ABSTRACT

Objective: Maturity level of dendritic cells (DC) plays a pivotal role in initiating and regulating autoimmunity. In Graves’ disease (GD), DCs have more vigorous immune responses than those in healthy controls. Our previous study demonstrated immunoregulatory effects of in vitro 1,25-D3 on the maturation of DC in GD patients. This study aims to evaluate the effect of oral alfacalcidol (1α-D3) on DC maturation in GD patients.

Methods: 25 GD patients with thyrotoxicosis were divided into 2 groups: 12 GD patients receiving oral 1α-D3 and 13 GD patients receiving placebo, in addition to the treatment of propylthiouracil. Comparison of DC maturation was performed before and after the oral 1α-D3. DC maturation was evaluated based on the expression of DC markers (HLA-DR, CD80, CD40, CD83, CD14, and CD206) and the ratio of cytokines interleukin-12 (IL-12)/IL-10.

Results: After 8 weeks, 8 out of 12 GD patients in the treatment group and 6 out of 13 GD patients in the placebo group still had high fT4 level. The expression of CD80 decreased (p=0.48) and CD206 increased (p=0.47) insignificantly among treatment group. The IL-12/IL-10 ratio decreased along with the improvement of fT4 level in both groups. No difference in the IL-12/IL-10 ratio between treatment and placebo group.

Conclusion: The effects of oral 1α-D3 on DC maturation of GD patients have not been clearly demonstrated in this study yet.

Keywords: Vitamin D, Graves’ disease, Dendritic cells.
Endocrinology Department of Dr. Cipto Mangunkusumo Hospital in Jakarta, Indonesia. The diagnosis of GD was made based on clinical manifestation (tachycardia, fine tremor, excessive sweat, diffuse struma, and ophthalmopathy) and laboratory data (low thyroid stimulating hormone [TSH] level, increased fT4 level, and positive thyroid receptor antibody [TRAb]). Patients who took vitamin D supplementation were pregnant or had comorbidities, i.e., diabetes mellitus (DM), chronic kidney disease, and other autoimmune diseases were excluded from the study. Out of 29 patients, 25 patients completed the study, while 4 patients were unable to complete the study due to laboratory technical problems.

This is a double-blinded, randomized clinical trial (RCT) study. A 4-block randomization was performed in 25 GD patients to categorize them into two groups, i.e., the treatment and placebo group. There were 12 GD patients in the treatment group who received propylthiouracil (PTU) 300 mg daily with supplementation of 1α-D3 at dose of 1.5 mcg once daily for 8 weeks; while 13 GD patients in the placebo groups received PTU 300 mg daily and placebo tablets for 8 weeks (Fig. 1).

The patients were scheduled to have hospital visits every two weeks, and the responsible physician evaluated the clinical and laboratory data. All patients gave their informed consent. The study received approval from the Ethics Committee of Faculty of Medicine, Universitas Indonesia no. 489/H2.F1/ETIK/2014.

Biological materials and measurements

After randomization, blood specimens were collected from venous blood at certain times; then underwent centrifugation. The serum was stored at −80°C for laboratory evaluation, and the rests were processed for MDDC cultures. Laboratory evaluation consists of vitamin 25-D3 (Euroimmun) and TRAb (DRG) level before supplementation as well as TSH and fT4 (ROCHE) level before supplementation, at week 4 and week 8 (after supplementation).

MDDC culture: Mo-DC differentiation

MDDC cultures were performed before and after supplementation. The isolation of PBMC and monocytes followed by lipopolysaccharide (LPS) stimulation was done based on the method that has been performed by Budiyati et al. [22]. The isolation of PBMC was conducted through density differences using Ficoll-Paque premium (GE Healthcare). The specimens were dissolved in the Roswell Park Memorial Institute (RPMI) medium at cell density of 1×10^6/ml. Isolation of monocytes was performed using the adherence method. One ml of DC culture media (DCM) was added after the monocytes adhered to the base of the plate. DCM consists of RPMI 1640 medium, 10% fetal bovine serum (Gibco), 800 U/ml of Granulocyte-macrophage colony-stimulating factor (BD Bioscience Pharmingen), and 1000 U/ml of IL-4 (BD Bioscience Pharmingen). At the end of those procedures, the cells then were incubated at 37°C with CO2 5% for the next 5 days.

