Abstract

We consider linear instability of solitary waves of several classes of dispersive long wave models. They include generalizations of KDV, BBM, regularized Boussinesq equations, with general dispersive operators and nonlinear terms. We obtain criteria for the existence of exponentially growing solutions to the linearized problem. The novelty is that we deal with models with nonlocal dispersive terms, for which the spectra problem is out of reach by the Evans function technique. For the proof, we reduce the linearized problem to study a family of nonlocal operators, which are closely related to properties of solitary waves. A continuation argument with a moving kernel formula are used to find the instability criteria. Recently, these techniques have also been extended to study instability of periodic waves and to the full water wave problem.

1 Introduction

We consider the stability and instability of solitary wave solutions of several classes of equations modeling weakly nonlinear, dispersive long waves. More specifically, we establish criteria for the linear exponential instability of solitary waves of BBM, KDV, and regularized Boussinesq type equations. These equations respectively have the forms:

1. BBM type

\[ \partial_t u + \partial_x u + \partial_x f(u) + \partial_t \mathcal{M} u = 0; \]  

(1.1)

2. KDV type

\[ \partial_t u + \partial_x f(u) - \partial_x \mathcal{M} u = 0; \]  

(1.2)

3. Regularized Boussinesq (RBou) type

\[ \partial_t^2 u - \partial_x^2 u - \partial_x^2 f(u) + \partial_t^2 \mathcal{M} u = 0. \]  

(1.3)

Here, the pseudo-differential operator \( \mathcal{M} \) is defined as

\[ (\mathcal{M}g)(k) = \alpha(k) \hat{g}(k), \]  

(1.4)
where \( \hat{g} \) is the Fourier transformation of \( g \). Throughout this paper, we assume: i) \( f \) is \( C^1 \) with \( f(0) = f'(0) = 0 \), and \( f(u)/u \to \infty \). ii) \( a |k|^m \leq \alpha(k) \leq b |k|^m \) for large \( k \), where \( m \geq 1 \) and \( a, b > 0 \). If \( f(u) = u^2 \) and \( M = -\partial_x^2 \), the above equations recover the original BBM ([11]), KDV ([28]), and regularized Boussinesq ([51]) equations, which have been used to model the unidirectional propagation of water waves of long wavelengths and small amplitude. As explained in [11], the nonlinear term \( f(u) \) is related to nonlinear effects suffered by the waves being modeled, while the form of the symbol \( \alpha(k) \) is related to dispersive and possibly, dissipative effects. If \( \alpha(k) \) is a polynomial function of \( k \), then \( M \) is a differential operator and in particular is a local operator. On the other hand, in many situations in fluid dynamics and mathematical physics, equations of the above type arise in which \( \alpha(k) \) is not a polynomial and hence the operator \( M \) is nonlocal. Some examples include: Benjamin-Ono equation ([12]), Smith equation ([47]) and intermediate long-wave equation ([29]), which are all of KDV type with \( \alpha(k) = |k|, \sqrt{1 + k^2} - 1 \) and \( k \coth(kH) - H^{-1} \) respectively.

Below we assume \( \alpha(k) \geq 0 \), since the results and proofs can be easily modified for cases of sign-changing symbols (see Section 5(b)). Each of the equations (1.1)-(1.3) admits solitary-wave solutions of the form

\[
 u_c(x) = 3c \sech^2 \left( \sqrt{cx}/2 \right)
\]

and for the Benjamin-Ono equation ([12])

\[
 u_c(x) = \frac{4c}{1 + ec^2x^2}.
\]

For a broad class of symbols \( \alpha \), the existence of solitary-wave solutions has been established ([9], [10]). For many equations such as the classical KDV and BBM, the solitary waves are positive, symmetric and single-humped. But the oscillatory solitary waves are not uncommon ([7], [6]), especially for the sign changing \( \alpha(k) \). In our study, we do not assume any additional property of solitary waves, besides their decay at infinity. We consider the linearized equations around solitary waves in the traveling frame \((x - ct, t)\) and seek a growing mode solution of the form \( e^{\lambda t} u(x) \) with \( \Re \lambda > 0 \). Define the operator \( \mathcal{L}_0 \) by (2.2), (4.4), and (3.5), and the momentum function \( P(c) \) by (2.23), (4.8), and (3.6), for BBM, KDV and RBou type equations respectively.

**Theorem 1** For solitary waves \( u_c(x - ct) \) of equations (1.1)-(1.3), we assume

\[
 \ker \mathcal{L}_0 = \{ u_{c_x} \}.
\]

Denote by \( n^- (\mathcal{L}_0) \) the number (counting multiplicity) of negative eigenvalues of the operators \( \mathcal{L}_0 \). Then there exists a purely growing mode \( e^{\lambda t} u(x) \) with \( \Re \lambda > 0 \), \( u \in H^m(\mathbb{R}) \) to the linearized equations (2.2), (4.2) and (3.2), if one of the following two conditions is true:

(i) \( n^- (\mathcal{L}_0) \) is even and \( dP/dc > 0 \).

(ii) \( n^- (\mathcal{L}_0) \) is odd and \( dP/dc < 0 \).
Note that the operators $\mathcal{L}_0$ are obtained from the linearization of equations satisfied by solitary waves, and $P(c) = Q(u_c)$ where $Q(u)$ is the momentum invariant due to the translation symmetry of the evolution equations (1.1)-(1.3). For example, for KDV type equations, $Q(u) = \frac{1}{2} \int u^2 \, dx$. The assumption (1.4) can be proved for $\mathcal{M} = -\partial_x^2$ and for some nonlocal dispersive operators ($\mathcal{P}$, $\mathcal{Q}$). It has the implication that the solitary wave branch $u_c(x)$ is unique. More discussions about the spectrum assumptions for $\mathcal{L}_0$ can be found in Section 5(a).

Let us relate our results to the literature on stability and instability of solitary waves. The first rigorous proof of stability of solitary waves is obtained by Benjamin (8), for the original KDV equation. Benjamin’s idea is to show that stable solitary waves are local energy minimizers under the constraint of constant momentum. This idea was already anticipated by Boussinesq (17) and has been extended to get stability results for more general settings (4, 3, 22, 50). In particular, it is shown in (14, 48) that for KDV and BBM type equations, the solitary waves are orbitally stable in the energy norm if and only if $dP/dc > 0$, under the hypothesis

$$\text{ker} \, \mathcal{L}_0 = \{u_{cx}\} \quad \text{and} \quad n^- (\mathcal{L}_0) = 1.$$  (1.5)

For power like nonlinear terms and dispersive operators with symbols $\alpha(k) = |k|^\alpha$, the function $P(c)$ can be computed by scaling and thus the more explicit stability criteria is obtained (see (14, 48)). The stability criterion $dP/dc > 0$ in (14, 48) is by a straight application of the abstract theory of (22), and this is also proved in (50). The instability proof of (22) can not apply directly to KDV and BBM cases. In (14, 48), the proof of (22) is modified to yield the instability criterion $dP/dc < 0$, by estimating the sublinear growth of the anti-derivative of the solution. A less technical way of modification (introduced in (31)) is described in Appendix for general settings.

Applying Theorem 1 to the KDV and BBM cases with $n^- (\mathcal{L}_0) = 1$, we recover the instability criterion $dP/dc < 0$ in (14, 48), and furthermore it helps to clarify the mechanism of this instability by finding a non-oscillatory and exponentially growing solution to the linearized problem. We note that the nonlinear instability proved in (14, 48) is in the energy norm $H^{m/2}$ and there is no estimate of the time scale for the growth of instability. The linear instability result might be the first step toward proving a stronger nonlinear instability result in $L^2$ norm with the exponential growth.

When $\mathcal{M} = -\partial_x^2$, Pego and Weinstein (43) study the spectral problem for solitary waves of BBM, KDV and RBou equations by the Evans function technique (1, 21), and a purely growing mode is shown to exist if $dP/dc < 0$. Since for $\mathcal{M} = -\partial_x^2$, we have $\text{ker} \, \mathcal{L}_0 = \{u_{cx}\}$ and $n^- (\mathcal{L}_0) = 1$ (see Section 5(a)), the result of (43) is a special case of Theorem 1. The novelty of our result is to allow general dispersive operators $\mathcal{M}$, particularly the nonlocal operators, for which the spectral problem can not be studied via the Evans functions. Comparison with the Evans functions are discussed more in Section 5(c). Moreover, our instability criteria for cases when $n^- (\mathcal{L}_0) \geq 2$ appear to be new, even for the relatively well-studied BBM and KDV type equations. The situation $n^- (\mathcal{L}_0) \geq 2$ might arise for highly oscillatory solitary waves (i.e. [7, 6]). Even for single-humped and positive solitary waves, it is not necessarily true that $n^- (\mathcal{L}_0) = 1$ since there is no Sturm theory for general operators $\mathcal{M}$. One such example is the large solitary waves for the full water wave problem. In (37), a simi-
lar instability criterion is derived for solitary waves, in terms of an operator \( \mathcal{L}_0 \) with 
\[ \alpha(k) = k \coth(kH), \]
for which \( n^- (\mathcal{L}_0) \) grows without bound as the solitary wave approaches the highest wave.

Let us discuss some implications of our results for solitary wave stability. The solitary waves of regularized Boussinesq equations are known ([46], [43]) to be highly indefinite (constrainted) energy saddles, and therefore their stability cannot be pursued by showing energy minimizers as in the BBM and KDV cases. More interestingly, solitary waves of the full water wave are also indefinite (constrainted) energy saddles ([13], [27]) and thus the study of stability of RBou solitary waves might shed some light on the full water wave problem. We note that energy saddles are not necessarily unstable. Indeed, it is shown in [45] that small solitary waves of the regularized Boussinesq equation are spectrally stable, that is, there are no growing modes to the linearized equation. So far, we do not know any method to prove nonlinear stability for energy saddle type solutions. The spectral stability is naturally the first step. The next theorem might be useful in the study of the spectral stability, in particular, for large solitary waves of RBou type equations.

**Theorem 2** Consider solitary waves \( u_c (x - ct) \) of equations (1.1)-(1.3), and assume 
\[ \ker \mathcal{L}_0 = \{u_{cx}\}. \]
Suppose all possible growing modes are purely growing and the spectral stability exchanges at \( c_0 \), then 
\[ P'(c_0) = 0. \]

For the original regularized Boussinesq equation, it is shown in [43, p. 79] that 
\[ P'(c) > 0 \] for any \( c^2 > 1 \). By Theorem 2 and the spectral stability of small solitary waves [45], it follows that either all solitary waves are spectrally stable or there is oscillatory instability for some solitary waves. So the spectral stability of large solitary waves would follow if one could exclude the oscillatory instability, namely, show that any growing mode must be purely growing. For BBM and KDV type equations, when 
\[ n^- (\mathcal{L}_0) \geq 2, \]
the solitary waves are also of energy saddle type and their stability could not studied by the usual energy argument. Above remarks also apply to these cases. We note that for KDV and BBM equations, under the hypothesis (1.5) the oscillatory instability can be excluded as in the case \( \mathcal{M} = -\partial_x^2 \) ([43, p. 79]), by adapting the finite-dimensional argument of [41].

We briefly discuss the proof of Theorem 1. The growing modes equations (2.4), (3.3) and (4.3) are non-self-adjoint eigenvalue problems for variable coefficient operators and rather few systematic techniques are available to study such problems. Our key step is to reformulate the spectral problems in terms of a family of operators \( \mathcal{A}^\lambda \), which has the form of \( \mathcal{M} \) plus some nonlocal but bounded terms. The idea is to try to relate the eigenvalue problems to the elliptic type problems for solitary waves. The existence of a purely growing mode is equivalent to find some \( \lambda > 0 \) such that \( \mathcal{A}^\lambda \) has a nontrivial kernel. This is achieved by a continuation strategy to exploit the difference of the spectra of \( \mathcal{A}^\lambda \) near infinity and zero. First, we show that the essential spectrum of \( \mathcal{A}^\lambda \) lies to the right and away from the imaginary axis. For large \( \lambda \), the spectra of the operator \( \mathcal{A}^\lambda \) is shown to lie entirely in the right half complex plane. So if for small \( \lambda \), the operator \( \mathcal{A}^\lambda \) has an odd number of eigenvalues in the left half plane, then the spectrum of \( \mathcal{A}^\lambda \) must get across the origin at some \( \lambda > 0 \) where a purely growing mode appears. The zero-limit operator \( \mathcal{A}^0 \) is exactly the operator \( \mathcal{L}_0 \). Since the
convergence of $A^\lambda$ to $L_0$ is rather weak, the usual perturbation theory does not apply and the asymptotic perturbation theory by Vock and Hunziker ([49]) is used to study perturbations of the eigenvalues of $L_0$. In particular, it is important to know how the zero eigenvalue of $L_0$ is perturbed, for which we derive a moving kernel formula. The instability criteria and Theorem [about the transition points follows from this formula. One important technical issue in the proof is to use the decay of solitary waves to obtain a priori estimates and gain certain compactness.

