**ABSTRACT**

*Corcyra cephalonica* (Stainton), rice moth larvae were used for biodegradation of low density polyethylene (LDPE). The role of larval gut microorganisms in LDPE biodegradation was studied by force feeding the larvae with a cocktail of antibiotic solution. After force feeding, the larvae were left in contact with LDPE films. Larvae which were unfed with antibiotic solution were used as controls. Degradation rate was checked by measuring the weight loss after 20 day period of contact with LDPE films in insect rearing bottles. The DNA of both antibiotic fed and unfed larvae was isolated. There was no DNA band of antibiotic fed larvae which indicated the gut microorganisms were eliminated. Larvae fed with antibiotic digested 21 % and those which were unfed with antibiotic showed 25 % weight loss of LDPE films. We report the gut microorganisms were not solely responsible for biodegradation of LDPE. The digestive enzymes could also play a major role in digesting the plastic in insect’s gut.

**Keywords**: *Corcyra cephalonica*, rice moth larvae, low density polyethylene, antibiotic

**INTRODUCTION**

The rice moth, *Corcyra cephalonica* (Stainton) is a stored grain pest distributed all over Asia, Africa, Europe and North America [1]. It is a serious pest of rice and also feeds on other grains such as wheat, maize, groundnut, sorghum and millets [2]. *Corcyra cephalonica* is mostly used for mass production of biological agents and entomopathogenic nematodes [3].

Biodegradation of plastics by free living microorganisms have been reported till now but the efficiency of degradation was very low compared to the degradation rate by using insects and their gut microorganisms [4].

Biodegradation of plastics by using Indian meal worms, *Plodia interpunctella* was first reported by Yang et al. (2014). According to Yang et al. the gut microorganisms played a major role in polyethylene degradation. *Enterobacter asburiae* YT1 and *Bacillus sp.*
YP1 were capable of degrading PE in Indian meal worm’s gut [4]. Polystyrene (PS) biodegradation by yellow meal worms, *Tenebrio molitor* was studied by Yang et al. (2015) and reported the mass loss of 47.7% of PS over a 16 day test period [5]. Further the role of gut microorganisms and the effects on life cycle of yellow meal worms when fed with PS was also studied [6]. Biodegradation of Polyethylene (PE) by Greater wax moth larvae, *Galleria mellonella* was studied by Bombelli *et al.* (2017) wherein approximately 100 larvae consumed 92 mg of PE in 2 hours [7]. Hyun Gi Kong (2019) studied a detail mechanism of PE degradation in greater wax moth larvae. According to the study, gut microorganisms where not solely responsible for PE digestion in larval gut. Elimination of gut microorganisms by force feeding the larvae with a cocktail of antibiotics revealed that the larvae in the absence of gut microorganisms digested PE and was confirmed by Fourier Transform Infrared Spectroscopy (FTIR) and Gas-chromatography (GC) [8].

The present work aims to study the role of *Corcyra cephalonica* larvae and the gut microorganisms in LDPE degradation. Insects were reared on an artificial medium at 28 ± 1 °C, a relative humidity of 60 ± 5 % and 12 L : 12 D during the study period [9]. Among 50 larvae used for the study, 25 larvae were force fed with 9 µl of 1 mg/mL antibiotic mixtures (ampicillin, kanamycin and neomycin) prepared in sterile water and the remaining 25 larvae were used as controls. Both antibiotic fed and unfed larvae were left in contact with LDPE films cut in required sizes in two separate insect rearing bottles. The weight loss of LDPE was measured after 20 days and found that there was a gradual loss of LDPE weight as the larvae consumed the films. Interestingly, we found that even in the absence of gut microorganisms i.e. the larvae which were fed with antibiotic, consumed nearly equal amount of LDPE as compared with the controls.

**EXPERIMENTAL**

**Materials**

Low Density polyethylene (LDPE) bags were purchased from the local market of Dharwad, Karnataka, India. The bags were wiped with 1% Sodium dodecyl sulfate and 95% ethanol to remove the dust particles adhered to the bags.

**Rearing of insects in laboratory**

*Corcyra cephalonica* eggs (1cc) were procured from National Bureau of Agricultural Insect Resources (NBAIR), Bengaluru. The eggs were transferred into artificial medium which contained 2.5 kg of broken bajra, 75 g of groundnut seed powder, 5 g of yeast powder and 0.7 g of streptomycin sulphate. The growth of larvae was monitored regularly and the pupae were transferred to new chamber. The adults were transferred to an egg laying chamber supplemented with cotton swabs soaked in 5% honey. The eggs were again transferred to a new rearing chamber with artificial medium.

**The role of gut microorganisms in LDPE degradation**

The rice moth larvae, *Corcyra cephalonica* (Stainton) of 3rd instar were selected for the study. Totally 50 larvae were collected from the rearing chamber and starved for 48 hours. 25 larvae were transferred to a bottle containing accurately weighed LDPE films of 5 cm² sizes and the remaining 25 larvae were force fed with a cocktail of antibiotic solution. Ampicillin, kanamycin and neomycin of 1 mg/mL were prepared in sterile water and 9 µl of mixture was force fed to larvae. Briefly, a Durham’s tube was cut into small size of 2 cm and 3 µl of each antibiotic solution was added to it. Force feeding of antibiotic was performed by holding the head of the larva into the Durham’s tube for 15 seconds (Figure 1). The larvae after force feeding with antibiotic solution were transferred to a bottle
containing accurately weighed LDPE films of 5 cm² sizes.