MDDC culture: DC maturation and harvesting

Additional 500 ng LPS was added (Sigma-Aldrich) to cultures on the fifth day (D5), and the incubation was then continued for further 2 days. After cell harvesting and separation procedures from the supernatant, the cells can be processed for monoclonal antibody staining, while the supernatant was stored at −20°C for evaluating IL-12 and IL-10 cytokines.

Flow cytometry analysis

The flow cytometry analysis was operated using fluorescence-activated cell sorting (FACS) Calibur (BD Biosciences). The fluorochrome-conjugated antibodies (BD Biosciences Pharmingen) used in flow cytometry technique are HLA-DR fluorescein isothiocyanate (FITC) (G46-6, mouse IgG2aκ), CD40 phycoerythrin (PE) (5C3, mouse IgG1κ), CD80 PE-Cyanine5 (PECy5) (L307,4, mouse IgG1κ), CD83 PECy5 (HB15e, mouse IgG1κ), CD206 PE (19,2, mouse IgG1κ), and CD14 FITC (MISE2, mouse IgG2aκ).

The expression of HLA-DR, CD80, CD40, and CD206 were presented in the form of mean fluorescence intensities, while the expression of CD14

Fig. 1: Flow diagram of the randomization
and CD83 were presented in numbers of positive cells. Measurement of cytokine levels (IL-12 and IL-10) was done using Human IL-12 p70 (Quantikine HS ELISA Kit - R&D Systems kit) and Human IL-10 (Quantikine ELISA Kit - R&D Systems).

Statistical analysis
Data were analyzed following per-protocol analysis and presented in mean value ± standard deviation when they have normal distribution and in median value (minimum and maximum value) when they did not have normal distribution. The evaluation of mean or median value for DC marker expression and ratio of IL-12/IL-10 cytokines between before and after supplementation in the treatment and placebo group were carried out using paired t-test when the data had normal distribution and using Wilcoxon test when the data were not normally distributed.

RESULTS
Subject characteristics can be seen in Table 1.
Data are presented in mean value ± SD when they were normally distributed and in median value (minimum and maximum value) when they did not have normal distribution.

Following the randomization, there were two study groups (the treatment and placebo group), which had similar baseline characteristics (p>0.05).

Effects of in vivo 1α-D3 on the expression of DC markers and the ratio of cytokines IL-12/IL-10 in MDDC cultures of GD patients
The effects of in vivo 1α-D3 supplementation on DC maturation were evaluated by comparing each expression of DC marker in the MDDC culture before and after 8-week supplementation. The expression of CD80 on the 7th day of MDDC culture was lower in the treatment group (p=0.48) after supplementation; while in the placebo group, there was an increase (p=0.22). The expression of CD206 on the 7th day of MDDC culture increased in the treatment group (p=0.47); while in the placebo group, it decreased (p=0.18) (Fig. 2). Both CD40 and CD83 expression in both groups increased insignificantly, while the expression of CD14 decreased insignificantly in both groups. Following 8-week supplementation, the ratio of IL-12/IL-10 levels reduced insignificantly in both groups (p=0.53 and p=0.08).

Effects of oral 1α-D3 on fT4 level in GD patients
As many 8 out of 12 GD patients in treatment group and 6 out of 13 GD patients in placebo group still had high fT4 level. Both groups had lower thyroid level (fT4) after 8-week supplementation (3.29±2.05 vs. 2.88±3.01; p=0.34). The percentage of lower fT4 level in both groups were not different (58.49 (0.00-89.33 vs. 76.05-88.16); p=0.77) (Fig. 3).