The approach of using nonlocal dispersion operators $A^\lambda$ with continuation to find instability criteria originates from our previous works ([34], [33], [32]) on 2D ideal fluid and 1D electrostatic plasma, which have also been extended to study instability of galaxies ([24]) and 3D electromagnetic plasmas ([35], [36]). The consideration of the movement of $\ker A^0$ is suggested in [33, Remark 3.2]. The techniques developed in this paper have been extended to get stability criteria for periodic dispersive waves ([39]), and to prove instability of large solitary and periodic waves for the full water wave problem ([37], [38]). This general approach might also be useful for to study instability in dispersive wave systems and multi-dimensional problems, which have been poorly understood.

This paper is organized as follows. In Section 2, we give details of the proof of Theorem [for the BBM case. Section 3 treats the R Bou case, whose proof is rather similar to the BBM case. The KDV case has some subtle difference to the previous cases and is discussed in Section 4. In Section 5, we discuss some extensions and open issues. The Appendix gives an alternative way of modifying the nonlinear instability proof in [22] to general dispersive long wave models.

2 The BBM type equations

Consider a traveling solution $u(x, t) = u_c(x - ct)$ ($c > 1$) of the BBM type equation (1.1). Then $u_c$ satisfies the equation

$$Mu_c + \left( 1 - \frac{1}{c} \right) u_c - \frac{1}{c} f'(u_c) = 0. \quad (2.1)$$

We define the following operator $L_0 : H^m \to L^2$ by the linearization of (2.1)

$$L_0 = M + \left( 1 - \frac{1}{c} \right) - \frac{1}{c} f'(u_c). \quad (2.2)$$

The linearized equation in the traveling frame $(x - ct, t)$ is

$$(\partial_t - c \partial_x) (u + Mu) + \partial_x (u + f'(u_c) u) = 0. \quad (2.3)$$

For a growing mode solution $e^{\lambda t} u(x)$ ($\Re \lambda > 0$) of (2.3), $u(x)$ satisfies

$$(\lambda - c \partial_x) (u + Mu) + \partial_x (u + f'(u_c) u) = 0, \quad (2.4)$$

which can be written as

$$Mu + u + \frac{\partial_x}{\lambda - c \partial_x} (u + f'(u_c) u) = 0.$$
This motivates us to define a family of operators $A^\lambda : H^m \to L^2$ by

$$A^\lambda u = Mu + u + \frac{\partial_x}{\lambda - c\partial_x} (u + f'(u_c)u).$$

Thus the existence of a growing mode is reduced to find $\lambda \in \mathbb{C}$ with $\text{Re} \, \lambda > 0$ such that the operator $A^\lambda$ has a nontrivial kernel. Below, we seek a purely growing mode with $\lambda > 0$. We use a continuation strategy, by exploiting the difference of the spectra of the operators $A^\lambda$ for $\lambda$ near infinity and zero. We divide the proof into several steps.

2.1 The properties of $A^\lambda$

Define the following operators

$$D = c\partial_x, \quad \mathcal{E}^{\lambda, \pm} = \frac{\lambda}{\lambda \pm D}.$$

Then the operator $A^\lambda (\lambda > 0)$ can be written as

$$A^\lambda = M + 1 - \frac{1}{c} \left( (1 - \mathcal{E}^{\lambda, -}) \left( 1 + f'(u_c) \right) \right).$$

Lemma 2.1 (a) For $\lambda > 0$, the operators $\mathcal{E}^{\lambda, \pm}$ are continuous in $\lambda$ and

$$\left\| \mathcal{E}^{\lambda, \pm} \right\|_{L^2 \to L^2} \leq 1, \quad \text{and} \quad \left\| 1 - \mathcal{E}^{\lambda, \pm} \right\|_{L^2 \to L^2} \leq 1.$$  \hfill \text{(2.5)}

(b) When $\lambda \to 0^+$, $\mathcal{E}^{\lambda, \pm}$ converges to 0 strongly in $L^2 (\mathbb{R})$.

(c) When $\lambda \to +\infty$, $\mathcal{E}^{\lambda, \pm}$ converges to 1 strongly in $L^2 (\mathbb{R})$.

Proof. We have

$$\left\| \mathcal{E}^{\lambda, \pm} \phi \right\|^2_{L^2} = \int_{\mathbb{R}} \left\| \frac{\lambda}{\lambda \pm i c k} \right\|^2 \left\| \hat{\phi} (k) \right\|^2 \, dk \leq \int_{\mathbb{R}} \left\| \hat{\phi} (k) \right\|^2 \, dk = \left\| \phi \right\|^2_{L^2}$$

and (2.5) follows. Similarly, we get the estimate (2.6). By the dominant convergence theorem,

$$\left\| \mathcal{E}^{\lambda, \pm} \phi \right\|^2_{L^2} = \int_{\mathbb{R}} \left\| \frac{\lambda}{\lambda \pm i c k} \right\|^2 \left\| \hat{\phi} (k) \right\|^2 \, dk \to 0,$$

when $\lambda \to 0^+$. Thus $\mathcal{E}^{\lambda, \pm} \to 0$ strongly in $L^2$. The proof of (c) is similar to that of (b) and we skip it. \hfill \blacksquare

Corollary 1 For $\lambda > 0$, the operator $A^\lambda$ converges to $\mathcal{L}_0$ strongly in $L^2$ when $\lambda \to 0^+$, and converges to $M + 1$ strongly in $L^2$ when $\lambda \to +\infty$.

The following theorem states that the essential spectrum of $A^\lambda$ is to the right and away from the imaginary axis.
Proposition 1 For any \( \lambda > 0 \), we have
\[
\sigma_{\text{ess}}(A^\lambda) \subset \left\{ z \mid \Re \lambda \geq \frac{1}{2} \left( 1 - \frac{1}{c} \right) > 0 \right\}.
\] (2.7)

The proof of Proposition 1 is based on the following lemmas.

Lemma 2.2 Consider any sequence
\[
\{u_n\} \in H^m(\mathbb{R}), \|u_n\|_2 = 1, \text{ supp } u_n \subset \{x \mid |x| \geq n\}.
\]
Then for any complex number \( z \) with \( \Re z < \frac{1}{2} \left( 1 - \frac{1}{c} \right) \), we have
\[
\Re ((A^\lambda - z) u_n, u_n) \geq \frac{1}{4} \left( 1 - \frac{1}{c} \right),
\]
when \( n \) is large enough.

Proof. We have
\[
\Re ((A^\lambda - z) u_n, u_n)
= ((M + 1) u_n, u_n) - \Re z - \Re \left( \frac{1}{c} \left( 1 - \mathcal{E}^{\lambda -} \right) \left( 1 + f'(u_c) \right) u_n, u_n \right)
= ((M + 1) u_n, u_n) - \Re z - \frac{1}{c} \Re \left( \left( 1 + f'(u_c) \right) u_n, \left( 1 - \mathcal{E}^{\lambda +} \right) u_n \right)
\geq 1 - \frac{1}{2} \left( 1 - \frac{1}{c} \right) - \frac{1}{c} \left( 1 + \max_{|x| \geq n} |f'(u_c)| \right) \| \left( 1 - \mathcal{E}^{\lambda +} \right) u_n \|_2
\geq \frac{1}{2} \left( 1 - \frac{1}{c} \right) - \frac{1}{c} \max_{|x| \geq n} |f'(u_c)| \quad \text{(by Lemma 2.1(a))}
\geq 1 - \frac{1}{4} \left( 1 - \frac{1}{c} \right), \quad \text{when } n \text{ is big enough.}
\]

To study the essential spectrum of \( A^\lambda \), first we introduce the Zhislin Spectrum \( Z(A^\lambda) \) (25). A Zhislin sequence for \( A^\lambda \) and \( z \in \mathbb{C} \) is a sequence
\[
\{u_n\} \in H^m(\mathbb{R}), \|u_n\|_2 = 1, \text{ supp } u_n \subset \{x \mid |x| \geq n\}
\]
and \( \| (A^\lambda - z) u_n \|_2 \to 0 \) as \( n \to \infty \). The set of all \( z \) such that a Zhislin sequence exists for \( A^\lambda \) and \( z \) is denoted \( Z(A^\lambda) \). From the above definition and Lemma 2.2 we readily have
\[
Z(A^\lambda) \subset \left\{ z \in \mathbb{C} \mid \Re z \geq \frac{1}{2} \left( 1 - \frac{1}{c} \right) \right\}.
\] (2.8)

Another related spectrum is the Weyl spectrum \( W(A^\lambda) \) (25). A Weyl sequence for \( A^\lambda \) and \( z \in \mathbb{C} \) is a sequence \( \{u_n\} \in H^m, \|u_n\|_2 = 1, u_n \to 0 \) weakly in \( L^2 \) and \( \| (A^\lambda - z) u_n \|_2 \to 0 \) as \( n \to \infty \). The set \( W(A^\lambda) \) is all \( z \in \mathbb{C} \) such that a Weyl
sequence exists for \(A^\lambda\) and \(z\). By ([25, Theorem 10.10]), \(W(A^\lambda) \subset \sigma_{\text{ess}}(A^\lambda)\) and the boundary of \(\sigma_{\text{ess}}(A^\lambda)\) is contained in \(W(A^\lambda)\). So it suffices to show that \(W(A^\lambda) = Z(A^\lambda)\), which together with (2.3) implies (2.7). By ([25, Theorem 10.12]), the proof of \(W(A^\lambda) = Z(A^\lambda)\) is reduced to prove the following lemma.

**Lemma 2.3** Given \(\lambda > 0\). Let \(\chi \in C_0^\infty(R)\) be a cut-off function such that \(\chi|_{\{|x| \leq R_0\}} = 1\), for some \(R_0 > 0\). Define \(\chi_d = \chi(x/d), d > 0\). Then for each \(d\), \(\chi_d (A^\lambda - z)^{-1}\) is compact for some \(z \in \rho(A^\lambda)\), and that there exists \(C(d) \to 0\) as \(d \to \infty\) such that for any \(u \in C_0^\infty(R)\),

\[
\| [A^\lambda, \chi_d]\|_{L^2 	o L^2} \leq C(d) (\|A^\lambda u\|_2 + \|u\|_2). \tag{2.9}
\]

**Proof.** We write \(A^\lambda = M + 1 + K^\lambda\), where

\[
K^\lambda = \frac{1}{c} \left(1 - E^{\lambda,-}\right) (1 + f'(u_c)) : L^2 \to L^2 \tag{2.10}
\]

is bounded. So \(-k \in \rho(A^\lambda)\) when \(k > 0\) is sufficiently large. The compactness of \(\chi_d (A^\lambda + k)^{-1}\) is a corollary of the local compactness of \(H^m \hookrightarrow L^2\). To show (2.9), we note that the graph norm of \(A^\lambda\) is equivalent to \(\|\cdot\|_{H^m}\). Below, we use \(C\) to denote a generic constant. First, we have

\[
[k^\lambda, \chi_d] = -\frac{1}{c} [E^{\lambda,-}, \chi_d] (1 + f'(u_c)) = -\frac{1}{c} \frac{1}{\lambda - D} [D, \chi_d] \frac{1}{\lambda - D} (1 + f'(u_c))
\]

\[
= \frac{1}{\lambda c d} E^{\lambda,-} (x/d) E^{\lambda,-} (1 + f'(u_c))
\]

and thus

\[
\| [k^\lambda, \chi_d]\|_{L^2 \to L^2} \leq \frac{C}{\lambda d}. \tag{2.11}
\]

Let \(l = \lfloor m \rfloor\) to be the largest integer no greater than \(m\) and \(\delta = m - \lfloor m \rfloor \in [0, 1)\). Define the following two operators

\[
M_1 = \left\{ \begin{array}{ll}
1 + \left(\frac{d}{d^l}\right)^l & \text{if } l \not\equiv 0 \mod 4 \\
1 - \left(\frac{d}{d^l}\right)^l & \text{if } l \equiv 0 \mod 4.
\end{array} \right. \tag{2.12}
\]

and \(M_2\) is the Fourier multiplier operator with the symbol

\[
n(k) = \left\{ \begin{array}{ll}
\frac{\alpha(k)}{1 + i \delta(k)} & \text{if } l \not\equiv 0 \mod 4 \\
\frac{\alpha(k)}{1 - i \delta(k)} & \text{if } l \equiv 0 \mod 4.
\end{array} \right. \tag{2.13}
\]

