Abstract

A natural problem in high-dimensional inference is to decide if a classifier \( f : \mathbb{R}^n \rightarrow [-1, 1] \) depends on a small number of linear directions of its input data. Call a function \( g : \mathbb{R}^n \rightarrow [-1, 1] \), a linear \( k \)-junta if it is completely determined by some \( k \)-dimensional subspace of the input space. A recent work of the authors showed that linear \( k \)-juntas are testable. Thus there exists an algorithm to distinguish between:

1. \( f : \mathbb{R}^n \rightarrow \{ -1, 1 \} \) which is a linear \( k \)-junta with surface area \( s \),
2. \( f \) is \( \epsilon \)-far from any linear \( k \)-junta,

where the query complexity of the algorithm is independent of the ambient dimension \( n \).

Following the surge of interest in noise-tolerant property testing, in this paper we prove a noise-tolerant (or robust) version of this result. Namely, we give an algorithm which given any \( c > 0, \epsilon > 0 \), distinguishes between

1. \( f : \mathbb{R}^n \rightarrow \{ -1, 1 \} \) has correlation at least \( c \) with some linear \( k \)-junta with surface area \( s \).
2. \( f \) has correlation at most \( c - \epsilon \) with any linear \( k \)-junta.

Our query complexity is qualitatively the same, i.e., remains independent of \( n \) and is polynomially dependent on \( k \). A major motivation for studying Linear Junta Testing come from statistical models where it is crucial to allow noise. In the language of model compression, our results show statistical models can be “compressed” in query complexity that depends only on the size of the desired compression, when the compression is a linear Junta.

1 Introduction

To motivate our setting, consider the classical notion of a Boolean junta: a function \( f : \{-1, 1\}^n \rightarrow \{-1, 1\} \) is said to be a \( k \)-junta if there are some \( k \) coordinates \( i_1, \ldots, i_k \in [n] \) such that \( f(x) \) only depends on \( x_{i_1}, \ldots, x_{i_k} \). The fundamental results for testing juntas were obtained more than a decade ago; more recently, spurred by motivation from several directions, several variants have appeared. Most importantly for this work are the notions of tolerant testing, in which we estimate the distance to the class of juntas (as opposed to the usual testing, where we are simply testing membership); and linear juntas, a natural continuum generalization of Boolean juntas. In the current work, we combine these two perspectives and show that linear juntas are noise-tolerantly testable.

1.1 Tolerant Junta Testing

Recall that a property testing algorithm for a class of functions \( C \) is an algorithm which, given oracle access to an \( f : \{-1, 1\}^n \rightarrow \{-1, 1\} \) and a distance parameter \( \epsilon > 0 \), satisfies

1. If \( f \in C \), then the algorithm accepts with probability at least 2/3;

2. If \( \text{dist}(f, g) \geq \epsilon \) for every \( g \in C \), then the algorithm rejects with probability at least 2/3. Here \( \text{dist}(f, g) = \Pr_{x \in \{-1, 1\}^n}[f(x) \neq g(x)] \).

The principal measure of the efficiency of the algorithm is its query complexity. Also, the precise value of the confidence parameter is irrelevant and 2/3 can be replaced by any constant 1/2 < \( c < 1 \).

Fischer et al. [19] were the first to study the problem of testing \( k \)-juntas and showed that \( k \)-juntas can be tested with query complexity \( O(k^2/\epsilon) \). The crucial feature of their algorithm is that the query complexity is independent of the ambient dimension \( n \). Since then, there has been a long line of work on testing juntas [6, 5, 6, 14, 12] and it continues to be of interest. The flagship result is that \( k \)-juntas can be tested with \( O(k/\epsilon) \) queries and this is tight [6, 14]. While the initial motivation to study this problem came from long-code testing [3, 31] (related to PCPs and inapproximability), another strong motivation comes from the feature selection problem in machine learning (see, e.g. [8, 9]).

Tolerant testing The definition of property testing above requires the algorithm to accept if and only if \( f \in C \). However, for many applications, it is important consider a noise-tolerant definition of property testing. In particular, Parnas, Ron and Rubinfeld [30] introduced the following definition of noise tolerant testers.

Definition 1.1. For constants \( 1/2 > c_u > c_\ell \geq 0 \) and a function class \( C \), a \((c_u, c_\ell)\)-noise tolerant tester for \( C \) is an algorithm which given oracle access to a function \( f : \{-1, 1\}^n \rightarrow \{-1, 1\} \)

1. accepts with probability at least 2/3 if \( \min_{g \in C} \text{dist}(f, g) \leq c_\ell \).

2. rejects with probability at least 2/3 if \( \min_{g \in C} \text{dist}(f, g) \geq c_u \).

Further, a tester which is noise tolerant for any (given) \( c_u > c_\ell \geq 0 \) is said to be a “fully noise tolerant” tester.

The restriction \( c_u, c_\ell < 1/2 \) comes from the fact that most natural classes \( C \) are closed under complementation – i.e., if \( g \in C \), then \( -g \in C \). For such a class \( C \) and for any \( f \), \( \min_{g \in C} \text{dist}(f, g) \leq 1/2 \). Further, note that the standard notion of property testing corresponds to a \((0, 0)\)-noise tolerant tester.

The problem of testing juntas becomes quite challenging in the presence of noise. Parnas et al. [30] observed that any tester whose (individual) queries are uniformly distributed are inherently noise tolerant in a very weak sense. In particular, [17] used this observation to show that the junta tester of [19] is in fact a \((\epsilon, \text{poly}(\epsilon/k))\)-noise tolerant tester for \( k \)-juntas – note that \( c_\ell \) is quite small, namely \( \text{poly}(\epsilon/k) \). Later, Chakraborty et al. [11] showed that the tester of Blais [6] yields a \((C\epsilon, \epsilon)\) tester (for some large but fixed \( C > 1 \)) with query complexity \( \exp(k/\epsilon) \).
Recently, there has been a surge of interest in tolerant junta testing. On one hand, Levi and Waingarten showed that there are constants $1/2 > \epsilon_1 > \epsilon_2 > 0$ such that any non-adaptive $(\epsilon_1, \epsilon_2)$ tester requires $\tilde{\Omega}(k^2)$ non-adaptive queries. Contrast this with the result of Blais [6] who showed that there is non-adaptive tester for $k$-juntas with $O(k^{3/2})$ queries when there is no noise. In particular, this shows a gap between testing in the noisy and noiseless case.

In the opposite (i.e., algorithmic) direction a sequence of recent works improved on the results of [11]. First, Blais et al. [7] improved on the results of [11] by obtaining a small and explicit value of $C$. Finally, De, Mossel and Neeman [16] gave a fully noise tolerant tester for $k$-juntas on the Boolean cube with query complexity $O(2^k \cdot \text{poly}(k/\epsilon))$.

1.2 Linear Junta Testing

In a recent work, De, Mossel and Neeman [15] initiated the study of property testing of linear juntas. A function $f : \mathbb{R}^n \to [-1, 1]$ is said to be a linear $k$-junta if there are $k$ unit vectors $u_1, \ldots, u_k \in \mathbb{R}^n$ and $g : \mathbb{R}^k \to [-1, 1]$ such that $f(x) = g(u_1 \cdot x, \ldots, u_k \cdot x)$. In other words, $f$ is a linear $k$-junta if there is a subspace $E := \text{span}(u_1, \ldots, u_k)$ of $\mathbb{R}^n$ such that $f(x)$ depends only on the projection of $x$ on the subspace $E$. The class of linear $k$-juntas is the $\mathbb{R}^n$-analogue of the class of $k$-juntas on the Boolean cube.

We note that the family of linear $k$-juntas includes important classes of functions that have been studied in the learning and testing literature. Notably it includes:

- Boolean juntas: If $h : \{-1, 1\}^n \to \{-1, 1\}$ is a Boolean junta, then $f(x) : \mathbb{R}^n \to \{-1, 1\}$ defined as $f(x) = h(\text{sgn}(x_1), \ldots, \text{sgn}(x_n))$ is a linear $k$-junta.