DISCUSSION
DC has a significant role in initiating and maintaining the autoimmune response [2]. DC maturation process is influenced by genetic and environmental factors. One of the environmental factors contributing to DC maturation is vitamin D. As an immunomodulator; vitamin D regulates several innate and adaptive immune responses found in autoimmune diseases, including inhibition of DC maturation [23]. This study reveals further knowledge regarding the immunoregulatory effect of vitamin D, mainly on inhibition of DC maturation in GD patients. This is the first study reporting the effect of oral vitamin D on inhibition of DC maturation in GD patients.

The mean value of fT4 in 25-D3 level in GD patients of our study was 25±6.62 ng/ml. This value is higher than a value reported in Japan. Yasuda et al. [19] reported the mean value of vitamin 25-D3 level in GD patients was 14.5±2.9 ng/ml in non-remission versus 18.2±5.1 ng/ml in remission group. About 76% patients in our study still had vitamin D insufficiency (<30 ng/ml). This finding is similar to studies on other autoimmune diseases [24].

Effects of in vivo 1α-D3 on the expression of DC markers in MDDC cultures of GD patients
This study design refers to a study conducted by Kawakami-Tani et al. which reported that there is a greater reduction of fT4 level in GD patients receiving methimazole (MMI) and 1α-D3 supplementation than those who only receive MMI alone [20]. The present study wants to identify whether the greater reduction of the fT4 level is also accompanied by immunological process, particularly inhibition of DC maturation on molecular aspects.

The results of our study demonstrate that oral supplementation of 1α-D3 for 8 weeks has not yet inhibited DC maturation, which is
Our study is the first RCT evaluating the effect of oral vitamin D on DC maturation in autoimmune disease. The first study is a study observing the effect of oral vitamin D supplementation on MR expression in autoimmune disease. A systematic review in 2012 about vitamin D supplementation in autoimmune diseases shows that out of 270 analyzed studies, there are only two RCTs; while others are observational study. Both RCTs reported the effect of 0.5 mcg oral 1α-D3 supplementation on lower needs of insulin and improved function of beta cells in patients with DM1 [25]. There is one RCT in 2013, which has not been incorporated into the systematic review. It discussed the effect of oral vitamin D on improved disease activity, inflammatory cytokines, and hemostatic profile of patients with SLE [15]. The previous three RCTs involving a greater number of autoimmune patients did not evaluate the profile of immune cells.

Our study is the second study which evaluates the effect of oral vitamin D on immune cells profile (DC maturation) in GD. It is also the first study observing the effect of oral vitamin D supplementation on MR expression in autoimmune disease. A systematic review in 2012 about vitamin D supplementation in autoimmune diseases shows that out of 270 analyzed studies, there are only two RCTs; while others are observational study. Both RCTs reported the effect of 0.5 mcg oral 1α-D3 supplementation on lower needs of insulin and improved function of beta cells in patients with DM1 [25]. There is one RCT in 2013, which has not been incorporated into the systematic review. It discussed the effect of oral vitamin D on improved disease activity, inflammatory cytokines, and hemostatic profile of patients with SLE [15]. The previous three RCTs involving a greater number of autoimmune patients did not evaluate the profile of immune cells.

Study limitation
For a clinical study, the in vivo design of our study has some limitation regarding the number of patients and a relatively short period of supplementation (8 weeks) compared to the previous clinical study (24 weeks) [20]. The small number of patients with heterogeneous patient profiles caused difficulty to observe and to obtain changes in the immune response during the short period observation.

Fig. 3: The level of fT4 before and after 8-week supplementation of 1α-D3 compared to placebo

characterized by insignificant lower expression of CD80 costimulatory molecule and persistent expression of MR (CD206). Although the results have not been significant yet, oral supplementation of 1α-D3 tends to demonstrate inhibition of DC maturation, which is characterized by lower expression of costimulatory molecule and the persistence of MR expression, while placebo supplementation tends to have higher expression of costimulatory molecule and lower MR expression. Lower costimulatory molecule expression and the persistence of MR molecules suggest that there is inhibition of DC maturation. There were no significant differences between oral 1α-D3 supplementation and placebo treatment on other DC markers, i.e., CD83, CD40, and CD14.