Then \(M = M_2 M_1\) and

\[
[M, \chi_d] = M_2 [M_1, \chi_d] + [M_2, \chi_d] M_1.
\]
We study \([M_2, \chi_d]\) in two cases. When \(\delta = 0\), that is, \(m\) is an integer, for any \(v \in C_0^\infty (\mathbb{R})\), we follow [19, P.127-128] to write
\[
[M_2, \chi_d] v = -(2\pi)^{-\frac{1}{2}} \int \tilde{n}(x - y) (\chi_d (x) - \chi_d (y)) v(y) \, dy
\]
\[
= - \int_0^1 \int (2\pi)^{-\frac{1}{2}} (x - y) \tilde{n}(x - y) \chi_d' (\rho (x - y) + y) v(y) \, dy \, d\rho
\]
\[
= \int_0^1 A_\rho v \, d\rho,
\]
where \(A_\rho\) is the integral operator with the kernel function
\[
K_\rho (x, y) = -(2\pi)^{-\frac{1}{2}} (x - y) \tilde{n}(x - y) \chi_d' (\rho (x - y) + y).
\]
Note that \(\beta (x) = x \tilde{n}(x)\) is the inverse Fourier transformation of \(in' (k)\) and \(n' (k)\) \(\in L^2\) when \(l = m\), so \(\beta (x) \in L^2\). Thus
\[
\int \int |K_\rho (x, y)|^2 \, dx \, dy = 2\pi \int \int |\beta|^2 (x - y) |\chi'_d|^2 (\rho (x - y) + y) \, dx \, dy
\]
\[
= 2\pi \int \int |\beta|^2 (x) |\chi'_d|^2 (y) \, dx \, dy = 2\pi \|\beta\|_{L^2} \|\chi'_d\|_{L^2}^2
\]
\[
= \frac{2\pi}{d} \|\beta\|_{L^2} \|\chi'_d\|_{L^2}^2.
\]
So
\[
\| [M_2, \chi_d] \|_{L^2 \rightarrow L^2} \leq \frac{C}{d^2}
\]
and
\[
\| [M_2, \chi_d] M_1 u \|_{L^2} \leq \frac{C}{d^2} \| M_1 u \|_{L^2} \leq \frac{C}{d^2} \| u \|_{H^m}.
\]
When \(\delta > 0\), we define two Fourier multiplier operators \(M_3\) and \(M_4\) with symbols \(1 + |k|^{\delta}\) and \(n_1 (k) = n (k) / (1 + |k|^{\delta})\) respectively. Then \(M_2 = M_3 M_4\) and
\[
[M_2, \chi_d] = M_4 [M_3, \chi_d] + [M_4, \chi_d] M_3.
\]
Since \(n_1' (k) \in L^2\), by the same argument as above, we have
\[
\| [M_4, \chi_d] \|_{L^2 \rightarrow L^2} \leq \frac{C}{d^2}.
\]
By [42, P. 213, Theorem 3.3],
\[
\| [M_3, \chi_d] \|_{L^2 \rightarrow L^2} \leq C (\delta) \| D^{\delta} \chi_d \|_s,
\]
where \(|D|^{\delta}\) is the fractional differentiation operator with the symbol \(|k|^{\delta}\) and \(\| \cdot \|_s\) is the BMO norm. By using Fourier transformations, it is easy to check that
\[
\left( |D|^{\delta} \chi_d \right) (x) = \frac{1}{d^\delta} \left( |D|^{\delta} \chi \right) \left( \frac{x}{d} \right).
\]
A has a nontrivial kernel. We use a continuation strategy, by comparing the behavior of Lemma 2.4

\[ \{ \]

and therefore

\[ \| [M_3, \chi_d] \|_{L^2 \to L^2} \leq \frac{C}{d^\delta}. \]

Since \( \| M_4 \|_{L^2 \to L^2} \) is bounded, we have

\[ \| [M_2, \chi_d] M_1 u \|_{L^2} \leq \| M_4 [M_3, \chi_d] M_1 u \|_{L^2} + \| [M_4, \chi_d] M_3 M_1 u \|_{L^2} \]

\[ \leq \frac{C}{d^\delta} \| M_1 u \|_{L^2} + \frac{C}{d^\frac{\delta}{2}} \| M_3 M_1 u \|_{L^2} \leq C \left( \frac{1}{d^\delta} + \frac{1}{d^\frac{\delta}{2}} \right) \| u \|_{H^m}. \]

So in both cases,

\[ \| [M_2, \chi_d] M_1 u \|_{L^2} \leq C (d) \| u \|_{H^m}, \text{ with } C (d) \to 0 \text{ as } d \to \infty. \quad (2.14) \]

Since

\[ [M_1, \chi_d] = \sum_{j=1}^l C_j \frac{d^j \chi_d}{dx^j} \frac{d^{l-j}}{dx^{l-j}} \text{ or } - \sum_{j=1}^l C_j \frac{d^j \chi_d}{dx^j} \frac{d^{l-j}}{dx^{l-j}}, \]

and

\[ \frac{d^j \chi_d}{dx^j} (x) = \frac{1}{d^j} \chi^{(j)} \left( \frac{x}{d} \right) := \frac{1}{d^j} \chi_d^{(j)}, \]

we have

\[ \| M_2 [M_1, \chi_d] u \|_{L^2} \leq \sum_{j=1}^l \frac{C}{d^\delta} \left( \| [M_2, \chi_d^{(j)}] u^{(l-j)} \|_{L^2} + \| \chi \| C_l \| M_2 u^{(l-j)} \|_{L^2} \right). \]

By similar estimates as above, when \( \delta = 0, \)

\[ \| [M_2, \chi_d^{(j)}] u^{(l-j)} \|_{L^2} \leq \frac{C}{d^\frac{\delta}{2}} \| u^{(l-j)} \|_{L^2} \leq \frac{C}{d^\frac{\delta}{2}} \| u \|_{H^m} \]

and when \( \delta > 0, \)

\[ \| [M_2, \chi_d^{(j)}] u^{(l-j)} \|_{L^2} \leq \frac{C}{d^\delta} \| u^{(l-j)} \|_{L^2} + \frac{C}{d^\frac{\delta}{2}} \| M_3 u^{(l-j)} \|_{L^2} \leq C \left( \frac{1}{d^\delta} + \frac{1}{d^\frac{\delta}{2}} \right) \| u \|_{H^m}. \]

Thus

\[ \| M_2 [M_1, \chi_d] u \|_{L^2} \leq C (d) \| u \|_{H^m}, \text{ with } C (d) \to 0 \text{ as } d \to \infty. \]

Combining above with (2.11) and (2.14), we get the estimate (2.9). This finishes the proof of the lemma and Proposition 1.

To show the existence of growing modes, we need to find some \( \lambda > 0 \) such that \( A^\lambda \) has a nontrivial kernel. We use a continuation strategy, by comparing the behavior of \( A^\lambda \) near 0 and infinity. First, we study the case near infinity.

Lemma 2.4 There exists \( \Lambda > 0, \) such that when \( \lambda > \Lambda, \) \( A^\lambda \) has no eigenvalues in \( \{ z \mid \text{Re } z \leq 0 \}. \)
Proof. Suppose otherwise, then there exists a sequence \( \{\lambda_n\} \to \infty \), and \( \{k_n\} \in \mathbb{C}, \{u_n\} \in H^m(\mathbb{R}) \), such that \( \text{Re} \, k_n \leq 0 \) and \( (\mathcal{A}^{\lambda_n} - k_n) \, u_n = 0 \). Since \( \|\mathcal{A}^{\lambda} - \mathcal{M} - 1\| = ||\mathcal{K}^\lambda|| \leq M \) for some constant \( M \) independent of \( \lambda \) and \( \mathcal{M} \) is a self-adjoint positive operator, all discrete eigenvalues of \( \mathcal{A}^{\lambda} \) lie in

\[
D_M = \{z \mid \text{Re} \, z \geq -M \text{ and } |\text{Im} \, z| \leq M\}.
\]

Therefore, \( k_n \to k_\infty \in D_M \) with \( \text{Re} \, k_\infty \leq 0 \). Denote \( e(x) = (f'(u_c))^2 \), then \( e(x) \to 0 \) when \( |x| \to \infty \). We normalize \( u_n \) by setting \( \|u_n\|_{L^2} = 1 \), where

\[
\|u\|_{L^2} = \left( \int e(x) |u|^2 \, dx \right)^{\frac{1}{2}}.
\]

We claim that

\[
\|u_n\|_{H^\infty} = C, \text{ for a constant } C \text{ independent of } n.
\]  (2.16)

Assuming (2.16), we have \( u_n \to u_\infty \) weakly in \( H^m \). Moreover, \( u_\infty \neq 0 \). To show that, we choose \( R > 0 \) large enough such that \( \max_{|x| \geq R} e(x) \leq \frac{1}{2C} \). Then

\[
\int_{|x| \geq R} e(x) |u_n|^2 \, dx \leq \frac{1}{2C} \|u_n\|_{L^2} \leq \frac{1}{2}
\]

Since \( u_n \to u_\infty \) strongly in \( L^2(\{|x| \leq R\}) \), we have

\[
\int_{|x| \leq R} e(x) |u_\infty|^2 \, dx = \lim_{n \to \infty} \int_{|x| \leq R} e(x) |u_n|^2 \, dx \geq \frac{1}{2}
\]

and thus \( u_\infty \neq 0 \). By Corollary II, \( \mathcal{A}^{\lambda_n} \to \mathcal{M} + 1 \) strongly in \( L^2 \), therefore \( \mathcal{A}^{\lambda_n} \, u_n \to (\mathcal{M} + 1) \, u_\infty \) weakly and \( (\mathcal{M} + 1) \, u_\infty = k_\infty \, u_\infty \). Since \( \text{Re} \, k_\infty \leq 0 \), this a contradiction. It remains to show (2.16). From \( \mathcal{A}^{\lambda_n} - k_n \, u_n = 0 \), we get

\[
0 \geq \text{Re} \, k_n \|u_n\|_2^2 = ((\mathcal{M} + 1) \, u_n, u_n) - \frac{1}{C} \text{Re} \left( (1 - \mathcal{E}^{\lambda_n}) \, u_n \right)
\]

By our assumption on the symbol \( \alpha(k) \) of \( \mathcal{M} \), there exists \( K > 0 \) such that \( \alpha(k) \geq a \frac{|k|^m}{|k|^m} \) when \( |k| \geq K \). So for any \( \epsilon, \delta > 0 \), from above and Lemma 2.1, we have

\[
0 \geq \left( 1 - \delta \right) \|u_n\|_{L^2}^2 + \frac{1}{C} \left| \int_{|k| \geq K} |k|^m \, |\hat{u}(k)|^2 \, dk + \frac{1}{C} \int_{|k| \leq K} |\hat{u}(k)|^2 \, dk \right.
\]

\[
- \frac{1}{C} \|u_n\|_{L^2}^2 - \frac{1}{C} \|u_n\|_{L^2} \|u_n\|_{L^2}
\]

\[
\geq \left( 1 - \delta \right) \|u_n\|_{L^2}^2 + \min \left\{ \frac{\delta}{K^m}, a \right\} \left( \int_{|k| \geq K} |k|^m \, |\hat{u}(k)|^2 \, dk - \frac{1}{C} \|u_n\|_{L^2}^2 \right.
\]

\[
- \epsilon \|u_n\|_{L^2}^2 - \frac{\epsilon}{4C^2} \|u_n\|_{L^2}^2 - \frac{\epsilon}{4C^2} \|u_n\|_{L^2}^2
\]

\[
\geq \min \left\{ 1 - \frac{1}{C} - \delta - \epsilon, \frac{\delta}{K^m}, a \right\} \|u_n\|_{H^\infty}^2 - \frac{\epsilon}{4C^2} \|u_n\|_{L^2}^2
\]

The bound (2.16) follows by choosing \( \delta, \epsilon > 0 \) small. \( \blacksquare \)
2.2 Asymptotic perturbations near \( \lambda = 0 \)

In this subsection, we study the spectra of \( A^\lambda \) for small \( \lambda \). When \( \lambda \to 0^+ \), \( A^\lambda \to L_0 \) strongly in \( L^2 \), where \( L_0 \) is defined by (2.2). Since the convergence of \( A^\lambda \to L_0 \) is rather weak, we could not use the regular perturbation theory. Instead, we use the asymptotic perturbation theory developed by Vock and Hunziker ([49]), see also [25], [26]. To apply this theory, we need some preliminary lemmas.