- Functions of halfspaces: Linear $k$-juntas include as a special case both halfspaces and intersections of $k$-halfspaces. The testability of halfspaces was studied in [25] [26] [34].

The focus of the paper is on property testing of linear $k$-juntas. Observe that to formally define a testing algorithm, we need to define a notion of distance between functions $f$ and $g$ on $\mathbb{R}^n$. In this work, we will use the $L^2(\gamma)$ metric, where $\gamma$ is the standard Gaussian measure. That is, the distance between $f$ and $g$ is $(\mathbf{E}_{x \sim \gamma}[(f(x) - g(x))^2])^{1/2}$. Note that this reduces to $2 \Pr_{x \sim \gamma}[f(x) \neq g(x)]$ when $f$ and $g$ are Boolean functions. The choice of the standard Gaussian measure is well-established in the areas of learning and testing [25] [22] [28] [2] [13] [21] [37] [18] [20]. It is particularly natural in our setup since the Gaussian measure is invariant under many linear transformations, e.g., all rotations.

De, Mossel and Neeman [15] obtained an algorithm for testing linear-$k$-juntas: given query access to $f : \mathbb{R}^n \to [-1, 1]$, it makes $\text{poly}(k \cdot s/\epsilon)$ queries and distinguishes between

1. $f$ is a linear-$k$-junta with surface area at most $s$ versus
2. $f$ is $\epsilon$-far from any linear $k$-junta.

Here surface area of $f$ refers to the Gaussian surface area of $f$ [23] and is the surface area of the set $f^{-1}(1)$ weighted by $\gamma_n$, the standard normal measure – see Definition [2.7] for the precise definition. Further, [15] showed that a polynomial dependence on $s$ is necessary for any non-adaptive tester and consequently, an $\Omega(\log s)$ dependence is necessary for any tester\footnote{Recall that in a non-adaptive tester, the query points are chosen independently of the target $f$.}. Informally, without any smoothness assumption a linear junta (even a linear 1-junta on $\mathbb{R}^2$) can look arbitrarily random to any finite number of queries. Crucially, [15] achieves a query complexity which is independent of the ambient dimension $n$ – thus, qualitatively matching the guarantee for junta testing on the Boolean cube.
1.3 Our Results: Noise tolerant testing of linear-juntas

In this paper, our focus is on the problem of noise tolerant testing of linear juntas. The original motivation of \cite{15} was for dimension reduction in statistical and ML models involving real valued data. Modern ML models are often overparametrized, but are nevertheless suspected to output a predictor that is low-dimensional in some sense. The classical notion of juntas is not for measuring dimensionality here, because there is no natural choice of basis both in many statistical models including PCA, ICA, kernel learning, or deep learning. This motivates the notion of a linear junta. The problem of testing linear-juntas is thus closely related to the problem of model compression in machine learning, whose goal is to take a complex predictor/classifier function and to output a simpler predictor/classifier (see e.g. \cite{10}). Model compression is extensively studied in the context of deep nets, see e.g., \cite{1}, and follow up work, where the models are often rotationally invariant (with the caveat that the regularization often used in optimization might not be). Thus as a motivating example, \cite{15} asked if given a complex deep net classifier, is there a classifier that has essentially the same performance and depends only on $k$ of the features? Observe that this is essentially the same question as asking whether the deep net classifier is a linear $k$-junta.

The main shortcoming of the motivation in \cite{15} is that it is unrealistic to expect that in any of the statistical and ML models considered, the function constructed will be exactly identical to a function of a few linear direction. Rather, we only expect that the function will be correlated with a function of a few directions; this is the tolerant testing problem, and – as evidenced by the long history of tolerant testing in the Boolean case – it is much more challenging.

The main result of this paper is a fully noise tolerant tester for $k$-linear juntas over the Gaussian space whose query complexity is independent of the ambient dimension $n$. In particular, we prove the following:

**Theorem 1.2.** There is an algorithm Robust-linear-junta-Boolean which given parameters $1/2 > c_u > c_\ell > 0$, junta arity $k$ and surface area parameter $s$ and oracle access to $f : \mathbb{R}^n \to \{-1, 1\}$ distinguishes between the following cases:

1. There is a linear-$k$-junta $g$ with surface area at most $s$ such that $\text{dist}(f, g) \leq c_\ell$.
2. For all linear-$k$-juntas $g$, $\text{dist}(f, g) \geq c_u$.

The query complexity of the tester is $k^{\text{poly}(s/\epsilon)}$ where $\epsilon = c_u - c_\ell$ and tester makes non-adaptive queries.

Note that qualitatively this result implies the main result of \cite{15} – thus a dependence on $s$ is necessary, though presumably, one can achieve a polynomial dependence on $s$. The above result is in fact a consequence of a more general result we prove for bounded functions. For this, we will need a notion of smoothness which is in turn defined on the basis of Ornstein-Uhlenbeck noise operator (henceforth, referred to as the noise operator) on the Gaussian space. We refer the reader to Definition 2.4 for the precise definition of the noise operator.

It is not hard to see that tolerant testing is essentially equivalent to estimating the maximum correlation between a function and a class. In particular, Theorem 1.2 follows from the following result about estimating correlation. Here (and in most of this work), it is more convenient to consider functions with values in $[-1, 1]$. For these functions, we need a more general notion of smoothness: we will define the notion of $s$-smooth functions later (in Definition 2.6): for now, we just note that it includes both Lipschitz functions and Boolean functions with bounded surface area.

**Theorem 1.3.** There is an algorithm Correlation-smooth-junta which, given parameters $\epsilon > 0$, junta arity $k$ and smoothness parameter $s$ and oracle access to $f : \mathbb{R}^n \to [-1, 1]$, outputs an estimate $\hat{\rho}_{\mathbb{R}^n, k, s}(f)$ with the following guarantee:

$$|\hat{\rho}_{\mathbb{R}^n, k, s}(f) - \rho_{\mathbb{R}^n, k, s}(f)| \leq \epsilon.$$  

Here $\rho_{\mathbb{R}^n, k, s}(f)$ is the maximum correlation of $f$ with any $s$-smooth $k$-linear junta. The query complexity of the algorithm is $k^{\text{poly}(s/\epsilon)}$. 

The key feature of this theorem is that, as with the earlier results, the query complexity is completely independent of the ambient dimension $n$.

### 1.3.1 Finding the linear-invariant structure

Given the previous theorem it is natural to ask for more, i.e., not just test if the function is a linear-junta but also find a junta in number of queries that depends only on $k$ and $s$ (but not on $n$) that has almost maximal correlation with $f$. In other words, the goal is to find, with query complexity independent of $n$, a function $g : \mathbb{R}^k \to \{-1, 1\}$ such that there exists a projection matrix $A : \mathbb{R}^n \to \mathbb{R}^k$ and such that the correlation between $f$ and $g(Ax)$ is at least $\rho_{\mathbb{R}^n,k,s}(f) - \epsilon$.

In the case where $f$ is a linear $k$-Junta with bounded surface area, i.e., $\rho_{\mathbb{R}^n,k,s}(f) = 1$, [15] provided such an algorithm with query complexity that is exponential in $k$. We note that in [15] it was incorrectly stated (without proof) that the exponential dependence on $k$ is necessary.

Here we improve on the result from [15] by showing that this can be done in the tolerant setting in sampling complexity that is polynomial in $k$ (for fixed $s$ and $\epsilon$).

**Theorem 1.4.** There is an algorithm Learn-invariant-structure which, given parameters $\epsilon > 0$, junta arity $k$ and smoothness parameter $s$ and oracle access to $f : \mathbb{R}^n \to \{-1, 1\}$, outputs $g : \mathbb{R}^k \to \{-1, 1\}$ so that the following holds: there exists an orthonormal set of vectors $w_1, \ldots, w_k \in \mathbb{R}^n$ such that

$$E[|f(x) - g(w_1, x), \ldots, g(w_k, x)|] = O(\epsilon).$$

The query complexity of the algorithm is $k^{\text{poly}(s/\epsilon)}$.