Effects of in vivo 1α-D3 on ratio of cytokines IL-12/IL-10 level in MDDC cultures of GD patients
Our study is the first study that evaluates the effect of oral vitamin D supplementation on the ratio of inflammatory (IL-12) and anti-inflammatory (IL-10) cytokine level in supernatant of MDDC culture of patients with autoimmune disease. Changes in IL-12/IL-10 ratio are strongly affected by IL-12 cytokine. Our study has not been able to show the effect of oral vitamin D supplementation on the ratio of IL-12/IL-10 levels in patients with GD since the ratio of IL-12/IL-10 levels among two groups was not significant.

Thyroid hormone (fT4) affects DC maturation; therefore, it correlates with IL-12 cytokines produced by DC [7]. The IL-12 cytokine level is high in GD patients who are still hyperthyroid and decreases with ATT treatment. This IL-12 decrement is correlated with decreased fT4 level (r=0.5) [27]. In our study, we did not find any correlation between fT4 and IL-12 cytokine level (r=0.06). The absence of correlation between fT4 and IL-12 cytokine level in our study might be due to the relatively short monitoring period (8 weeks) compared to other studies. A short monitoring period caused IL-12 level was not optimally reduced; therefore, our study did not find any significant correlation between fT4 and IL-12 levels. A study that shows correlation between fT4 and IL-12 cytokine levels had 12 months of monitoring period, and it demonstrates continuous reduction of IL-12 level until the 5th month of treatment although the fT4 level has reached the normal limit on the 2nd month of treatment [27].

Another clinical study associated with the role of vitamin D from sun exposure on changes of cytokines of GD patients was conducted in Jakarta with 32 GD patients, who were categorized into 2 groups, i.e., the exposure and non-exposure groups [28]. Results of the study showed that sun exposure three times a week for 20-30 minutes of each exposure for four weeks increased vitamin D level as much as 20% and inhibited the increment of IL-4 cytokine levels. IL-4 cytokine is a major stimulant for DC for IL-12 secretion; therefore, it is assumed that lower IL-4 cytokine will reduce IL-12 cytokine and it may lead to reducing activation of T cells. The study of sun exposure describes the important role of cytokines in GD [29].

Effect of oral 1α-D3 on fT4 level in GD patients
A study by Kawakami-Tani et al. [20] demonstrates that 1α-D3 supplementation decreases thyroid hormone (fT4, fT3) faster in hyperthyroid phase and increases TSH level faster in achieving euthyroid phase. After euthyroid, there is no difference of fT3 and fT4 levels between the 1α-D3 and placebo groups. In our study, both the mean of fT4 level after supplementation and percentage of fT4 level reduction were not different between both groups. There was an interesting phenomenon on the fT4 changes, i.e., in the placebo group there were two patients who experienced increased fT4 level during the study; while there was no patients in the treatment group who experienced increased fT4 level. It can be a good reason for conducting further studies on vitamin D supplementation in GD.

The response of fT4 level decrement in the first 8 weeks of our study was not as fast as the response found in Kawakami-Tani et al. study. In the Kawakami-Tani et al. study, on the 8th week, the fT4 level reached normal level in both groups and the TSH level began to elevate; while in our study, 8 out of 12 GD patients in the treatment group and 6 out of 13 GD patients in the placebo group still had fT4 level above normal limit and TSH levels had not increased among all patients. The difference in results between our study and Kawakami-Tani et al. study might be influenced by the ATT used; our study used PTU while Kawakami-Tani et al. study used MMI. The transition of hyperthyroid phase to euthyroid phase in our study has not been completed yet; therefore, immunological changes, particularly for DC maturation still cannot be demonstrated.
In addition to those factors, the baseline vitamin D level found in the patients also affects the outcomes. The effect of vitamin D supplementation will be more noticeable in patients with low baseline vitamin D level ( deficiency and insufficiency). In patients with vitamin D level that close to normal range, as found in our study, we need a longer observation period since the response to vitamin D supplementation tends to occur in sloping trends.

CONCLUSION

The effects of oral 1α-D3 supplementation for 8 weeks on DC maturation of GD patients have not been clearly demonstrated in this study yet.