**Lemma 2.5** Given \( F \in C_0^\infty (\mathbb{R}) \). Consider any sequence \( \lambda_n \to 0^+ \) and \( \{u_n\} \in H^m (\mathbb{R}) \) satisfying

\[
\|A^{\lambda_n} u_n\|_2 + \|u_n\|_2 \leq M_1 < \infty
\]

for some constant \( M_1 \). Then if \( w - \lim_{n \to \infty} u_n = 0 \), we have

\[
\lim_{n \to \infty} \|F u_n\|_2 = 0
\]

and

\[
\lim_{n \to \infty} \| [A^{\lambda_n}, F] u_n \|_2 = 0.
\]

**Proof.** Since (2.17) implies that \( \|u_n\|_{H^m} \leq C \), (2.18) follows from the local compactness of \( H^m \hookrightarrow L^2 \). To prove (2.19), we use the notations in the proof of Lemma 2.3. We write \( A^{\lambda_n} = M + 1 + K^{\lambda_n} \). Note that

\[
[M, F] = [M_2 M_1, F] = M_2 [M_1, F] + [M_2, F] M_1,
\]

where \( M_1 \) and \( M_2 \) are defined in (2.12) and (2.13). Let \( G \in C_0^\infty (\mathbb{R}) \) satisfying \( G = 1 \) on the support of \( F \). For any \( \varepsilon > 0 \), we have

\[
\|[M_1, F] u_n\|_2 = \|[M_1, F] G u_n\|_2 = \left\| \sum_{j=1}^{l} C_j \frac{d^j F}{dx^j} \frac{d^{l-j} (G u_n)}{dx^{l-j}} \right\|_2
\]

\[
\leq C \|u_n\|_{H^{l-1}} \leq \varepsilon \|u_n\|_{H^m} + C \varepsilon \|G u_n\|_2.
\]

Since \( \varepsilon \) is arbitrarily small and the second term tends to zero by the local compactness, it follows that \( \| [M_1, F] u_n \|_2 \to 0 \) when \( n \to \infty \). Since \( n' (k) \to 0 \) when \( |k| \to \infty \), by [19] Theorem C the commutator \( [M_2, F] : L^2 \to L^2 \) is compact. Since \( \|M_1 u_n\|_2 \leq \|u_n\|_{H^m} \leq C \) and \( u_n \to 0 \) weakly in \( L^2 \), we have \( M_1 u_n \to 0 \) weakly in \( L^2 \). So

\[
\|[M_2, F] M_1 u_n\|_2 \to 0
\]

strongly in \( L^2 \) and thus \( \|[M, F] u_n\|_2 \to 0 \). Since

\[
[M^{\lambda_n}, F] u_n = -\frac{1}{c} [\mathcal{E}^{\lambda_n -}, F] (1 + f' (u_c)) u_n
\]

\[
= -\frac{1}{c} \mathcal{E}^{\lambda_n} F (1 + f' (u_c)) u_n + \frac{1}{c} F \mathcal{E}^{\lambda_n} (1 + f' (u_c)) u_n = p_n + q_n.
\]

Denote \( v_n = (1 + f' (u_c)) u_n \). From the uniform bound of \( \|v_n\|_{H^m} \), we get the uniform bound for \( \|v_n\|_{H^m} \). Therefore, by local compactness,

\[
\|p_n\|_2 \leq C \|F v_n\|_2 \to 0, \text{ when } n \to \infty.
\]
Since the operator $\|E^{\lambda,-}\|_{L^2 \to L^2} \leq 1$ and $E^{\lambda,-}$ is commutable with $\left(1 - \frac{\partial^2}{\partial x^2}\right)^{\frac{m}{2}}$, for any $\lambda > 0$, we have the estimate

$$\|E^{\lambda,-}\|_{H^m \to H^m} \leq 1.$$  

So denoting $\tilde{v}_n = E^{\lambda,n,-}v_n$, we have the uniform bound for $\|\tilde{v}_n\|_{H^m}$ and thus

$$\|p_n\|_2 \leq C \|F\tilde{v}_n\|_2 \to 0,$$

when $n \to \infty$. This finishes the proof of (2.19). □

**Lemma 2.6** Let $z \in \mathbb{C}$ with $\text{Re } z \leq \frac{1}{2} \left(1 - \frac{1}{c}\right)$, then for some $n > 0$ and all $u \in C^\infty_0 (|x| \geq n)$, we have

$$\|(A^\lambda - z) u\|_2 \geq \frac{1}{4} \left(1 - \frac{1}{c}\right) \|u\|_2,$$  

(2.20)

when $\lambda$ is sufficiently small.

**Proof.** The estimate (2.20) follows from

$$\text{Re } ((A^\lambda - z) u, u) \geq \frac{1}{4} \left(1 - \frac{1}{c}\right) \|u\|_2^2,$$  

(2.21)

which can be obtained as in the proof of Lemma 2.2. □

With above two lemmas, we can apply the asymptotic perturbation theory ([25], [49]) to get the eigenvalue perturbations of $A^0$ to $A^\lambda$ with small $\lambda$.

**Proposition 2** Each discrete eigenvalue $k_0$ of $A^0$ with $k_0 \leq \frac{1}{2} \left(1 - \frac{1}{c}\right)$ is stable with respect to the family $A^\lambda$ in the following sense: there exists $\lambda_1, \delta > 0$, such that for $0 < \lambda < \lambda_1$, we have

(i) $B (k_0; \delta) = \{z | 0 < |z - k_0| < \delta\} \subset P (A^\lambda),$

where

$$P (A^\lambda) = \left\{z | R^\lambda (z) = (A^\lambda - z)^{-1} \text{ exists and is uniformly bounded for } \lambda \in (0, \lambda_1)\right\}.$$  

(ii) Denote

$$P_\lambda = \oint_{\{|z-k_0|=\delta\}} R^\lambda (z) \, dz \quad \text{and} \quad P_0 = \oint_{\{|z-k_0|=\delta\}} R^0 (z) \, dz$$

to be the perturbed and unperturbed spectral projection. Then $\dim P_\lambda = \dim P_0$ and $\lim_{\lambda \to 0} \|P_\lambda - P_0\| = 0$.

It follows from above that for $\lambda$ small, the operators $A^\lambda$ have discrete eigenvalues inside $B (k_0; \delta)$ with the total algebraic multiplicity equal to that of $k_0$.  

13
To understand the entire spectrum of $A^\lambda$ for small $\lambda$, we need to know precisely how the zero eigenvalue of $A^0 = L^0$ is perturbed. For that, we derive a moving kernel formula, from which the instability criterion follows. Let $\lambda_1, \delta > 0$ be as in Proposition 2 for $k_0 = 0$. By our assumption that $\ker A^0 = \{u_{cx}\}$, so $\dim P_0 = 1$ and thus $\dim P_\lambda = 1$ for $\lambda < \lambda_1$. Since the eigenvalues of $A^\lambda$ appear in conjugate pairs, there is only one real eigenvalue $k_\lambda$ of $A^\lambda$ inside $B(0; \delta)$. The following lemma determines the sign of $k_\lambda$, when $\lambda$ is sufficiently small.

**Lemma 2.7** Assume $\ker L^0 = \{u_{cx}\}$. For $\lambda > 0$ small enough, let $k_\lambda \in \mathbb{R}$ to be the only eigenvalue of $A^\lambda$ near origin. Then

$$\lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda^2} = -\frac{1}{c} \frac{dP}{dc} \frac{\|u_{cx}\|_{L^2}^2}{\|u_{cx}\|_{L^2}^2},$$

(2.22)

where the momentum

$$P(c) = \frac{1}{2} (\mathcal{M}+1) u_c, u_c$$

(2.23)

By the same proof of (2.16), we get the following a priori estimate which is used in the later proof.

**Lemma 2.8** For $\lambda > 0$ small enough, consider $u \in H^m(\mathbb{R})$ satisfying the equation $(A^\lambda - z) u = v$, where $z \in \mathbb{C}$ with $\text{Re} z \leq \frac{1}{2} (1 - \frac{1}{c})$ and $v \in L^2$. Then we have the estimate

$$\|u\|_{H^m} \leq C \left( \|u\|_{L^2} + \|v\|_{L^2} \right),$$

(2.24)

for some constant $C$ independent of $\lambda$. Here, the weighted norm $\|\cdot\|_{L^2}$ is defined in (2.15).

Assuming Lemma 2.7, we prove Theorem 1 for BBM type equations.

**Proof of Theorem 4.3 (BBM).** We prove (ii) and the proof of (i) is similar. Assume that $n^{-}(L_0)$ is odd and $dP/dc < 0$. Let $k_1^-, \cdots , k_l^-$ be all the distinct negative eigenvalues of $L_0$. Choose $\delta > 0$ small such that the $l$ disks $B(k_i^-; \delta)$ are disjoint and still lie in the left half plane. By Proposition 2, there exists $\lambda_1 > 0$ and $\delta$ small enough, such that for $0 < \lambda < \lambda_1$, $A^\lambda$ has $n^{-}(L_0)$ eigenvalues (counting multiplicity) in $\bigcup_{i=1}^l B(k_i^-; \delta)$. By Lemma 2.7 if $dP/dc < 0$, then the zero eigenvalue of $A^0$ is perturbed to a positive eigenvalue $0 < k_\lambda < \delta$ of $A^\lambda$ for small $\lambda$. Consider the region

$$\Omega = \{ z \mid 0 > \text{Re} z > -2M \text{ and } |\text{Im} z| < 2M \},$$

where $M$ is the uniform bound for $\|K^\lambda\| = \|A^\lambda - \mathcal{M} - 1\|$. We claim that: for $\lambda$ small enough, $A^\lambda$ has exactly $n^{-}(L_0) + 1$ eigenvalues (with multiplicity) in

$$\Omega_\delta = \{ z \mid 2\delta > \text{Re} z > -2M \text{ and } |\text{Im} z| < 2M \}.$$
That is, all eigenvalues of $A^\lambda$ with real parts no greater than $2\delta$ lie in $\cup_{i=1}^l B(k_i^-; \delta) \cup B(0; \delta)$. Suppose otherwise, there exists a sequence $\lambda_n \to 0$ and $$\{u_n\} \subset H^m(\mathbf{R}), \quad z_n \in \Omega/(\cup_{i=1}^l B(k_i^-; \delta) \cup B(0; \delta))$$ such that $(A^{\lambda_n} - z_n)u_n = 0$. We normalize $u_n$ by setting $\|u_n\|_{L^2} = 1$. Then by Lemma 2.8 we have $\|u_n\|_{H^\frac{m}{2}} \leq C$. By the same argument as in the proof of Lemma 2.4 $u_n \to u_\infty \neq 0$ weakly in $H^\frac{m}{2}$. Let $$\lim_{n \to \infty} z_n = z_\infty \in \bar{\Omega}/(\cup_{i=1}^l B(k_i^-; \delta) \cup B(0; \delta))$$ then $\mathcal{L}^0u_\infty = z_\infty u_\infty$, which is a contradiction. The claim is proved and thus for $\lambda$ small enough, $A^\lambda$ has exactly $n^-$ ($\mathcal{L}_0$) eigenvalues in $\Omega$.

Suppose Theorem 4.3 (i) is not true, then $A^\lambda$ has no kernel for any $\lambda > 0$. Define $n_\Omega(\lambda)$ to be the number of eigenvalues (with multiplicity) of $A^\lambda$ in $\Omega$. Since by Lemma 2.7 the region $\Omega$ is away from the essential spectrum of $A^\lambda$, $n_\Omega(\lambda)$ is always a finite integer. In the above, we have proved that $n_\Omega(\lambda) = n^-(\mathcal{L}_0)$ is odd, for $\lambda$ small enough. By Lemma 2.4 there exists $\Lambda > 0$ such that $n_\Omega(\lambda) = 0$ for $\lambda > \Lambda$. Define two sets $$S_{\text{odd}} = \{\lambda > 0 | n_\Omega(\lambda) = \text{odd}\}, \quad S_{\text{even}} = \{\lambda > 0 | n_\Omega(\lambda) = \text{even}\}.$$ Then both sets are non-empty. Below, we show that both $S_{\text{odd}}$ and $S_{\text{even}}$ are open sets.

Let $\lambda_0 \in S_{\text{odd}}$ and denote $k_1, \ldots, k_l$ ($1 \leq \lambda \leq l$) to be all distinct eigenvalues of $A^{\lambda_0}$ in $\Omega$. Denote $ih_1, \ldots, ih_p$ to be all eigenvalues of $A^{\lambda_0}$ on the imaginary axis. Then $|h_j| \leq M, 1 \leq j \leq p$. Choose $\delta > 0$ sufficiently small such that the disks $B(k_i; \delta)$ ($1 \leq i \leq l$) and $B(ih_j; \delta)$ ($1 \leq j \leq p$) are disjoint, $B(k_i; \delta) \subset \Omega$ and $B(ih_j; \delta)$ does not contain $0$. Note that $A^\lambda$ is analytic in $\lambda$ for $\lambda \in (0, +\infty)$. By the analytic perturbation theory (2.5), if $|\lambda - \lambda_0|$ is sufficiently small, any eigenvalue of $A^\lambda$ in $\Omega_\delta$ lies in one of the disks $B(k_i; \delta)$ or $B(ih_j; \delta)$. So $n_\Omega(\lambda)$ is the number $n_\Omega(\lambda_0) + \text{the number of eigenvalues in } \cup_{i=1}^l B(k_i; \delta) \cup B(ih_j; \delta)$ with the negative real part. The second number is even, since the complex eigenvalues of $A^\lambda$ appears in conjugate pairs. Thus, $n_\Omega(\lambda)$ is odd for $|\lambda - \lambda_0|$ small enough. This shows that $S_{\text{odd}}$ is open. Similarly, $S_{\text{even}}$ is open. Thus, $(0, +\infty)$ is the union of two non-empty, disjoint open sets $S_{\text{odd}}$ and $S_{\text{even}}$. This is a contradiction.

So there exists $\lambda > 0$ and $0 \neq u \in H^m(\mathbf{R})$ such that $A^\lambda u = 0$. Then $e^{\lambda t}u(x)$ is purely growing mode solution to (2.3). One could also get more regularity of $u(x)$, as in the usual proof of the regularity of solitary waves (i.e. (10)).

It remains to prove the moving kernel formula (2.22).