Informally, the theorem states that it is possible to find the “linear-invariant” structure (i.e., the structure up to unitary transformation) of a Junta that is almost optimally correlated with $f$ in number of queries that depends on $s$ and $k$. We note that one cannot hope to output the relevant directions $w_1, \ldots, w_k$ explicitly even describing these directions will require $\omega(n)$ bits of information and thus, at least those many queries.

Theorems 1.3 and 1.4 may be interpreted as showing that one can find the best compression of a statistical model in terms of a linear Junta in query complexity that does not depend on the ambient dimension $n$ (of course writing/finding the actual representation of such a Junta in terms of the original variables will depend on ambient dimension $n$).

### 1.4 Techniques

The techniques of the current paper build on those of [15]. We briefly recap the main ideas of [15], restricted for now to the non-tolerant setting:

I. If we sample $T = \text{poly}(k/\epsilon)$ random points $x_1, \ldots, x_T$ from the standard Gaussian measure $\gamma_n$ and let $E = \text{span}(\nabla f(x_1), \ldots, \nabla f(x_T))$, then if $f$ is a linear $k$-Junta then with high probability, $f$ has correlation $1 - \epsilon$ with some linear $k$-Junta defined on the space $E$.

II. For each $x, z$, it is possible to estimate, in number of samples polynomial in $k$, quantities such as $\langle z, \nabla f(x) \rangle$ and $\langle \nabla f(x_i), \nabla f(x_j) \rangle$ up to small error. Thus, for a randomly chosen $z \sim \gamma_n$, we can (implicitly, in a sense to be made precise later) compute the orthogonal projection of $z$ on $E$. (Note that a naive estimation of $\nabla f(x)$, or even $\langle \nabla f(x_1), \nabla f(x_2) \rangle$ requires a number of samples that depends on $n$.)

Observe that the implicit projection allows [15] to effectively reduce the dimension of the ambient space to $T = \text{poly}(k/\epsilon)$, which is independent of $n$. We then take an $\epsilon$-net of linear $k$-juntas over $E$ with surface area $s$. The size of this net depends only on $s$, $k$ and $\epsilon$. For each function in the net, one can estimate its distance to $f$; by iterating over all functions in the net, one can check if $f$ is close to a linear $k$-Junta. This last step is different from the one in [15], and in fact it is slightly worse. By following the ideas in the current paper, one can show that it gives a tester for with query complexity of $k^{O(\epsilon^2/\epsilon^2)}$. The advantage of the modification, however, is that it yields a method that is more robust to noise.
Adding tolerance. In adapting the outline above to the setting of tolerant testing, the main challenge is to 
imitate step I above. Our main structural result roughly shows that if \( f \) has correlation \( c \) with some linear \( k \)-junta of surface area at most \( s \), then with high probability \( f \) is at least \( c - \epsilon \) correlated with an \( s \)-smooth linear \( k \)-junta defined on \( E \). In fact, we need to define \( E \) more carefully than what is outlined above, and a good error analysis is crucial. If we were to combine our new structural result with a naive error analysis, it would give a query complexity that is exponential in \( \text{poly}(k) \).

The proof of our structural result is non-trivial. At the intuitive level it is related to the idea of using SVD for PCA. In our case, we have a function, rather than a collection of data, and the right geometric information is encoded by gradients (of a smoothed version of this function). The procedure of using SVD to extract informative directions from the data can be thought of as “Gradient Based PCA”. The proof that this procedure actually extracts the relevant dimensions requires combining linear algebraic and Poincare style geometric estimates in just the right way. Another challenge comes from the fact that gradients are only approximate due to sampling effect. We use results from random matrix theory to control the effect of sampling.

The methodology of Gradient Based PCA also allows us to improve on the results of [15] in the noiseless case for finding an approximation of the Junta. This has to do with the fact that the results of [15] used a more naive Gram–Schmidt based process to extract the linear structure which resulted in exponential query complexity, compared with the polynomial query complexity we achieve in the current work.

Another key new ingredient of this current work is the net argument outlined above. We show that the class of \( s \)-smooth linear \( k \) juntas has an \( \epsilon \)-net of size \( \exp \exp((s^2 \log k)/\epsilon^2) \). For each function in the net, we can use the implicit projection algorithm to compute the correlation between this function and \( f \) up to error \( \epsilon \). The maximum of these correlations gives a good estimate of the best correlation between \( f \) and any linear \( k \)-junta with surface area \( s \). This concludes the proof sketch of Theorem 1.3.

We note that there is a high-level similarity between the current proof and the proof that Boolean juntas are tolerant testable [16]. Both strategies are based on oracle access to influential “directions” followed by a search for juntas depending only on those influential directions. In the Boolean case, the “directions” are influential variables, while here the directions are given by gradients of the function \( f \). Note, however, that the Boolean case is easier, since the coordinates on the Boolean cube are automatically orthogonal, while in the continuous setup, “relevant directions” as sampled from data are often not orthogonal and indeed can be close to parallel. This is one of the major reasons we needed to introduce and analyze the methodology of gradient based PCA.

2 Preliminaries

In this section, we list some useful definitions and technical preliminaries. We begin with some definitions and properties of projections and averages.

**Definition 2.1.** For a subspace \( E \) of \( \mathbb{R}^n \), we denote by \( \Pi_E : \mathbb{R}^n \to \mathbb{R}^n \) the orthogonal projection onto \( E \). For a subspace \( E \) and \( f : \mathbb{R}^n \to \mathbb{R} \), we define the operator \( \mathcal{A}_E \) as \( \mathcal{A}_E f(x) = E_z \gamma_n[f(\Pi_E x + \Pi_E z)] \), where \( \gamma_n \) is the standard \( n \)-dimensional Gaussian measure.

Finally, for any subspace \( E \), we define \( \mathcal{F}_E = \{ f : \text{if } \Pi_{E}x = \Pi_{E}z, \text{then } f(x) = f(z) \} \).

One way to understand the operator \( \mathcal{A}_E \) is that it averages \( f \) on the directions orthogonal to the subspace \( E \). The next lemma lists some useful properties of the operators \( \Pi_E \) and \( \mathcal{A}_E \). Let \( \mathcal{C}^1_b(\mathbb{R}^n) \) be the class of differentiable functions \( f \) such that \( f(x) \) and \( \nabla f(x) \) are bounded.

**Lemma 2.2.** For any \( f \in \mathcal{C}^1_b(\mathbb{R}^n) \), any subspaces \( E \subseteq E' \subseteq \mathbb{R}^n \), and any \( x \in \mathbb{R}^n \), the following hold:

1. If \( \Pi_{E}z = \Pi_{E}x \) then \( \mathcal{A}_E f(x) = \mathcal{A}_E f(z) \). In other words, \( \mathcal{A}_E f \in \mathcal{F}_E \).
2. \( \nabla \mathcal{A}_E f(x) = E_z[\Pi_{E}x \nabla f(\Pi_{E}x + \Pi_{E}z)] \)
3. \( \mathcal{A}_E \mathcal{A}_{E'} f(x) = (\mathcal{A}_E f)(x) \)
4. For all \( g \in \mathcal{J}_E \), \( \mathbb{E}_x[g(x)\mathcal{A}_E f(x)] = \mathbb{E}_x[g(x)f(x)] \)

5. For all \( g \in L^2(\gamma) \), \( \mathbb{E}_x[(\mathcal{A}_E f)(x)g(x)] = \mathbb{E}_x[f(x)(\mathcal{A}_E g)(x)]. \)

Note that parts [1] and [4] can be interpreted as saying that \( \mathcal{A}_E f \) is the orthogonal projection (in the \( L^2(\gamma) \) sense) of \( f \) onto \( \mathcal{J}_E \).

**Proof.**

1. Part [1] is immediate from the definition of \( \mathcal{A}_E \).

2. To prove part [2], fix \( v \in \mathbb{R}^n \). Then
   \[
   (\mathcal{A}_E f)(x) - (\mathcal{A}_E f)(x-v) = \mathbb{E}_x[f(\Pi_E x + \Pi_E z) - f(\Pi_E x - \Pi_E v + \Pi_E z)]
   \]

   Replacing \( v \) by \( hv \) and sending \( h \to 0 \), we obtain (and there is no trouble exchanging the limit and the expectation, because \( f \) is Lipschitz)
   \[
   (\nabla_x \mathcal{A}_E f)(x) = \mathbb{E}_x[\nabla_x f(\Pi_E x + \Pi_E z)].
   \]

   This proves the second item.