Figure 1. Force feeding of antibiotic (9 µl of 1 mg/mL) solution to larvae

Isolation and culture of gut microorganisms (Culture dependent method)

Five larvae from each group were used for isolation of guts. The guts were isolated as described by Yang et al. (2014) with slight modifications. The larvae were surface sterilized with 70 % ethanol and sterile water. The guts were drawn out and added to 1.5 ml tubes containing 500 µl of sterile saline water (0.9 %). The tubes were vortexed briefly and the gut tissues were removed carefully with the help of sterile pipette and the suspension was used as an inoculum. 200 µl of the suspension from both the tubes was spread on nutrient agar (NA) plates and incubated at 37 °C for 24 hours [4].

Isolation of gut microbial DNA (Culture independent method)

Isolation of gut microbial DNA was performed as described by Kong et al. (2019) with slight modifications [8]. Briefly, single larva from both the groups was collected and the guts were drawn out. The guts were homogenized in 1.5 ml microcentrifuge tubes containing 400 µl of TE buffer (Tris 10 mM, EDTA 1 mM, pH 8.0) and sonicated (30 Amplitude, 1 s pulse). 20 µg/mL RNase, 0.5 % sodium dodecyl sulphate (SDS) and 10 µl of 100 µg/ml proteinase K was added to the tubes and incubated at 56 °C for 2 hours. An equal volume of phenol : chloroform : isoamylalcohol (25 : 24 : 1) was added to all the tubes and centrifuged at 10000 rpm for 15 minutes. A clear supernatant was transferred to a new 1.5 ml tube and extracted with an equal volume of Chloform : Isoamylalcohol (24 : 1). The tubes were vortexed briefly and centrifuged at 10000 rpm for 15 minutes. Supernatant was transferred to new 1.5 ml tube and DNA was precipitated by adding 0.6 volume chilled isopropanol. No DNA was precipitated in the larvae fed with antibiotic solution. The tubes were centrifuged at 10000 rpm for 5 minutes and supernatant was discarded. The DNA pellet from the antibiotic unfed larvae was washed with 70 % ethanol. The tube was centrifuged at 10000 rpm for 5 minutes and the pellet was dried and dissolved in 50 µl of sterile TE buffer and stored at 4 °C [8].

RESULTS AND DISCUSSION

Weight loss of LPDE films

The LDPE films from both the rearing bottles were collected after 20 days, wiped with 95 % ethanol and weighed accurately to determine the weight loss. Weight loss was calculated by using the following formula:

\[
\text{Weight loss (\%)} = \{\text{Initial weight} - \text{Final weight}\} / \text{Initial weight} \times 100
\]

Table 1 indicates the percentage of weight loss of LDPE films. The larvae force fed with antibiotic solution to eliminate the gut microorganisms showed 21 % of weight loss and the larvae which were not fed with antibiotic solution showed 25 %. Figure 2 represents the holes made by rice moth larvae on LDPE films during experimentation. Yang et al. (2015) carried out the similar experiments on Polystyrene (Styrofoam) by using *Tenebrio molitor*, a yellow meal worms and found 47.7 % of Styrofoam ingested by worms in a 16 day test period [5]. In a work
conducted by Bombelli et al. (2017), a total of 100 Greater wax moth larvae (*Galleria mellonella*), consumed 92 mg of polyethylene in a 2 hour period [7].

Table 1. Percentage of weight loss of LDPE films

|                          | Initial weight (g) | Final weight (g) | Weight loss (%) |
|--------------------------|--------------------|------------------|-----------------|
| LDPE films from antibiotic unfed larvae bottle | 1.0                | 0.75             | 25              |
| LDPE films from antibiotic fed larvae bottle     | 1.0                | 0.79             | 21              |

Culture dependent method to identify the role of gut microorganisms

The larvae which were force fed with antibiotic solution showed no growth, whereas those which were not fed with antibiotic solution showed the growth of bacterial colonies on NA plates as shown in Figure 3. Ampicillin was used to eliminate Gram negative bacteria, kanamycin for Gram positive bacteria and neomycin for the elimination of yeast from the gut of the larvae. Kong et al. (2019) reported the similar studies on Greater wax moth, *Galleria mellonella* larvae to know the role of gut microorganisms in polyethylene degradation [8].

Figure 3. Nutrient agar plates: Antibiotic fed larval gut content (A) and Antibiotic unfed larval gut content (B)

Larval gut microbial DNA

There was no DNA in antibiotic fed larvae. However, both the elutions were run on 0.8 % agarose gel. The larvae fed with antibiotic showed no DNA band whereas those which were not fed with antibiotic showed the DNA band (Figure 4). Studies conducted by Kong et al. (2019) on Greater wax moth larvae indicated that the gut microorganisms were not solely responsible for polyethylene and beeswax degradation [8].

CONCLUSION

The aim of this study was to identify the role of gut microorganisms of Corcyra cephalonica larvae in LDPE biodegradation in their guts. Weight loss method indicated that the gut microorganisms are not solely responsible for LDPE digestion in insect’s gut. An average of 23% weight loss of LDPE was observed in both antibiotic fed and untreated larvae. The gut content of the larvae which were force fed with antibiotic and spread on NA plates showed no colonies and those which were not fed with antibiotic showed bacterial colonies after 24 hours of incubation. This indicated that the gut microorganisms were susceptible to antibiotic solution. The DNA bands were not observed in the larvae which were fed with antibiotic solution. This indicated that the larvae were able to function and digest LDPE with little or no role of gut microorganisms. However, this is the first report on biodegradation of low density polyethylene by rice moth larvae. The future work aims to study the mechanisms involved in the gut of rice moth larva in degrading the plastic.