**Proof of Lemma 2.7** We use $C$ to denote a generic constant in our estimates below. As described at the beginning of this subsection, for $\lambda > 0$ small enough, there exists $u_\lambda \in H^m(\mathbf{R})$, such that $(A^\lambda - k_\lambda) u_\lambda = 0$ with $k_\lambda \in \mathbf{R}$ and $\lim_{\lambda \to 0^+} k_\lambda = 0$. We normalize $u_\lambda$ by setting $\|u_\lambda\|_{L^2} = 1$. Then by Lemma 2.8 we have $\|u_\lambda\|_{H^\frac{m}{2}} \leq C$ and as in the proof of Lemma 2.4 $u_\lambda \to u_0 \neq 0$ weakly in $H^\frac{m}{2}$. Since $A^0 u_0 = \mathcal{L}_0 u_0 = 0$ and $\ker \mathcal{L}_0 = \{u_{\text{cx}}\}$, we have $u_0 = c_\text{0} u_{\text{cx}}$ for some $c_0 \neq 0$. Moreover, we have $\|u_\lambda - u_0\|_{H^\frac{m}{2}} = 0$. To show that, first we note that $\|u_\lambda - u_0\|_{L^2} \to 0$, since $$\|u_\lambda - u_0\|_{L^2}^2 \leq \int_{|x| \leq R} e(x)|u_\lambda - u_0|^2 \, dx + \max_{|x| \geq R} e(x) \|u_\lambda - u_0\|_{L^2}^2,$$
we have
\[ \| u_\lambda - u_0 \|_{H^1} \leq C \left( \| u_\lambda - u_0 \|_{L^2}^2 + |k_\lambda| \| u_0 \|_{L^2}^2 + \| (A^0 - A^\lambda) u_0 \|_{L^2}^2 \right) \to 0, \]
when \( \lambda \to 0^+ \). We can assume \( c_0 = 1 \) by renormalizing the sequence.

Next, we show that \( \lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda} u_\lambda = 0 \). From \( (A^\lambda - k_\lambda) u_\lambda = 0 \), we have
\[ \frac{k_\lambda}{\lambda} u_\lambda = A^0 \frac{u_\lambda}{\lambda} + A^\lambda - A^0 \frac{u_\lambda}{\lambda}. \quad (2.25) \]
Taking the inner product of above with \( u_{cx} \), we get
\[ \frac{k_\lambda}{\lambda} (u_\lambda, u_{cx}) = \left( \frac{A^\lambda - A^0}{\lambda} u_\lambda, u_{cx} \right) := m(\lambda). \]
We have
\[
m(\lambda) = \left( \frac{1}{c} \frac{1}{\lambda - D} (1 + f'(u_c)) u_\lambda, u_{cx} \right) = \frac{1}{c} \left( (1 + f'(u_c)) u_\lambda, \frac{1}{\lambda + D} u_{cx} \right)
\]
\[= \frac{1}{c^2} \left( (1 + f'(u_c)) u_\lambda, (1 - D^{\lambda, +}) u_{cx} \right) \to \frac{1}{c^2} \left( (1 + f'(u_c)) u_{cx}, u_{cx} \right)
\]
\[= \frac{1}{c^2} \int f'(u_c) sds \left( \frac{1}{2} u_{cx}^2 + F(u_c) \right) dx = 0,
\]
where \( F(u) = \int_0^u f'(s) ds \) and in the above \( \lim_{\lambda \to 0^+} D^{\lambda, +} = 0 \) is used. So
\[
\lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda} = \lim_{\lambda \to 0^+} \frac{m(\lambda)}{u_\lambda, u_{cx}} = 0.
\]
We write \( u_\lambda = c_\lambda u_{cx} + \lambda v_\lambda \), where \( c_\lambda = (u_\lambda, u_{cx}) / (u_{cx}, u_{cx}) \). Then \( (v_\lambda, u_{cx}) = 0 \) and \( c_\lambda \to 1 \) when \( \lambda \to 0^+ \). We claim that: \( \| v_\lambda \|_{L^2} \leq C \) (independent of \( \lambda \)). Suppose otherwise, there exists a sequence \( \lambda_n \to 0^+ \) such that \( \| v_{\lambda_n} \|_{L^2} \geq n \). Denote \( \tilde{v}_{\lambda_n} = v_{\lambda_n} / \| v_{\lambda_n} \|_{L^2} \). Then \( \| \tilde{v}_{\lambda_n} \|_{L^2} = 1 \) and \( \tilde{v}_{\lambda_n} \) satisfies the equation
\[ A^{\lambda_n} \tilde{v}_{\lambda_n} = \frac{1}{\| \tilde{v}_{\lambda_n} \|_{L^2}} \left( k_{\lambda_n} \frac{u_{\lambda_n}}{\lambda_n} - c_{\lambda_n} \frac{A^{\lambda_n} - A^0}{\lambda_n} u_{cx} \right). \quad (2.26) \]
Denote
\[ w_\lambda(x) = \frac{A^\lambda - A^0}{\lambda} u_{cx}, \]
then
\[
\frac{w_\lambda(x) = \frac{1}{c} \frac{1}{\lambda - D} (1 + f'(u_c)) u_{cx} = \frac{1}{\lambda - D} d \left( (M + 1) u_c \right)
\]
\[= \frac{1}{c} \frac{D}{\lambda - D} (M + 1) u_c = \frac{1}{c} (D^{\lambda, -} - 1) (M + 1) u_c,
\]
and the second term is arbitrarily small for large \( R \) while the first term tends to zero by the local compactness. Since
\[ (A^\lambda - k_\lambda) (u_\lambda - u_0) = k_\lambda u_0 + (A^0 - A^\lambda) u_0, \]
where we use the equation

$$\mathcal{L}_0 u_{ex} = \mathcal{M} u_{ex} + \left(1 - \frac{1}{c}\right) u_{ex} - \frac{1}{c} f'(u_c) u_{ex} = 0.$$ 

By Lemma 2.1, \(\|w_\lambda\|_{L^2} \leq C\) (independent of \(\lambda\)), and

$$w_\lambda(x) \rightarrow -\frac{1}{c}(\mathcal{M} + 1) u_c = \frac{1}{c^2} (u_c + f(u_c))$$

(2.27)

strongly in \(L^2\), when \(\lambda \rightarrow 0^+\). So by Lemma 2.8, we have \(\|v_{\lambda_n}\|_H^{\frac{n}{2}} \leq C\). Then, as before, \(\bar{v}_{\lambda_n} \rightarrow \bar{v}_0 \neq 0\) weakly in \(H^{\frac{n}{2}}\). Since \(\frac{k_{\lambda_n}}{\lambda_n} \rightarrow 0\), we have \(A^0 \bar{v}_0 = 0\).

So \(\bar{v}_0 = c_1 u_{ex}\) for some \(c_1 \neq 0\). But since \((\bar{v}_{\lambda_n}, u_{ex}) = 0\), we have \((\bar{v}_0, u_{ex}) = 0\), a contradiction. This establishes the uniform bound for \(v_\lambda\) weakly in \(H^{\frac{n}{2}}\). By (2.27), \(v_\lambda\) tends to

$$A^0 v_\lambda = \mathcal{L}_0 v_\lambda = \frac{1}{c} (\mathcal{M} + 1) u_c.$$ 

Taking \(\partial_c\) of (2.1), we have

$$(\mathcal{L}_0 \partial_c u_c) = -\frac{1}{c} (\mathcal{M} + 1) u_c.$$ 

(2.28)

Thus \(\mathcal{L}_0 (v_0 + \partial_c u_c) = 0\). Since \((v_0, u_{ex}) = \lim_{\lambda \rightarrow 0^+} (v_\lambda, u_{ex}) = 0\), we have

$$v_0 = -\partial_c u_c + d_0 u_{ex}, \quad d_0 = (\partial_c u_c, u_{ex}) / \|u_{ex}\|_{L^2}^2.$$ 

Similar to the proof of \(\|u_\lambda - u_0\|_H^{\frac{n}{2}} \rightarrow 0\), we have \(\|v_\lambda - v_0\|_H^{\frac{n}{2}} \rightarrow 0\). We rewrite

$$u_\lambda = c_\lambda u_{ex} + \lambda v_\lambda = \tilde{c}_\lambda u_{ex} + \lambda \tilde{v}_\lambda,$$

where \(\tilde{c}_\lambda = c_\lambda + \lambda d_0\), \(\tilde{v}_\lambda = v_\lambda - d_0 u_{ex}\). Then \(\tilde{c}_\lambda \rightarrow 1\), \(\tilde{v}_\lambda \rightarrow -\partial_c u_c\) when \(\lambda \rightarrow 0^+\).

Now we compute \(\lim_{\lambda \rightarrow 0^+} \frac{A^0 u_\lambda}{\lambda^2}\). From (2.25), we have

$$A^0 \frac{u_\lambda}{\lambda^2} + \frac{A^0 - A^0}{\lambda} \left(\frac{\tilde{c}_\lambda}{\lambda^2} u_{ex} + \tilde{v}_\lambda\right) = \frac{k_{\lambda}}{\lambda^2} u_\lambda.$$ 

Taking the inner product of above with \(u_{ex}\), we have

$$\frac{k_{\lambda}}{\lambda^2} (u_\lambda, u_{ex}) = \tilde{c}_\lambda \left(\frac{A^0 - A^0}{\lambda^2} u_{ex}, u_{ex}\right) + \left(\frac{A^0 - A^0}{\lambda} \tilde{v}_\lambda, u_{ex}\right) = \tilde{c}_\lambda I_1 + I_2.$$
For the first term, we have

\[ I_1 = \left( \frac{A^\lambda - A^0}{\lambda^2} u_{cx}, u_{cx} \right) = \left( \frac{w_\lambda(x)}{\lambda}, u_{cx} \right) = \frac{1}{c} \left( \frac{D}{(\lambda - D)} (\mathcal{M} + 1) u_c, u_{cx} \right) \]

\[ = \frac{1}{c} \left( \frac{1}{\lambda - D} (\mathcal{M} + 1) u_c, u_{cx} \right) - \frac{1}{c^2} \left( u_c + f(u_c), u_{cx} \right) \]

\[ = -\frac{1}{c^2} \left( (\mathcal{E}^\lambda - 1) (\mathcal{M} + 1) u_c, u_{cx} \right) + \frac{1}{c^2} \left( (\mathcal{M} + 1) u_c, u_{cx} \right) \]

\( \text{when } \lambda \to 0^+ . \)

For the second term, we have

\[ I_2 = \left( \frac{A^\lambda - A^0}{\lambda} \tilde{v}_\lambda, u_{cx} \right) = \frac{1}{c} \left( \frac{D}{\lambda - D} (1 + f'(u_c)) \tilde{v}_\lambda, u_{cx} \right) \]

\[ = -\frac{1}{c^2} \left( \frac{D}{\lambda - D} (1 + f'(u_c)) \tilde{v}_\lambda, u_{cx} \right) = -\frac{1}{c^2} \left( (\mathcal{E}^\lambda - 1) (1 + f'(u_c)) \tilde{v}_\lambda, u_{cx} \right) \]

\[ \to -\frac{1}{c^2} ((1 + f'(u_c)) \partial_c u_c, u_{cx}), \text{ when } \lambda \to 0. \]

Thus

\[ \lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda^2} = \lim_{\lambda \to 0^+} \tilde{v}_\lambda I_1 + I_2 \]

\[ = \left[ \frac{1}{c^2} ((\mathcal{M} + 1) u_c, u_{cx}) - \frac{1}{c^2} (1 + f'(u_c)) \partial_c u_c, u_{cx} \right] / \| u_{cx} \|_{L^2}^2 \]

\[ = -\frac{1}{c} ((\mathcal{M} + 1) \partial_c u_c, u_{cx}) = -\frac{1}{c} \frac{dP}{dc}, \]

since by (2.28)

\[ (\mathcal{M} + 1) u_c - (1 + f'(u_c)) \partial_c u_c = -c (\mathcal{M} + 1) \partial_c u_c. \]

\[ \blacksquare \]

3 Regularized Boussinesq type

Consider a solitary wave \( u(x,t) = u_c(x - ct) \) \((c^2 > 1)\) of the regularized Boussinesq (RBou) type equation \((1.3)\). Then \(u_c\) satisfies the equation

\[ \mathcal{M} u_c + \left( 1 - \frac{1}{c^2} \right) u_c - \frac{1}{c^2} f(u_c) = 0. \quad (3.1) \]

The linearized equation in the traveling frame \((x - ct, t)\) is

\[ (\partial_t - c\partial_x)^2 (u + \mathcal{M} u) - \partial_x^2 (u + f'(u_c) u) = 0. \quad (3.2) \]
For a growing mode $e^{\lambda t}u(x)$ ($\text{Re}\,\lambda > 0$), $u(x)$ satisfies
\[
(\lambda - c\partial_x)^2(u + Mu) - \partial_x^2(u + f'(u_c)u) = 0.
\] (3.3)
So we define the following dispersion operator $A^\lambda : H^m \to L^2(\lambda > 0)$
\[
A^\lambda u = Mu + u - \left(\frac{\partial_x}{\lambda - c\partial_x}\right)^2(u + f'(u_c)u)
\]
and the existence of a purely growing mode is reduced to find $\lambda > 0$ such that $A^\lambda$ has a nontrivial kernel. Since when $\lambda \to 0^+$,
\[
\frac{\partial_x}{\lambda - c\partial_x} = \frac{D}{\lambda - D} = \frac{1}{c} \left(\mathcal{E}_\lambda - 1\right) \to -\frac{1}{c} \text{ strongly in } L^2,
\] (3.4)
the zero limit of the operator $A^\lambda$ is
\[
\mathcal{L}_0 := M + \left(1 - \frac{1}{c^2}\right) - \frac{1}{c^2} f'(u_c).
\] (3.5)

The proof of Theorem for RBou case is very similar to the BBM case, so we only give a sketch of the proof of the moving kernel formula.

