be rewritten as \(X'' Y ZS \leq S\) and we have:

\[
\begin{align*}
\text{nbalt}(Xqq') &= \text{nbalt}(X''qq'qq') \\
&= \text{nbalt}(X''qq') \\
\text{nbalt}(Xpp') &= \text{nbalt}(X''qq'pp') \\
&= 1 + \text{nbalt}(X''qq') \\
\text{nbalt}(qq'Y') &= \text{nbalt}(qq'qq'Y'') \\
&= \text{nbalt}(qq'Y'') \\
\text{nbalt}(pp'Y') &= \text{nbalt}(pp'qq'Y'') \\
&= 1 + \text{nbalt}(qq'Y'')
\end{align*}
\]

We can apply the induction hypothesis to \(X'' Y ZS \leq S\) and get (ii):

\[
\text{nbalt}(X''qq') \leq \text{nbalt}(qq'Y')
\]

Finally from (i) (ii) and the induction hypothesis:

\[
\begin{align*}
\text{nbalt}(Xqq') &= \text{nbalt}(X''qq') \\
&\leq \text{nbalt}(qq'Y') \\
\text{nbalt}(Xpp') &= 1 + \text{nbalt}(X''qq') \\
&\leq 1 + \text{nbalt}(qq'Y') \\
&= 1 + \text{nbalt}(qq'qq'Y'') \\
&= 1 + \text{nbalt}(qq'Y'') \\
&= \text{nbalt}(pp'Y')
\end{align*}
\]

The second case with \(p\) instead of \(q\) is similar.