3. Part [3] follows from the fact that if \( E \subset E' \) then \( \Pi_E \Pi_{E'} = \Pi_{E'} \) and \( \Pi_E \Pi_{E'} z = 0 \) for every \( z \). Indeed, if \( z \) and \( z' \) are independent standard Gaussian variables then
   \[
   (\mathcal{A}_E \mathcal{A}_{E'} f)(x) = \mathbb{E}_{xx'}[f(\Pi_E (\Pi_{E'} x + \Pi_{E'} z') + \Pi_E z)] = \mathbb{E}_x[f(\Pi_E x + \Pi_E z)] = (\mathcal{A}_E f)(x).
   \]

4. For Item [4] let \( z \) and \( z' \) be standard Gaussian variables. Since \( g \in \mathcal{J}_E \), we have \( g(z) = g(\Pi_E z + \Pi_E z') \).
   Hence,
   \[
   \mathbb{E}_x[g \mathcal{A}_E f] = \mathbb{E}_{xx'}[g(z)f(\Pi_E z + \Pi_E z')] = \mathbb{E}[g(\Pi_E z + \Pi_E z')f(\Pi_E z + \Pi_E z')].
   \]

   Since \( \Pi_E z + \Pi_E z' \) has the same distribution as \( z \), the claim follows.

5. Item [5] follows from applying claim [4] twice:
   \[
   \mathbb{E}_x[(\mathcal{A}_E f)(x)g(x)] = \mathbb{E}_x[(\mathcal{A}_E f)(x)(\mathcal{A}_E g)(x)] = \mathbb{E}_x[f(x)(\mathcal{A}_E g)(x)]. \quad \square
   \]

   As an immediate consequence of the properties above, we have the following two basic properties of \( \nabla \mathcal{A}_E f \):

**Claim 2.3.**

1. \( \mathbb{E}_x[\nabla \mathcal{A}_E f(x)] = \mathbb{E}_x[\Pi_E \nabla f(x)] \).

2. \( \mathbb{E}_x[||\nabla \mathcal{A}_E f(x)||^2] \leq \mathbb{E}_x[||\Pi_E \nabla f(x)||^2] \).

**Proof.** Item [1] follows by averaging over Item [2] from Lemma [2.2]. To get Item [2], first observe that by Jensen’s inequality (applied on Item [2] from Lemma [2.2]), we have
   \[
   ||(\nabla \mathcal{A}_E f)(x)||^2 \leq \mathbb{E}_x[||\Pi_E \nabla f(\Pi_E x + \Pi_E z)||^2].
   \]

   Averaging over \( x \sim \gamma \) and observing that the distribution of \( \Pi_E x + \Pi_E z \) is the same as that of \( x \), we have Item [2] \quad \square
2.1 Smoothness and Juntas

The notion of smoothness that we will use in this work depends on the notion of Gaussian noise. In particular, we use the following Gaussian noise operator:

**Definition 2.4.** For \( t \geq 0 \) and \( f \in L_2(\gamma_n) \), we define \( P_t f : \mathbb{R}^n \to \mathbb{R} \) as
\[
P_t f(x) = \mathbb{E}_y [f(e^{-t}x + \sqrt{1-e^{-t^2}}y)].
\]
The operator \( P_t \) forms a semigroup, i.e., \( P_t P_r f = P_{t+r} f \). Further, for \( t > 0 \), \( P_t f \) is infinitely differentiable.

We recall here a basic property of this noise operator – namely, that \( P_t \) makes any bounded function Lipschitz, a fact that can be derived, for example, from (2.3) in [24].

**Fact 2.5.** For any \( f : \mathbb{R}^n \to [-1, 1] \) and any \( t > 0 \), \( P_t f \) is \( \sqrt{C} \)-Lipschitz for an absolute constant \( C \).

Now we come to the notion of \( s \)-smooth functions:

**Definition 2.6.** A function \( f : \mathbb{R}^n \to [-1, 1] \) is referred to as \( s \)-smooth if for all \( t > 0 \),
\[
\mathbb{E}[|f(x) - P_t f(x)|] \leq s \sqrt{t}.
\]
In this case, we say that \( \text{Sm}(f) \leq s \).

To help illustrate the definition, let us recall the notion of Gaussian surface area:

**Definition 2.7.** For a Borel set \( A \subseteq \mathbb{R}^n \), we define its Gaussian surface area, denoted by \( \Gamma(A) \) to be
\[
\Gamma(A) = \lim_{\delta \to 0} \inf \frac{\text{vol}(A_\delta \setminus A)}{\delta}.
\]
Here \( A_\delta \) denotes the set of points which are at Euclidean distance at most \( \delta \) the set \( A \).

The next proposition shows that the class of \( s \)-smooth functions functions of bounded surface area. Later, we will also show that the notion of \( s \)-smoothness is equivalent to a certain decay in the Hermite coefficients (which can also be used to show that if \( \text{Sm}(f) \leq C \mathbb{E}[||\nabla f||^2] \), so for example Lipschitz functions are \( s \)-smooth).

**Proposition 2.8.**

1. If \( f : \mathbb{R}^n \to [-1, 1] \) with surface area at most \( \frac{s \sqrt{n}}{2} \), then \( \text{Sm}(f) \leq s \).

2. Let \( E \) be any subspace of \( \mathbb{R}^n \). If \( f \) is \( s \)-smooth, then so is \( \mathcal{A}_E f \).

**Proof.**

1. Part [1] was proved by Pisier [33] and Ledoux [23].

2. To prove Part [2] observe that the operators \( \mathcal{A}_E \) and \( P_t \) commute. Thus,
\[
\mathbb{E}[|\mathcal{A}_E f(x) - P_t \mathcal{A}_E f(x)|] = \mathbb{E}[|\mathcal{A}_E f(x) - \mathcal{A}_E P_t f(x)|].
\]
However, Jensen’s inequality implies that for any \( f \) and \( g \),
\[
\mathbb{E}_x[|\mathcal{A}_E f(x) - \mathcal{A}_E g(x)|] \leq \mathbb{E}_x[|f(x) - g(x)|].
\]
This finishes the proof.

We now define the class of \( s \)-smooth linear \( k \)-juntas.

**Definition 2.9.** For a subspace \( E \) of \( \mathbb{R}^n \), parameter \( s > 0 \) and \( k \in \mathbb{N} \), we say \( f : \mathbb{R}^n \to [-1, 1] \in \mathcal{F}_{E,k,s} \) if

- There is a subspace \( E' \subseteq E \) of dimension \( k \) such that \( f \in \mathcal{F}_{E'} \).

- \( f \) is \( s \)-smooth.

**Definition 2.10.** For a function \( h : \mathbb{R}^n \to [-1, 1] \), a subspace \( E \) of \( \mathbb{R}^n \), \( k \in \mathbb{N} \) and \( s > 0 \), we define
\[
\rho_{E,k,s}(h) = \max_{\phi \in \mathcal{F}_{E,k,s}} \mathbb{E}[\phi(x) \cdot h(x)].
\]
2.2 Useful results about matrices

**Definition 2.11.** Let \( B \in \mathbb{R}^{m \times n} \) matrix. Then, the singular value decomposition (SVD) of \( B \) corresponds to \( B = U \cdot D \cdot V^T \) where (i) \( D \in \mathbb{R}^{r \times r} \) is a diagonal matrix with nonzero entries and (ii) the columns of \( U \) and \( V \) are orthonormal. The columns of \( U \) form an orthonormal basis for the column span of \( B \). Similarly, the columns of \( V \) form an orthonormal basis for the row span of \( B \).

We will also need the following random sampling result concerning rank one matrices due to Rudelson and Vershynin [35].