**Lemma 3.1** Assume $\ker\mathcal{L}_0 = \{u_{ex}\}$. For $\lambda > 0$ small enough, let $k_\lambda \in \mathbb{R}$ to be the only eigenvalue of $A^\lambda$ near zero. Then we have
\[
\lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda^2} = -\frac{1}{c^2} \frac{dP}{dc} / \|u_{ex}\|_{L^2}^2,
\]
where
\[
P(c) = c((M+1)u_c, u_c).
\] (3.6)

**Proof.** For $\lambda > 0$ small enough, let
\[
u_\lambda \in H^m(\mathbb{R}), \; k_\lambda \in \mathbb{R}, \; \lim_{\lambda \to 0^+} k_\lambda = 0,
\]
such that $(A^\lambda - k_\lambda)u_\lambda = 0$. We normalize $u_\lambda$ by setting $\|u_\lambda\|_{L^2} = 1$. Then as in the BBM case, we have $\|u_\lambda\|_{L^2} \leq C$ and $u_\lambda \to u_{ex}$ in $H^\infty$ by a renormalization, under our assumption that $\ker\mathcal{L}_0 = \{u_{ex}\}$.

First, we show that $\lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda} = 0$. As in the BBM case, we have
\[
\frac{k_\lambda}{\lambda} (u_\lambda, u_{ex}) = \left(\frac{A^\lambda - A^0}{\lambda}u_\lambda, u_{ex}\right) := m(\lambda),
\]
where
\[
\frac{A^\lambda - A^0}{\lambda} = \frac{1}{c^2} \left(\frac{2}{\lambda - D} - \frac{\lambda}{(\lambda - D)^2}\right) (1 + f'(u_c)).
\]
We have

\[ m(\lambda) = \frac{1}{c^2} \left( \frac{2}{\lambda - D} - \frac{\lambda}{(\lambda - D)^2} \right) (1 + f'(u_c)) u_{\lambda, u_{cx}} \]

\[ = \frac{1}{c^2} \left( 1 + f'(u_c) \right) u_{\lambda, \left( \frac{2}{\lambda + D} - \frac{\lambda}{(\lambda + D)^2} \right) u_{cx}} \]

\[ = \frac{1}{c^3} \left( 1 + f'(u_c) \right) u_{\lambda, \left( \frac{2D}{\lambda + D} - \frac{\lambda D}{(\lambda + D)^2} \right) u_c} \]

\[ = \frac{1}{c^3} \left( 1 + f'(u_c) \right) u_{\lambda, (1 - E^{\lambda,+}) (2 - E^{\lambda,+}) u_c} \]

\[ \rightarrow \frac{2}{c^3} \left( 1 + f'(u_c) \right) u_{cx, u_c} = 0, \]

and thus

\[ \lim_{\lambda \to 0^+} \frac{k_{\lambda}}{\lambda} = \lim_{\lambda \to 0^+} \frac{m(\lambda)}{u_{\lambda, u_{cx}}} = 0. \]

Similarly to the BBM case, we can show that \( u_{\lambda} = \bar{c}_{\lambda} u_{cx} + \lambda \bar{v}_{\lambda} \), with \( \bar{c}_{\lambda} \to 1 \), \( \bar{v}_{\lambda} \to -\partial_c u_c \) in \( H^{\frac{m}{2}} \), when \( \lambda \to 0^+ \). In the proof, we use the facts that

\[ w_{\lambda}(x) = \frac{A^\lambda - A^0}{\lambda} u_{cx} = \frac{1}{c^2} \left( \frac{2}{\lambda - D} - \frac{\lambda}{(\lambda - D)^2} \right) (1 + f'(u_c)) u_{cx} \]

\[ = \left( \frac{2}{\lambda - D} - \frac{\lambda}{(\lambda - D)^2} \right) (M + 1) u_{cx} = \frac{1}{c} \left( \frac{2D}{\lambda - D} - \frac{\lambda D}{(\lambda - D)^2} \right) (M + 1) u_c \]

\[ = \frac{1}{c} (E^{\lambda,-} - 1) (2 - E^{\lambda,-}) (M + 1) u_c \rightarrow -\frac{2}{c} (M + 1) u_c, \text{ when } \lambda \to 0^+. \]

and

\[ L_0 \partial_c u_c = -\frac{2}{c^3} (u_c + f(u_c)) = -\frac{2}{c} (M + 1) u_c. \quad (3.7) \]

Next, we compute \( \lim_{\lambda \to 0^+} \frac{k_{\lambda}}{\lambda^2} \) by using

\[ \frac{k_{\lambda}}{\lambda^2} (u_{\lambda}, u_{cx}) = \bar{c}_{\lambda} \left( \frac{A^\lambda - A^0}{\lambda^2} u_{cx, u_{cx}} + \left( \frac{A^\lambda - A^0}{\lambda} \bar{v}_{\lambda}, u_{cx} \right) = \bar{c}_{\lambda} I_1 + I_2. \]
For the first term, we have

\[ I_1 = \left( \frac{A^\lambda - A^0}{\lambda^2} u_{cex}, u_{cex} \right) = \left( \frac{u_{\lambda}(x)}{\lambda}, u_{cex} \right) \]

\[ = \frac{1}{c} \left( \left[ \frac{2D}{(\lambda - D) \lambda} - \frac{D}{(\lambda - D)^2} \right] (\mathcal{M} + 1) u_c, u_{cex} \right) \]

\[ = -\frac{1}{c^2} \left( \left[ \frac{2D^2}{(\lambda - D) \lambda} - \frac{D^2}{(\lambda - D)^2} \right] (\mathcal{M} + 1) u_c, u_{cex} \right) \]

\[ = -\frac{2}{c^2} \left( (\mathcal{E}^{\lambda, -} - 1) (\mathcal{M} + 1) u_c, u_{cex} \right) + \frac{1}{c^2 \lambda} (D (\mathcal{M} + 1) u_c, u_{cex}) \]

\[ + \frac{1}{c^2} \left( (\mathcal{E}^{\lambda, -} - 1)^2 (\mathcal{M} + 1) u_c, u_{cex} \right) \]

\[ \to -\frac{3}{c^2} ((\mathcal{M} + 1) u_c, u_{cex}), \text{ when } \lambda \to 0+, \]

since \( \mathcal{E}^{\lambda, -} \to 0 \) and

\[ (D (\mathcal{M} + 1) u_c, u_{cex}) = c (u_{cex}, (\mathcal{M} + 1) u_c) = \frac{1}{c} (u_{cex}, u_c + f (u_c)) = 0. \]

For the second term, we have

\[ I_2 = \left( \frac{A^\lambda - A^0}{\lambda} \tilde{v}_\lambda, u_{cex} \right) = \frac{1}{c^2} \left( \left[ \frac{2D}{\lambda - D} - \frac{\lambda}{(\lambda - D)^2} \right] (1 + f'(u_c)) \tilde{v}_\lambda, u_{cex} \right) \]

\[ = -\frac{1}{c^3} \left( \left[ \frac{2D^2}{(\lambda - D) \lambda} - \frac{\lambda D}{(\lambda - D)^2} \right] (1 + f'(u_c)) \tilde{v}_\lambda, u_{cex} \right) \]

\[ = -\frac{1}{c^3} \left( (\mathcal{E}^{\lambda, -} - 1) (2 - \mathcal{E}^{\lambda, -}) (1 + f'(u_c)) \tilde{v}_\lambda, u_{cex} \right) \]

\[ \to -\frac{2}{c^3} ((1 + f'(u_c)) \partial_c u_c, u_{cex}), \text{ when } \lambda \to 0+. \]

Thus

\[ \lim_{\lambda \to 0+} \frac{k_4^\lambda}{\lambda^2} = \lim_{\lambda \to 0+} \frac{\tilde{v}_\lambda I_1 + I_2}{(u_\lambda, u_{cex})} \]

\[ = \left[ \frac{3}{c^2} ((\mathcal{M} + 1) u_c, u_c) - \frac{2}{c^3} ((1 + f'(u_c)) \partial_c u_c, u_{cex}) \right] / \|u_{cex}\|_{L^2}^2 \]

\[ = \left[ \frac{-1}{c^2} ((\mathcal{M} + 1) u_c, u_c) - \frac{2}{c} ((\mathcal{M} + 1) \partial_c u_c, u_{cex}) \right] / \|u_{cex}\|_{L^2}^2 \]

\[ = -\frac{1}{c^2} \frac{dP}{dc} / \|u_{cex}\|_{L^2}^2, \]

since by (3.2)

\[ (1 + f'(u_c)) \partial_c u_c = c^2 (\mathcal{M} + 1) \partial_c u_c + 2c (\mathcal{M} + 1) u_c. \]
As a corollary of the above proof, we show Theorem 2 for the RBou case. We skip the proof of Theorem 2 for the BBM and KDV cases, since they are very similar. Theorem 2 (RBou) follows from the next lemma.

**Lemma 3.2** Assume $\ker L_0 = \{u_{cx}\}$. If there is a sequence of purely growing modes $e^{\lambda_n t}u_n(x) (\lambda_n > 0)$ for solitary waves $u_{cn}$ of (1.3), with $\lambda_n \to 0^+, c_n \to c_0$, then we must have $P'(c_0) = 0$.

**Proof.** The proof is almost the same as that of Lemma 3.1, so we only sketch it. The only difference is that now the computations depend on the parameter $c_n$. Denote $\mathcal{E}_{\pm} = \pm \frac{\lambda_n}{\lambda_n - c_n} \partial_x$, then by the same argument as in the proof of Lemma 2.1, we have $s - \lim_{n \to \infty} \mathcal{E}_{\pm} = 0$. Then the operator

$$\mathcal{A}^{\lambda_n, c_n} = \mathcal{M} + 1 - \left( \frac{\partial_x}{\lambda_n - c_n \partial_x} \right)^2 (1 + f'(u_{cn}))$$

converges to

$$\mathcal{L}_0 := \mathcal{M} + \left( 1 - \frac{1}{c_0^2} \right) - \frac{1}{c_0^2} f'(u_{cn})$$

strongly in $L^2$. We have $\mathcal{A}^{\lambda_n, c_n} u_n = 0$ and we normalize $u_n$ by $\|u_n\|_{L^2_{\infty}} = 1$, where $e_n = |f'(u_{cn})|^2$. As before, it can be shown that $\|u_n\|_{H^{\frac{m}{2}}} \leq C$ (independent of $n$) and $u_n \to u_{cn}$ in $H^{\frac{m}{2}}$. Moreover, we have $u_n = \bar{c}_n u_{cn,x} + \lambda_n \bar{v}_n$, where $\bar{c}_n \to 1$ and $\bar{v}_n \to -\partial_c u_{cn}|_{c_0}$ in $H^{\frac{m}{2}}$. From $\mathcal{A}^{\lambda_n, c_n} u_n = 0$, it follows that

$$0 = \bar{c}_n \left( \mathcal{A}^{\lambda_n, c_n} - \mathcal{A}^{0, c_n} \right) u_{cn,x} + \left( \mathcal{A}^{\lambda_n, c_n} - \mathcal{A}^{0, c_n} \right) \bar{v}_n, u_{cn,x} \right) = \bar{c}_n I_1 + I_2,$$

where

$$\mathcal{A}^{0, c_n} = \mathcal{M} + \left( 1 - \frac{1}{c_n^2} \right) - \frac{1}{c_n^2} f'(u_{cn}) \right).$$

By the same computations as in the proof of Lemma 3.1

$$I_1 = -\frac{2}{c_n^2} \left( (\mathcal{E}^2 - 1) (\mathcal{M} + 1) u_{cn}, u_{cn} \right) + \frac{1}{c_n^2} \left( (\mathcal{E}^2 - 1) (\mathcal{M} + 1) u_{cn}, u_{cn} \right)$$

$$\to -\frac{3}{c_0^2} \left( (\mathcal{M} + 1) u_{cn}, u_{cn} \right), \text{ when } n \to \infty$$

and

$$I_2 \to -\frac{2}{c_0^2} \left( (1 + f'(u_{cn})) \partial_c u_{cn}|_{c_0}, u_{cn} \right), \text{ when } n \to \infty.$$

Thus

$$0 = \lim_{n \to \infty} (\bar{c}_n I_1 + I_2) = \frac{1}{c_0^2} \frac{dP}{dc} (c_0)$$

and the Lemma is proved.
4 KDV type

Consider a solitary wave $u(x,t) = u_c(x - ct)$ ($c > 0$) of the KDV type equations \[1.2\]. Then $u_c$ satisfies the equation

$$Mu_c + cu_c - f(u_c) = 0.$$ \[4.1\]

The linearized equation is

$$\left(\partial_t - c\partial_x\right)u + \partial_x(f'(u_c)u - Mu) = 0.$$ \[4.2\]

and for a growing mode solution $e^{\lambda t}u(x)$ ($\Re\lambda > 0$), $u(x)$ satisfies

$$\left(\lambda - c\partial_x\right)u + \partial_x(f'(u_c)u - Mu) = 0.$$ \[4.3\]

We define the following dispersion operator $A^\lambda : H^m \to L^2 (\Re\lambda > 0)$

$$A^\lambda u = cu + \frac{c\partial_x}{\lambda - c\partial_x}(f'(u_c)u - Mu)$$

and as before the existence of a purely growing mode is reduced to find $\lambda > 0$ such that $A^\lambda$ has a nontrivial kernel. When $\lambda \to 0^+$, $A^\lambda$ converges to the zero-limit operator

$$L_0 := M + c - f'(u_c).$$ \[4.4\]

The proof of Theorem 1 for KDV is similar to the BBM and RBou cases. So we only indicate some differences due to the different structure of the operator $A^\lambda$. To prove the essential spectrum bound

$$\sigma_{\text{ess}}(A^\lambda) \subset \left\{ z \mid \Re\lambda \geq \frac{1}{2}c \right\},$$ \[4.5\]

we need to establish analogues of Lemmas 2.2 and 2.3. First, we note that, for any $u \in H^m (\mathbb{R})$,

$$\Re \left( -\frac{c\partial_x}{\lambda - c\partial_x}Mu, u \right) = \Re \int \frac{-ick}{\lambda - ick}a(k) \left| \hat{\phi}(k) \right|^2 dk$$ \[4.6\]

$$= \int \frac{(ck)^2}{\lambda^2 + (ck)^2}a(k) \left| \hat{\phi}(k) \right|^2 dk \geq 0.$$

So by estimates as in the proof of Lemma 2.2 for any sequence

$$\{u_n\} \in H^m (\mathbb{R}), \|u_n\|_2 = 1, \supp u_n \subset \{x \mid |x| \geq n\},$$

and any complex number $z$ with $\Re z \leq \frac{1}{2}c$, we have

$$\Re \left( (A^\lambda - z) u_n, u_n \right) \geq \frac{1}{4}c,$$

when $n$ is large enough. Since

$$[A^\lambda, \chi_d] = (1 - E^\lambda) \left[ M, \chi_d \right] + [E^\lambda, \chi_d] (f'(u_c) - M),$$

the conclusion of Lemma 2.3 still holds true by the same proof. Thus the essential spectrum bound \[4.5\] is obtained as before. The non-existence of growing modes for large $\lambda$ is proved in the following lemma.
Lemma 4.1 There exists $\Lambda > 0$, such that when $\lambda > \Lambda$, $A^\lambda$ has no eigenvalues in \{\(z\mid \text{Re} \, z \leq 0\)\}.

Proof. Suppose otherwise, then there exists a sequence \({\lambda_n}\} \to +\infty$, \({k_n}\} \in \mathbb{C}$, and \({u_n}\} \in H^m(\mathbb{R})$, such that $\text{Re} \, k_n \leq 0$ and $(A^{k_n} - k_n) u_n = 0$. Let $K > 0$ be such that $\alpha (k) \geq \alpha |k|^m$ when $|k| \geq K$. For any $\delta, \varepsilon > 0$, and large $n$, we have $\delta \lambda_n \geq K$ and

$$0 \geq \Re \left(A^{k_n} u_n, u_n\right)$$

$$\geq \int \frac{(ck)^2 \alpha (k)}{\lambda_n^2 + (ck)^2} |\hat{u}_n (k)|^2 \, dk + c \|u_n\|_{L^2}^2 \max |f' (u_c)| \|u_n\|_{L^2} \left|\frac{c \partial_x}{\lambda_n + c \partial_x} u_n\right|_{L^2}$$

$$\geq \int \frac{(ck)^2 \alpha (k)}{\lambda_n^2 + (ck)^2} |\hat{u}_n (k)|^2 \, dk + (c - \varepsilon) \|u_n\|_{L^2}^2 \max |f' (u_c)| \frac{2}{4\varepsilon} \int \frac{(ck)^2 \alpha (k)}{\lambda_n^2 + (ck)^2} |\hat{u}_n (k)|^2 \, dk$$

$$\geq \int \frac{(ck)^2 \alpha (k)}{\lambda_n^2 + (ck)^2} |\hat{u}_n (k)|^2 \, dk - \max \frac{|f' (u_c)|^2 c^2 \delta^2}{4\varepsilon} \int_{|k| \leq \delta \lambda_n} |\hat{u}_n (k)|^2 \, dk$$

$$\geq (1 - \max \frac{|f' (u_c)|^2 c^2 \delta^2}{4\varepsilon}) \int \frac{(ck)^2 \alpha (k)}{\lambda_n^2 + (ck)^2} |\hat{u}_n (k)|^2 \, dk + (c - \varepsilon - \max \frac{|f' (u_c)|^2 c^2 \delta^2}{4\varepsilon}) \|u_n\|_{L^2}^2$$

$$> 0,$$

by choosing $\varepsilon, \delta > 0$ such that

$$c - \varepsilon - \frac{\max |f' (u_c)| c^2 \delta^2}{4\varepsilon} > 0.$$

This is a contradiction and the lemma is proved. $\blacksquare$

The eigenvalues of $A^\lambda$ for small $\lambda$ are also studied by the asymptotic perturbation theory. The required analogues of Lemmas 2.5 and 2.6 can be proved in the same way. The discrete eigenvalues of $A^0 = \mathcal{L}_0$ are perturbed to get the eigenvalues of $A^\lambda$ for small $\lambda$, in the sense of Proposition 2. The instability criterion in Theorem 1 can be proved in the same way, by deriving the following moving kernel formula: for $\lambda > 0$ small enough, let $k_\lambda \in \mathbb{R}$ to be the only eigenvalue of $A^\lambda$ near zero, then

$$\lim_{\lambda \to 0} \frac{k_\lambda}{\lambda^2} = -\frac{dP}{dc} / \|u_c\|_{L^2}^2,$$

where

$$P (c) = \frac{1}{2} (u_c, u_c).$$

We sketch the proof of (4.7) below. First, similar to Lemma 2.8, we have the following a priori estimate:

For $\lambda > 0$ small enough, if $(A^\lambda - z) u = v$, $z \in \mathbb{C}$ with $\text{Re} \, z \leq \frac{1}{2} c$ and $v \in L^2$, then

$$\|u\|_{\dot{H}^\frac{1}{2}} \leq C \left(\|u\|_{L^2} + \|v\|_{L^2}\right),$$

$$\text{(4.9)}$$

24
for a constant $C$ independent of $\lambda$. To prove (4.9), we note that for any $\varepsilon > 0$
\[
\text{Re} \left( A^\lambda u, u \right) - \frac{1}{2} c \| u \|^2_{L^2} \leq \| u \|_{L^2} \| v \|_{L^2} \leq \varepsilon \| u \|^2_{L^2} + \frac{1}{4\varepsilon} \| v \|^2_{L^2}
\]
and for any $\delta > 0$, when $\lambda \leq cK$,
\[
\text{Re} \left( A^\lambda u, u \right) \geq \int \frac{(ck)^2}{\lambda^2 + (ck)^2} |\hat{u}(k)|^2 \, dk + c \| u \|^2_{L^2} - \| u \|_{L^2} \| u_\alpha \|_{L^2}
\]
\[
\geq \frac{a}{2} \int_{|k| \geq K} |k|^m |\hat{u}(k)|^2 \, dk + c \| u \|^2_{L^2} - \| u \|_{L^2}^2 - \frac{1}{4\varepsilon} \| u \|^2_{L^2}
\]
\[
\geq \min \left\{ \frac{a}{2}, \frac{\delta}{K^m} \right\} \int |k|^m |\hat{u}(k)|^2 \, dk + (c - \delta - \varepsilon) \| u \|^2_{L^2} - \frac{1}{4\varepsilon} \| u \|^2_{L^2}.
\]
Thus by choosing $\delta, \varepsilon$ to be small, we get the estimate (4.9).

To prove (4.7), we follow the same procedures as in the BBM and RBou cases. Let $u_\lambda \in H^m(\mathbb{R})$ be the solution of $(A^\lambda - k_\lambda) u_\lambda = 0$ with $k_\lambda \in \mathbb{R}$ and $\lim_{\lambda \to 0^+} k_\lambda = 0$. We normalize $u_\lambda$ by setting $\| u_\lambda \|_{L^2} = 1$. Then by (4.9), we have $\| u_\lambda \|_{H^m} \leq C$ and as before, after a renormalization $u_\lambda \to u_0 = u_{cx}$ in $H^m$. We have $\lim_{\lambda \to 0^+} \frac{I_1}{\lambda} = 0$, since
\[
k_\lambda \lambda (u_\lambda, u_{cx}) = \frac{A^\lambda - A^0}{\lambda} u_{cx} = \left( \frac{1}{\lambda - D} (f'(u_c) - \mathcal{M}) u_{cx} \right)
\]
\[
= \frac{1}{c} \left( (f'(u_c) - \mathcal{M}) u_{cx}, \frac{D}{\lambda - D} u_c \right)
\]
\[
- \frac{1}{c} \left( (f'(u_c) - \mathcal{M}) u_{cx}, u_c \right) = 0.
\]

Similarly as before, we can show that $u_\lambda = \bar{c}_\lambda u_{cx} + \lambda \bar{v}_\lambda$, with $\bar{c}_\lambda \to 1$, $\bar{v}_\lambda \to -\partial_c u_c$ in $H^m$, when $\lambda \to 0^+$. In the proof, we use the facts that
\[
w_\lambda(x) = \frac{A^\lambda - A^0}{\lambda} u_{cx} = \frac{1}{\lambda - D} (f'(u_c) - \mathcal{M}) u_{cx}
\]
\[
= \frac{D}{\lambda - D} u_{cx} \to -u_c, \text{ when } \lambda \to 0^+,
\]
and $\mathcal{L}_0 \partial_c u_c = -u_c$. Now
\[
k_\lambda \lambda (u_\lambda, u_{cx}) = \bar{c}_\lambda \left( \frac{A^\lambda - A^0}{\lambda} u_{cx}, u_{cx} \right) + \left( \frac{A^\lambda - A^0}{\lambda} \bar{v}_\lambda, u_{cx} \right) = \bar{c}_\lambda I_1 + I_2
\]
and
\[
I_1 = \left( \frac{w_\lambda(x)}{\lambda}, u_{cx} \right) + \left( \frac{1}{\lambda - D} (f'(u_c) - \mathcal{M}) u_{cx}, u_{cx} \right)
\]
\[
= -\frac{1}{c} \left( \frac{1}{\lambda - D} (f'(u_c) - \mathcal{M}) u_{cx}, u_c \right) + \frac{1}{c\lambda} ((f'(u_c) - \mathcal{M}) u_{cx}, u_c)
\]
\[
= -\frac{1}{c} ((c^\lambda - 1) u_c, u_c) - \frac{1}{c} (u_c, u_c),
\]

25
\[ I_2 = \left( \frac{A^3 - A^0}{\lambda} \overline{v}_\lambda, u_{cx} \right) = -\frac{1}{c} \left( \frac{D}{\lambda - D} (f' (u_c) - \mathcal{M}) \overline{v}_\lambda, u_c \right) \]

\[ \rightarrow -\frac{1}{c} \left( f' (u_c) - \mathcal{M} \right) \partial_c u_c, u_c = -\frac{1}{c} \left( c \partial_c u_c + u_c, u_c \right), \]

so

\[ \lim_{\lambda \to 0^+} \frac{k_\lambda}{\lambda^2} = \lim_{\lambda \to 0^+} \frac{\overline{\partial} I_1 + I_2}{(u_\lambda, u_{cx})} = -\left( \partial_c u_c, u_c \right) / (u_{cx}, u_{cx}) = -\frac{dP}{dc} / \|u_{cx}\|_{L^2}. \]

5 Discussions

(a) About the spectral assumption for \( L_0 \)

When \( \mathcal{M} = -\frac{D}{\lambda - D} \), the assumption (1.4) that \( \ker (L_0) = \{ u_{cx} \} \) is true because the second order ODE \( L_0 \psi = 0 \) has two solutions which decay and grow at infinity respectively, and thus \( u_{cx} \) is the only decaying solution. Moreover, the solitary waves in such case can be shown to be positive and single-humped. Thus by the Sturm-Liouville theory for second order ODE operators, \( n^- (L_0) = 1 \) since \( u_{cx} \) has exactly one zero. The proof of (1.4) for nonlocal dispersive operator \( \mathcal{M} \) is much more delicate. In (2, 5), (1.4) is proved for solitary waves of some KDV type equations, such as the intermediate long-wave equation (29) with

\[ f (u) = u^2 \text{ and } \alpha (k) = k \coth (kH) - H^{-1}. \]

The assumption (1.4) is related to the bifurcation of solitary waves, in the sense that \( \ker L_0 = \{ u_{cx} \} \) implies the nonexistence of secondary bifurcations at \( c \), that is, the solitary wave branch \( u_c (x) \) is locally unique. Even in cases of multiple branches of solitary waves, (1.4) is still valid in each branch. We note that \( \ker L_0 \) also monitors the changes of \( n^- (L_0) \) when \( c \) is changed. For example, when (1.4) is valid in a certain range of \( c \), \( n^- (L_0) \) must remain unchanged in this range. Since otherwise, by continuation there is a crossing of eigenvalues through origin at some \( c \), which increase the dimension of \( \ker L_0 \). This observation has been used in some problems (5, 37) to get \( n^- (L_0) \) for large waves from small waves for which \( n^- (L_0) \) is computable. At secondary bifurcation and turning points, the increase of \( \ker (L_0) \) signals the increase or decrease of \( n^- (L_0) \) when these transition points are crossed. One such example is the solitary waves for full water wave problem (37), for which the infinitely many turning points makes \( n^- (L_0) \) to increase without bound by a result of Plotnikov. The assumption (1.4) is also required in all existing proof of orbital stability (22, 14, 50).