**Theorem 2.12.** Let \( Z \) be a distribution over \( \mathbb{R}^n \) such that with probability 1, for \( Z \sim Z \), we have \( \|Z\|_2 \leq M \). Assume that \( \|\mathbb{E}[Z \otimes Z]\|_2 \leq 1 \). Let \( Z_1, \ldots, Z_d \) be i.i.d. copies of \( Z \). Let \( a \) be defined as

\[
a = C \sqrt{\frac{\log d}{d M}},
\]

for an absolute constant \( C > 0 \). Then,

\[
\Pr \left[ \left\| \frac{1}{d} \cdot (\sum_{j=1}^d Z_j \otimes Z_j) - \mathbb{E}[Z \otimes Z] \right\|_2 > t \right] \leq 2e^{-Ct^2/a^2}.
\]

Next, we recall the notion of pseudoinverse of a matrix [27, 32]. Our definition below is specialized to real square matrices though the definition can be generalized to complex rectangular matrices as well.

**Definition 2.13.** For any square matrix \( A \in \mathbb{R}^{n \times n} \), there is a unique matrix \( B \) which satisfies the following conditions (known as the Moore-Penrose conditions):

1. \( ABA = A \) and \( BAB = B \).
2. \((AB)^\dagger = AB \) and \((BA)^\dagger = BA \).

B is referred to as the pseudoinverse of \( A \). We remark that when \( A \) is invertible, then \( B = A^{-1} \). We will thus overload this notation and in general, use \( A^{-1} \) to denote the pseudoinverse of \( A \).

**Claim 2.14.** Let \( A \in \mathbb{R}^{m \times m} \) be a symmetric matrix whose non-zero eigenvalues are \( \{\lambda_1, \ldots, \lambda_t\} \) and corresponding orthonormal vectors \( \{v_1, \ldots, v_t\} \) (note that \( t \leq m \)). Then,

\[
A = \sum_{i=1}^t \lambda_i v_i v_i^T \quad \text{and} \quad A^{-1} = \sum_{i=1}^t \frac{1}{\lambda_i} v_i v_i^T.
\]

**Proof.** It is immediate to verify that the Moore-Penrose conditions from Definition 2.13 hold for \( A^{-1} \) defined as above (uses the fact that \( v_i \) are orthonormal). \( \square \)

**Definition 2.15.** For a symmetric matrix \( A \in \mathbb{R}^{n \times n} \) and a parameter \( \eta \in \mathbb{R} \), we define \( A_{\geq \eta} \in \mathbb{R}^{n \times n} \) as projection of \( A \) to the eigenspaces with eigenvalue more than \( \eta \). In other words, let the spectral decomposition of \( A \) be

\[
A = \sum_{i=1}^n \lambda_i v_i v_i^T.
\]

Then,

\[
A_{\geq \eta} = \sum_{i: \lambda_i \geq \eta} \lambda_i v_i v_i^T.
\]

Further, for \( \eta > 0 \), we define \( A_{\geq \eta}^{-1} \) is defined to be

\[
A_{\geq \eta}^{-1} = \sum_{i: \lambda_i \geq \eta} \frac{1}{\lambda_i} v_i v_i^T.
\]

Note that this is the same as the pseudoinverse of \( A_{\geq \eta} \). Finally, for a symmetric matrix \( A \) and parameter \( \eta \in \mathbb{R} \), we let \( \mathbb{E}_\eta(A) \) denote span(\( \{v_i\}_{\lambda_i \geq \eta} \)).
2.3 Algorithmic ingredients

We will require some algorithmic ingredients from the paper [15]. The first is Lemma 10 in the full version from [15] which is stated below.

**Lemma 2.16.** There is an algorithm Compute-inner-product which given oracle access to function \( g : \mathbb{R}^n \to [-1, 1] \), noise parameter \( t > 0 \), error parameter \( \epsilon > 0 \), confidence parameter \( \delta > 0 \) and has the following guarantee:

1. It makes \( \text{poly}(t, 1/\epsilon, \log(1/\delta)) \) queries to \( g \).
2. With confidence \( 1 - \delta \), it outputs \( \langle \nabla(P_t g)(y_1), \nabla(P_t g)(y_2) \rangle \) up to additive error \( \pm \epsilon \).

The second lemma we need appears as Lemma 12 in the full version of [15] and is stated below.

**Lemma 2.17.** There is an algorithm Project-on-gradient which given oracle access to function \( g : \mathbb{R}^n \to [-1, 1] \), noise parameter \( t > 0 \), error parameters \( \eta, \nu > 0 \) and confidence parameter \( \delta > 0 \), has the following guarantee: For any \( x, y \in \mathbb{R}^n \), there is a quantity \( \text{Est}(x, y) \) which satisfies

\[
\Pr_{y \sim \gamma_n} \left[ |\text{Est}(x, y) - \langle \nabla P_t g(x), y \rangle| > \lambda \eta \right] \leq \frac{1}{\lambda^2}.
\]

The algorithm Project-on-gradient with probability \( 1 - \delta \), outputs an \( \pm \nu \)-additive estimate of \( \text{Est}(x, y) \) and makes \( \text{poly}(1/t, 1/\eta, 1/\nu, \log(1/\delta)) \) queries to \( g \).

3 Projection on low-dimensional space and correlation with linear juntas

The goal of this section is to prove the following theorem.

**Theorem 3.1.** Let \( h : \mathbb{R}^n \to [-1, 1] \) be a \( C \)-Lipschitz function and \( \eta, \delta > 0 \). Let \( x_1, \ldots, x_M \sim \gamma_n \) where \( M \geq \frac{C^2}{\eta^2} \log(\frac{C}{\delta}) \). Then, with probability \( 1 - \delta \), the matrix \( A \in \mathbb{R}^{n \times n} \) defined as

\[
A = \frac{1}{M} \sum_{j=1}^{M} \nabla h(x_j) \cdot \nabla h(x_j)^T,
\]

satisfies the following: Let \( E = E_{\eta/2}(A) \) and let \( s \geq 0 \). Then,

\[
\rho_{E, k, s}(h) \geq \rho_{E_{\eta/2}, k, s}(h) - \sqrt{k \cdot \eta}.
\]

At a high level, this theorem says that for any Lipschitz function \( h \), its correlation with the best linear \( k \)-junta essentially remains preserved if we restrict our attention to the subspace obtained by spectrally truncating the empirical covariance matrix of \( \nabla h \). It is the first step in realizing part I. from Section 1.4 (the other step is to handle the fact that we can only estimate \( A \)).

The proof of Theorem 3.1 follows from the following lemma.

**Lemma 3.2.** Let \( E \) be a subspace of \( \mathbb{R}^n \) and let \( f : \mathbb{R}^n \to \mathbb{R} \) be such that for every unit vector \( v \in E^{\perp} \), \( \mathbb{E}[\langle v, \nabla f(x) \rangle^2] \leq \delta \). Then, for any \( s > 0 \),

\[
\max_{g \in J_{E, k, s}} \mathbb{E}_x[ f(x) \cdot g(x) ] \geq \max_{h \in J_{E_{\eta/2}, k, s}} \mathbb{E}_x[ f(x) \cdot h(x) ] - \sqrt{k \cdot \eta}.
\]
Proof of Theorem 3.1: Define the matrix $A_{avg}$ as
\[ A_{avg} = E_x[\nabla h(x) \cdot \nabla h(x)'] \]
Observe that by Theorem 2.12 with probability $1 - \delta$, we have that $\|A_{avg} - A\| \leq \eta/2$. This implies that for any unit vector $v \in E^\perp$, we have
\[ E_x[(v, \nabla h(x))^2] = v^T \cdot A_{avg} \cdot v \leq v^T \cdot A \cdot v + \frac{\eta}{2} \leq \eta. \] (2)
Then, applying Lemma 3.2 to the function $h$ and the subspace $E$, we have the proof. \(\square\)
We now turn to proving Lemma 3.2.