(b) The sign-changing symbol

We assume \( \alpha (k) \geq 0 \) in our proof of Theorem 1. The proof can be easily modified to treat sign-changing symbols. Let \( -\gamma = \inf \alpha (k) < 0 \). Consider solitary wave solutions of KDV, BBM, and RBou type equations with

\[ c > \gamma, \ 1 - \frac{1}{c} > \gamma \ \text{and} \ 1 - \frac{1}{c^2} > \gamma \] (5.1)
The condition (5.1) on \( c \) is to ensure that the essential spectrum of \( L_0 \) lies in the positive axis, which is required to get decaying solitary waves, such as in [7] and [6] for fifth order KDV and Benjamin equations with \( \alpha (k) = -k^2 + \delta k^2 \) respectively. Denote \( \tilde{M} \) to be the multiplier operator with the nonnegative symbol \( \tilde{\alpha} (k) = \alpha (k) + \gamma \). The proof of Theorem 1 remains unchanged, by replacing \( M \) with \( \tilde{M} - \gamma \) and using the nonnegative symbol \( \tilde{\alpha} (k) \) in estimates. The same estimates still go through because of the condition (5.1). For sign-changing symbols, the solitary waves might be highly oscillatory in some parameter range ([7], [6]). It is conceivable that such oscillatory waves are energy saddle with \( n^- (L_0) \geq 2 \), whose stability cannot be studied by the traditional energy minimizer idea. Theorem 1 gives a sufficient condition for instability in such cases.

(c) Comparisons with the Evans function method

In [43], Pego and Weinstein use the Evans function technique to obtain the instability criterion \( dP/dc < 0 \) for the case \( M = -d^2/dx^2 \). In their paper, the eigenvalue problems (2.4), (3.3) and (4.3) are written as a first order system in \( x \), depending on the parameter \( \lambda \). The Evans function \( D (\lambda) \) is a Wronskian-like function whose zeros in the right half-plane correspond to unstable eigenvalues, and it measures the intersection of subspaces of solutions exponentially decaying at \( +\infty \) and \( -\infty \). This method was first introduced by J. W. Evans in a series papers including [21] and further studied in [1]. In [43], it is shown that \( D (\lambda) > 0 \) when \( \lambda > 0 \) is big enough, \( D (0) = D' (0) = 0 \) and

\[
D'' (0) = \text{sgn} \, dP/dc. \tag{5.2}
\]

If \( dP/dc < 0 \), then \( D (\lambda) < 0 \) and a continuation argument yield the vanishing of \( D (\lambda) \) at some \( \lambda > 0 \), which establishes a growing mode. A similar formula as (5.2) is derived in [18], for problems which can be written in a multi-symplectic form. However, there are several restrictions of the Evans function method: 1) Only the differential operators, that is, with polynomial symbols, can be treated, since the eigenvalue problems need to be written as a first order system. 2) The solitary waves must have the exponential decay. Moreover, certain assumptions for eigenvalues of the asymptotic systems are required in constructing the Evans function ([43], (0.6), (0.7)]. Such assumptions need to be checked case by case, and their relations to the properties of solitary waves are not very clear. By comparison, our approach apply to very general dispersive operators, in particular, nonlocal operators. We impose no additional assumptions on the solitary waves. For example, we allow slowly decaying, highly oscillatory or non-symmetric solitary waves. Our only assumption (1.4) is closed related to the bifurcation of solitary waves, and it appears to be rather natural in the stability theory. Moreover, the Evans function method can only be used for the one-dimensional problems, since otherwise the first order system can not be written. Our approach has no such restriction and might be useful in the multi-dimensional setting.

Lastly, we note that in Theorem [1] the instability is determined by both the sign of \( dP/dc \) and the oddness of \( n^- (L_0) \). The later information seems to not appear in the Evans function method ([43], [18]). When \( M \) is a differential operator and \( n^- (L_0) \) is even, suppose the Evans function can be constructed and the formula (5.2) is shown, then the instability criterion would be still \( dP/dc < 0 \), which is different from the
instability criterion $dP/dc > 0$ by Theorem 1. It would be interesting to clarify this issue. On possible such example is the oscillatory solitary waves (7) of the fifth order KDV equation.

(d) Some future problems

There are several open issues from our study.

(i) When the instability conditions in Theorem 1 are not satisfied, the stability of the solitary waves is unknown, except for the case when $n^- (L_0) = 1$ in the KDV and BBM case. Such solitary waves are energy saddles of an even negative index, whose stability is very subtle and not resolved even for the finite dimensional Hamiltonian systems. One might need to look for the oscillatory growing modes in such cases.

(ii) The nonlinear stability of solitary waves of energy saddles type is entirely open. This problem is important because of its direct relevance to the full water wave problem. Theorem 2 might be useful to study spectral stability as a first step. To apply it, one need to understand when the oscillatory instability can be excluded, which is related to (i).

(iii) Can we get nonlinear instability from linear instability, in the $L^2$ norm? This problem is open, even in the KDV and BBM cases where the nonlinear instability in the energy norm has been proved (14, 23). This problem is also relevant to full water waves and other problems for which the blow-up issue is concerned. The $L^2$ instability results could be used to distinguish the large scale instability of basic waves from the local blow-up instability due to the structure of the models.

6 Appendix

In this Appendix, we describe a different approach than [14] and [48] to get nonlinear instability for some dispersive wave models. In [14] and [48], the Liapunov functional method of [22] is extended to get nonlinear instability of solitary waves of KDV and BBM type equations, under the assumptions $dP/dc < 0$ and (1.5). For the KDV case, the Liapunov functional constructed in [14] becomes

$$A(t) = \int Y(x - x(t)) u(x, t) \, dx,$$

where $Y(x) = \int_{-\infty}^{x} y(z) \, dz$ and $y(x)$ is an energy decreasing direction under the constraint of the constant momentum $Q(u)$. By using the fact that the solitary wave considered is an (constrained) energy saddle with negative index one, it can be shown (22) that $A'(t) \geq \delta > 0$ in the orbital neighborhood of the solitary wave. The nonlinear instability would follow immediately if $A(t)$ is bounded, as considered in the abstract setting of [22]. However, $A(t)$ defined by (6.1) is not bounded because the function $Y(x)$ is not in $L^2$ if $\int y \, dx \neq 0$. To overcome this issue, in [14] it is shown that $A(t) \leq C(1 + t^\eta)$ with some $\eta < 1$, then the nonlinear instability still follows. Such an estimate is obtained by showing that the maximum of the anti-derivative of $u(x, t)$ has a sublinear growth. The same approach is used in [48], [40] and [20] (for KP equations), and the sublinear estimates are sometimes highly nontrivial to prove.
Below, we show that such an estimate can be avoided by using another approach, which was first introduced in [31] for a Schrödinger type problem.

The idea in [31] is to make a small correction to the (energy) decreasing direction $y(x)$ used in constructing the Liapunov functional $A(t)$. The new direction, still decreasing, has the additional property that its integral over $\mathbb{R}$ is zero. Then the new anti-derivative $Y(x) \in L^2$ and thus $A(t)$ is bounded which implies nonlinear instability. The correction is through the following lemma, which is a generalization of [31, Lemma 5.2].

**Lemma 6.1** For any $r(x) \neq 0 \in L^2(\mathbb{R})$, $c \in \mathbb{R}$ and $m \geq 1$, there exists a sequence $\{y_n\}$ in $H^m(\mathbb{R})$ such that

$$(1 + |x|)y_n(x) \in L^1(\mathbb{R}), \quad \int y_n(x) \, dx = c, \quad y_n \to 0 \text{ in } H^\infty(\mathbb{R}) \text{ and } (y_n, r) = 0.$$

**Proof.** We choose $\varphi(x) \in C^\infty_0(\mathbb{R})$ such that $\int \varphi(x) \, dx = c$. We claim that:

there exists $\psi(x) \in C^\infty_0(\mathbb{R})$ such that $(\psi_x, r) \neq 0$.

Suppose otherwise, for any $\psi(x) \in C^\infty_0(\mathbb{R})$, we have $(\psi_x, r) = 0$. Then $r_x = 0$ in the distribution sense and thus $r \equiv$ constant. But $r \in L^2$, so $r = 0$, which is a contradiction. Define

$$y_n = \frac{1}{n} \varphi\left(\frac{x}{n}\right) - a_n \psi_x(x),$$

with

$$a_n = \frac{\int \frac{1}{n} \varphi\left(\frac{x}{n}\right) r(x) \, dx}{(\psi_x, r)}.$$

Then $(y_n, r) = 0$ and

$$|a_n| \leq \frac{\left\|\frac{1}{n} \varphi\left(\frac{x}{n}\right)\right\|_{L^2} |r|_{L^2}}{|(\psi_x, r)|} = O\left(\frac{1}{\sqrt{n}}\right) \to 0,$$

when $n \to \infty$. Let $\varphi_n(x) = \varphi\left(\frac{x}{n}\right)$, then

$$\left\|\frac{1}{n} \varphi\left(\frac{x}{n}\right)\right\|_{H^\infty}^2 = \frac{1}{n} \left\|\varphi\right\|_{L^2}^2 + \frac{1}{n^2} \left\||D|^m \varphi\right\|_{L^2}^2 = \frac{1}{n} \left\|\varphi\right\|_{L^2}^2 + \frac{1}{n^{m+1}} \left\||D|^m \varphi\right\|_{L^2}^2 \to 0, \text{ when } n \to \infty,$$

where in the above we use the scaling formula

$$|D|^m \varphi_n(x) = \frac{1}{n^m} \left|D\right|^m \varphi\left(\frac{x}{n}\right)$$

as in the proof of Lemma[2.3]. Therefore, $y_n \to 0$ in $H^\infty(\mathbb{R})$, $(1 + |x|)y_n \in L^1$ and

$$\int y_n(x) \, dx = \int \frac{1}{n} \varphi\left(\frac{x}{n}\right) \, dx = \int \varphi(x) \, dx = c.$$
The lemma is proved. ■

We start with an (constrainted) energy decreasing direction \( y(x) \) with \((1+|x|)y(x) \in L^1\), that is,

\[
(\mathcal{H} y, y) < 0 \quad \text{and} \quad (y, Q'(u_c)) = 0,
\]

where \( \mathcal{H} \) is the second order variation of the augmented energy functional, for which the solitary wave is a critical point. Let \( H^{m} \) to be the energy space, that is, \( m \) is the power of the operator \( \mathcal{H} \). Choosing \( c = \int y \, dx \), \( r = Q'(u_c) \) in the above lemma, we get a sequence \( \{y_n\} \in H^m \) with the properties listed in the lemma. Defining \( \tilde{y}_n = y - y_n \), then we have

\[
(1 + |x|)\tilde{y}_n(x) \in L^1, \quad (\tilde{y}_n, P'(u_c)) = 0, \quad \int \tilde{y}_n \, dx = 0
\]

and \((\mathcal{H}\tilde{y}_n, \tilde{y}_n) < 0 \) when \( n \) is big enough. Thus for large \( n \), the function \( \tilde{y}_n \) is a new (constrainted) energy decreasing direction with zero integral. The Liapunov functional \( A(t) \) is defined as in (6.1) by using this new direction \( \tilde{y}_n \). By [14] p. 409, \( Y(x) = \int_{-\infty}^{x} \tilde{y}_n(z) \, dz \) is in \( L^2 \), thus \( A(t) \) is bounded and the nonlinear instability results.

Above approach has the following physical interpretation: if a solitary wave is not an energy minimizer under the constraint of constant momentum, neither is it even under the additional constraint of constant mass. This rather general idea could be useful in proving nonlinear instability of (constrainted) energy saddles with index one, for other similar problems.

Acknowledgement