Proof of Lemma 3.2: Choose any $h \in \mathcal{F}_{E';k,s}$ and let $h \in \mathcal{F}_F$ for some subspace $F$ with $\dim(F) \leq k$. Let $E' = \text{span}(E \cup F)$ and define $g = \mathcal{A}_h$. Observe that $g$ is $s$-smooth (by Item 2 of Proposition 2) and thus $g \in \mathcal{F}_{E;h}$. Also, observe that $h = \mathcal{A}_E h$. We now have
\[
\left| E_x[f(x) \cdot g(x)] - E_x[f(x) \cdot h(x)] \right| = \left| E_x[f(x) \cdot \mathcal{A}_E h(x)] - E_x[f(x) \cdot \mathcal{A}_E f(x)] \right|
\]
\[
= \left| E_x[\mathcal{A}_E f(x) \cdot h(x)] - E_x[\mathcal{A}_E f(x) \cdot h(x)] \right| \text{ (Item 5 of Lemma 2.2)}
\]
\[
\leq \left( E_x[(\mathcal{A}_E f(x) - \mathcal{A}_E f(x))^2] \right)^{\frac{1}{2}} \text{ (by Cauchy-Schwarz).} \] (3)
We now seek to bound the right hand side of (3). Towards this, let us split $\mathbb{R}^n = E' \oplus H$ and $E' = E \oplus J$. Here $H$ is the orthogonal complement of $E'$ and $J$ is the orthogonal complement of $E$ inside $E'$. For any $x \in \mathbb{R}^n$, we express it as $(x_H, x_J, x_E)$ ($x_E$ represents the component of $x$ along the subspace $J$ and likewise for $H$ and $E$). Observe that for $x = (x_H, x_J, x_E)$, we have
\[ \mathcal{A}_E f(x) = E_{x_H}[f(x_H', x_J, x_E)] \text{ and } \mathcal{A}_E f(x) = E_{x_H}[f(x_H', x_J', x_E)]. \] (4)
Thus, we now have the following:
\[
E_x[(\mathcal{A}_E f(x) - \mathcal{A}_E f(x))^2] = E_{x_H,x_J,x_E}(E_{x_H'}[f(x_H', x_J, x_E)] - E_{x_H'}[f(x_H', x_J', x_E)])^2
\]
\[
= E_{x_H,x_E}(E_{x_H'}[f(x_H', x_J, x_E)] - E_{x_H'}[f(x_H', x_J', x_E)])^2
\]
\[
\leq E_{x_H,x_J,x_E}((f(x_H, x_J, x_E) - E_{x_J'}[f(x_H', x_J', x_E)])^2). \] (5)
The last inequality follows from Jensen’s inequality. Next, for any $x = (x_J, x_H, x_E)$, define $f_{x_H,x_E}: \mathbb{R}^J \to \mathbb{R}$ as $f_{x_H,x_E}(x_J) = f(x_H, x_J, x_E)$. Then,
\[ \Pi_J \nabla f(x) = \nabla f_{x_H,x_E}. \] (6)
Now applying the definition of $f_{x_H,x_E}$ to (5) and subsequently applying the Gaussian Poincaré inequality, we get
\[
E_x[(\mathcal{A}_E f(x) - \mathcal{A}_E f(x))^2] \leq E_{x_H,x_J,x_E}((f_{x_H,x_E}(x_J) - E_{x_J'}[f_{x_H,x_E}(x_J')])^2)
\]
\[
\leq E_{x_H,x_J,x_E}[(\nabla f_{x_H,x_E}(x_H, x_J, x_E))^2]. \]
Finally, applying (6), we get
\[
E_x[(\mathcal{A}_E f(x) - \mathcal{A}_E f(x))^2] \leq E_{x_H,x_J,x_E}[(\Pi_J \nabla f(x_H, x_J, x_E))^2].
\]
Now, by our assumption, for any direction $v$ in $J$ (since it is orthogonal to $E$), $E_{x}[(\Pi_J \nabla f(x))^2] \leq \delta$. Since the dimension of $J$ is at most $k$, we get that
\[
E_x[(\mathcal{A}_E f(x) - \mathcal{A}_E f(x))^2] \leq k\delta.
\]
Combining with (3), we get the claim. \(\square\)
4 Roadmap for proving Theorem 1.2 and Theorem 1.3

In this section, we prove Theorem 1.2 and Theorem 1.3. In fact, Theorem 1.2 is a simple corollary of Theorem 1.3 which we describe now. Subsequently, we prove Theorem 1.3.

Proof of Theorem 1.2. The proof follows from the following simple observations.

1. Suppose there is a linear-k-junta \( g \) with surface area at most \( s \) and \( \text{dist}(f, g) \leq c_\ell \). Observe that \( g \) is \( s' \)-smooth (Item 1 from Proposition 2.8) where \( s' = 2s/\sqrt{\ell} \). Further, its correlation with \( g \) is at least \( 1 - 2c_\ell \).

2. On the other hand, also observe that for any \( f : \mathbb{R}^n \to \{-1, 1\} \), the closest linear-k junta \( g : \mathbb{R}^n \to [-1, 1] \) is \( \{\pm 1\} \) valued.

Using the above observations, we infer the following. For this, define \( \Delta = (c_u + c_\ell)/2 \).

(a) If \( f \) is \( c_\ell \)-close to some linear \( k \)-junta \( g : \mathbb{R}^n \to \{-1, 1\} \) with surface area at most \( s \), then \( \rho_{\mathbb{R}^n,k,s} \geq 1 - 2c_\ell \).

(b) If \( f \) is \( c_u \)-far from every linear \( k \)-junta \( g : \mathbb{R}^n \to \{-1, 1\} \), then \( \rho_{\mathbb{R}^n,k,s} \leq 1 - 2c_u \).

Thus, if we call Correlation-smooth-junta on the function \( f \) with error parameter \( \epsilon = (c_u - c_\ell)/4 \), then the output \( \hat{\rho}_{\mathbb{R}^n,k,s} > \Delta \) if \( f \) is in case (a). Likewise, if the output \( \hat{\rho}_{\mathbb{R}^n,k,s} \leq \Delta \), if \( f \) is in case (b). This finishes the proof. \( \square \)

We now turn to the proof of Theorem 1.3. Our first step is to replace the function \( f \) by a smoothed version:

Lemma 4.1. For smoothness parameter \( s \), error parameter \( \kappa > 0 \) and \( f : \mathbb{R}^n \to [-1, 1] \), the function \( f_{\text{sm}} = P_{s/1} f \) has the following guarantees:

1. \( f \in C^\infty \) and \( f \) is \( L \)-Lipschitz for \( L = O(s^2/\kappa^2) \).

2. For any \( x \in \mathbb{R}^n \), \( f_{\text{sm}}(x) \) can be computed to error \( \eta/10 \) with probability \( 1 - \delta \) using \( T(\eta, \delta) = \text{poly}(1/\eta, \log(1/\delta)) \) queries to the oracle for \( f : \mathbb{R}^n \to [-1, 1] \).

3. Finally,

\[
\left| \rho_{\mathbb{R}^n,k,s}(f_{\text{sm}}) - \rho_{\mathbb{R}^n,k,s}(f) \right| \leq \frac{\kappa}{2}.
\]

Proof. The first property follows from Fact 2.5 and the definition of the noise operator \( P_t \). The second property follows easily from the definition of \( P_{s/1} \). We simply have to take enough samples to estimate the expectation. Finally, suppose \( g \) is an \( s \)-smooth linear \( k \)-junta such that

\[
\mathbb{E}[f(x) \cdot g(x)] = \rho_{\mathbb{R}^n,k,s}(f).
\]

As \( g \) is \( s \)-smooth, it follows that \( \mathbb{E}[|P_{s/1} g(x) - g(x)|] = O(\kappa) \). This in turn implies that

\[
\mathbb{E}[f_{\text{sm}}(x) \cdot g(x)] = \mathbb{E}[f(x) \cdot P_{s/1} g(x)] \geq \rho_{\mathbb{R}^n,k,s}(f) - O(\kappa).
\]

Using Lemma 4.1, it suffices to prove Theorem 1.3 for Lipschitz functions. In particular, we shall prove the following version of Theorem 1.3 for Lipschitz functions.

Theorem 4.2. There is an algorithm Correlation-smooth-junta with the following guarantee: Let \( f_{\text{sm}} : \mathbb{R}^n \to [-1, 1] \) be an infinitely differentiable \( L \)-Lipschitz function such that \( f_{\text{sm}} = P_u f \) for a parameter \( u > 0 \) (where \( f : \mathbb{R}^n \to [-1, 1] \)). The algorithm is given oracle access to the functions \( f_{\text{sm}} \) and \( f \). It also gets as inputs, error parameter \( \epsilon > 0 \), junta arity parameter \( k \) and outputs an estimate \( \hat{\rho}_{\mathbb{R}^n,k,s}(f) \) (with probability at least \( 2/3 \)) with the following guarantee:

\[
|\hat{\rho}_{\mathbb{R}^n,k,s}(f_{\text{sm}}) - \rho_{\mathbb{R}^n,k,s}(f_{\text{sm}})| \leq \epsilon.
\]
Here $\rho_{\mathbb{R}^n,k,s}(f_{sm})$ is the maximum correlation of $f_{sm}$ with any $s$-smooth $k$-linear junta. The query complexity of the algorithm is $\text{poly}(L/u) \cdot k^{O(s^2/\epsilon^2)}$.

Further, the algorithm also works even when we have a noisy oracle to $f_{sm}$ – in particular, the above guarantee holds even when each evaluation of $f_{sm}(\cdot)$ at $x$ returns $\pm \eta$ additive error estimate for $\eta = \text{poly}(u/L) \cdot k^{O(s^2/\epsilon^2)}$.

To obtain Theorem 1.3 we let $\kappa = \epsilon/4$, $u = \kappa/s$. Define $f_{sm} = P_u f$. We now invoke Theorem 4.2 on $f_{sm}$ with error parameter $\epsilon/2$ – observe that the output $\hat{\rho}_{\mathbb{R}^n,k,s}(f_{sm})$ satisfies

$$|\hat{\rho}_{\mathbb{R}^n,k,s}(f_{sm}) - \rho_{\mathbb{R}^n,k,s}(f)| < \epsilon.$$  

Finally, observe that while we do not have oracle access to $f_{sm}$, Theorem 4.2 only requires to evaluate $f_{sm}(\cdot)$ with an additive error of $\pm \eta = \text{poly}(u/L) \cdot k^{O(s^2/\epsilon^2)}$. Observe that the number of queries made by Theorem 4.2 is $Q = \text{poly}(L/u) \cdot k^{O(s^2/\epsilon^2)}$. Set $\delta = 1/(10Q)$. Using Lemma 4.1 we can evaluate $f_{sm}(x)$ by making $\eta^{-2} \log(1/\delta)$ to the oracle for $f$. For our choice of $\delta$, this means that with probability $9/10$, all our evaluations of $f_{sm}(\cdot)$ are $\pm \eta$ accurate. This means that we can simulate our queries to $f_{sm}$ by using the oracle for $f$ with a multiplicative overhead of $\eta^{-2} \log(1/\delta)$. Plugging in the values of $\eta$ and $\delta$, we get the final claim.

## 5 Proof of Theorem 4.2

We now turn to the proof of Theorem 4.2. For the moment, we will just assume that we can evaluate $f_{sm}$ at any point $x$ exactly. From the description of our algorithm, it would be clear that the guarantee of algorithm continues to hold even if each evaluation of $f_{sm}(x)$ has an additive error of $\pm \eta = \text{poly}(u/L) \cdot k^{O(s^2/\epsilon^2)}$. We will bring this to attention of the reader at the relevant points. The algorithm Correlation-smooth-junta invokes two crucial subroutines. The first is the routine Implicit projection described in Figure 1.

### 5.1 Implicit projection algorithm

**Lemma 5.1.** The algorithm Implicit projection takes as input oracle access to $f : \mathbb{R}^n \to [-1,1]$ and $f_{sm} : \mathbb{R}^n \to [-1,1]$, parameters $u, L > 0$, error parameter $\nu > 0$ and junta arity parameter $k$. Suppose $f_{sm} = P_u f$. The algorithm makes poly($1/u, 1/\nu, L$) queries to $f$ and $f_{sm}$ and with probability $9/10$, has the following guarantee: For $M = \text{poly}(k/\nu)$, it outputs $M$ points $x_1, \ldots, x_M$ and a matrix $W \in \mathbb{R}^{M \times M}$. Let $B^T \in \mathbb{R}^{M \times n}$ be the matrix whose $j$th row is $\nabla f_{sm}(x_j)$ and $\hat{E}$ be the span of the rows of $\hat{W}B^T$. Then,

$$\rho_{E,k,s}(f_{sm}) \geq \rho_{\mathbb{R}^n,k,s}(f_{sm}) - \frac{\nu}{2}.$$  

Further, the matrix $\hat{W}$ satisfies

$$\|\Pi_{\hat{E}} - B\hat{W}^T\hat{W}B^T\|_F = \|\hat{I} - \hat{W}B^T\hat{W}B^T\|_F \leq \nu/2,$$  

where $\hat{I}$ denotes the identity matrix in $M$ dimensions. Finally, the matrix $\hat{W}$ satisfies $\|\hat{W}\|_2 \leq 20k/\nu$.

The high level idea of the lemma is the following: Let $E$ denote the subspace spanned by the rows of $B^T$. Let us define $N = B^T \hat{E}$ and $\hat{\Pi} = B\hat{W}^T\hat{W}B^T$. To understand the high level idea behind the algorithm Implicit projection, observe that if in Step 2, we could compute $\langle \nabla f_{sm}(x), \nabla f_{sm}(x_j) \rangle$ exactly, then $\hat{N} = N$. Consequently, if $\eta > 0$ is sufficiently small, then it is easy to see that the rows of $\hat{W}B^T$ form an orthonormal basis of $E$ and consequently, $\hat{\Pi}$ is a projection matrix into $E$. Unfortunately for us, we will not have access to $B$ explicitly and thus are only able to compute an approximation to $N$, namely $\hat{N}$. The goal here is two-fold: (a) Understand why the rows of $\hat{W}B^T$ are essentially orthonormal; (b) $\rho_{E,k,s}(f)$ is close to $\rho_{E,k,s}(f)$.

The next claim quantifies the sense in which the rows of $\hat{W}B^T$ are almost orthonormal.
**Lemma 5.2.** For matrices  and  ,  and  (as described in the algorithm Implicit projection), let . (That is,  has a 1 corresponding to large eigenvalues of  .) Let be the span of the rows of . Then

\[
\|\Pi_{\hat{E}} - B\hat{W}^T\hat{W}B^T\|_F = \|\hat{I} - \hat{W}B^T\cdot B\hat{W}^T\|_F \leq \frac{4}{\eta}\|\hat{N} - B^T B\|_F.
\]

**Proof.** Since  , we can write

\[
\hat{I} = (\hat{D}_{\sqrt{\eta/2}})^{-1}\hat{V}^T\hat{N}\hat{V}(\hat{D}_{\sqrt{\eta/2}})^{-1}.
\]

Then

\[
\hat{I} - \hat{W}B^T\hat{W}^T = (\hat{D}_{\sqrt{\eta/2}})^{-1}\hat{V}^T(\hat{N} - B^T B)\hat{V}(\hat{D}_{\sqrt{\eta/2}})^{-1}.
\]

Finally, note that \(\|(\hat{D}_{\sqrt{\eta/2}})^{-1}\| \leq \frac{2}{\sqrt{\eta}}\) and \(\|AB\|_F \leq \|A\|_F \|B\|\) for any matrices  and  . This proves the claimed inequality. To see the equality, note that  and  have the same eigenvalues, and both expressions can be expressed as \((\sum_{i}(\lambda_i - 1)^2)^{1/2},\) where the sum ranges over non-zero eigenvalues.

Having shown that the rows of  are close to being orthonormal, we next show that the rows of  essentially span  – more precisely, we show that \(\Pi_{E^y(BB^T)}(I - B\hat{W}^T\hat{W}B^T)\) is small.

---

**Implicit projection algorithm**

1. Sample  random points  , ...,  where  .
2. For each  , with confidence parameter  and error parameter  , we compute  using algorithm Compute-inner-product from Lemma 2.16. Denote this by  and let as the corresponding symmetric matrix.
3. Let be the closest psd matrix to  in Frobenius norm (can be computed using convex programming).
4. Let  be the spectral decomposition of  .
5. Output the points  and the matrix  .

---

Figure 1: Description of the testing algorithm Implicit projection
Lemma 5.3. For matrices $\hat{D}$, $\hat{W}$, $B$, $\hat{N}$ and $\eta > 0$ (as described in the algorithm Implicit projection),

\[
\|\Pi_{E_{\infty}(BB^T)}(I - B\hat{W}^T\hat{W}B^T)\| \leq \frac{20\|B^TB\|_F \cdot \|B^TB\|}{\eta^2} \sqrt{\|\hat{N} - B^TB\|}.
\]

Proof. Recall that $B = UDV^T$ is a singular value decomposition of $B$. Let $U \geq \sigma$ consist of the rows of $U$ whose singular values are at least $\sqrt{\eta}$, so that

\[
\Pi_{E_{\infty}(BB^T)} = U \geq \sqrt{\eta}U^T = U_\geq \sqrt{\eta}U^T.
\]  

(9)

\[
\|\Pi_{E_{\infty}(BB^T)}(I - B\hat{W}^T\hat{W}B^T)\| = \|\Pi_{E_{\infty}(BB^T)}(I - B(\hat{N}_{\infty}/4)^{-1}B^T)\|
\]

\[
= \|U_\geq \sqrt{\eta}U^T - U_\geq \sqrt{\eta}DV^T(\hat{N}_{\infty}/4)^{-1}VDU^T\|
\]

\[
= \|V_\geq \sqrt{\eta}V^T - V_\geq \sqrt{\eta}DV^T(\hat{N}_{\infty}/4)^{-1}VDU^T\|
\]

\[
= \|V_\geq \sqrt{\eta}V^T - (N_{\infty})^{1/2}(\hat{N}_{\infty}/4)^{-1}N^{1/2}\|
\]

where in the last line we set $N = B^TB$. The first equality uses $\hat{W}^T\hat{W} = (\hat{N}_{\infty}/4)^{-1}$. The second and third equality uses that $\|A\| = \|\Lambda A^T\|$ for unitary matrix $\Lambda$ and the last equality sets $N = VDV^T$. Now, observe that $V_\geq \sqrt{\eta}V^T = (N_{\infty})^{1/2}(N_{\infty}/4)^{-1}N^{1/2}$. we have

\[
\|\Pi_{E_{\infty}(BB^T)}(I - B\hat{W}^T\hat{W}B^T)\| = \|(N_{\infty})^{1/2}(N_{\infty}/4)^{-1}N^{1/2}\|
\]

\[
\leq \|N\| \cdot \|\Pi_{E_{\infty}(N)}((N_{\infty}/4)^{-1} - (\hat{N}_{\infty}/4)^{-1})\|
\]

(10)

Finally, we apply Lemma B.3 to get that

\[
\|\Pi_{E_{\infty}(N)}((N_{\infty}/4)^{-1} - (\hat{N}_{\infty}/4)^{-1})\| \leq \frac{20\|N\|_F \sqrt{\|N - \hat{N}\|}}{\eta^{5/2}}.
\]

Combining this with (11), we get the result. \qed

Lemma 5.4. If $f_{sm} : \mathbb{R}^n \to [-1, 1]$ is $L$-Lipschitz then with probability $1 - \delta$,

\[
\rho_{E,k,s}(f_{sm}) \geq \rho_{E,k,s}(f_{sm}) - \sqrt{k \cdot \eta} - \frac{80L^4 \cdot M^{5/2}}{\eta^{5/2}} \sqrt{\|\hat{N} - B^TB\|} - \frac{16L}{\eta} \|\hat{N} - B^TB\|_F.
\]

Here $\delta$ is as instantiated in Algorithm Implicit projection.

Proof. Define $E = E_{\infty/2}(BB^T)$. Let $\hat{E}$ be the span of the rows of $\hat{W}B^T$. Then

\[
\|\Pi_E \Pi_{\hat{E}}\| = \|\Pi_E - \Pi_E \hat{E} + \Pi_E(\hat{E} - \Pi_{\hat{E}})\|
\]

\[
\leq \|\Pi_E - \Pi_E \hat{E}\| + \|\hat{E} - \Pi_{\hat{E}}\| + \frac{4\|\hat{N} - B^TB\|_F}{\eta} \sqrt{\|\hat{N} - B^TB\|} + \frac{4\|\hat{N} - B^TB\|}{\eta} \|\hat{N} - B^TB\|_F
\]

(11)

where the last line follows from Lemmas 5.3 and 5.2. We now apply Corollary A.4 to the above to get

\[
\rho_{E,k,s}(f_{sm}) \geq \rho_{E,k,s}(f_{sm}) - 4L\|\Pi_E(\Pi_{E'}^\perp)\|_F
\]

\[
\geq \rho_{E,k,s}(f_{sm}) - \frac{80L \cdot \sqrt{M}}{\eta^{5/2}} \|B^TB\|_F \|B^TB\| \sqrt{\|\hat{N} - B^TB\|} - \frac{16L}{\eta} \|\hat{N} - B^TB\|_F
\]

(12)
On the other hand, using Theorem 5.1 with probability $1 - \delta$, we also have

$$\rho_{E,k,s}(f_{\text{sm}}) \geq \rho_{E,\infty,k,s}(f_{\text{sm}}) - \sqrt{k} \cdot \eta.$$  

Combining the above with (12), we get that with probability $1 - \delta$,

$$\rho_{E,k,s}(f_{\text{sm}}) \geq \rho_{E,\infty,k,s}(f_{\text{sm}}) - \sqrt{k} \cdot \eta - \frac{80L \cdot \sqrt{M}}{\eta^{5/2}} \|B^T B\|_F \|B^T B\|_F \sqrt{||N - B^T B||} - \frac{16L}{\eta} ||N - B^T B||_F. \quad (13)$$

Now, observe that $||B^T B||_F \leq ML^2$ (Since $f_{\text{sm}}$ is $L$-Lipschitz, each row has norm at most $L$). This then implies that

$$\rho_{E,k,s}(f_{\text{sm}}) \geq \rho_{E,\infty,k,s}(f_{\text{sm}}) - \sqrt{k} \cdot \eta - \frac{80L^4 \cdot M^{5/2}}{\eta^{5/2}} \sqrt{||N - B^T B||} - \frac{16L}{\eta} ||N - B^T B||_F.$$

Proof of Lemma 5.1. By our setting of parameters, observe that with probability $1 - \delta$, the matrix $\hat{A}$ satisfies $||\hat{A} - B^T B||_{\infty} \leq \epsilon'$. This in turn implies that $||\hat{A} - B^T B||_F \leq \epsilon' \cdot M$. Since $\hat{N}$ is the closest psd matrix to $\hat{A}$, this means $||N - \hat{N}||_F \leq 2\epsilon \cdot M$

Plugging the values of $\epsilon'$, $\eta$ and $M$ into Lemma 5.4 shows that $\rho_{E,k,s}(f_{\text{sm}})$ satisfies (7) with probability $1 - 2\delta = 9/10$. Similarly, (8) follows by plugging the values of $\epsilon'$, $\eta$ and $M$ into Claim 5.2. Finally, observe that the query complexity of the algorithm is dictated by Step 2 (i.e., the query complexity of the routine Compute-inner-product). By plugging in Lemma 2.16, we get that the query complexity is $\text{poly}(M, 1/\mu, 1/\epsilon')$. Plugging in the values of these parameters (from the description of the algorithm Implicit projection), we get the claim.

Finally, to get an upper bound on $||\hat{W}||_2$, observe that $\hat{W} = \hat{D} \cdot \sqrt{\eta/2} \cdot \hat{V}$. This means that $||\hat{W}||_2 \leq 2/ \sqrt{\eta}$. Plugging in the value of $\eta$ from the description of Implicit projection, we get the claim. ☐

5.2 Hypothesis testing on low-dimensional space

Our final technical task is to show that functions on a low-dimensional space can be adequately “pulled back” to $\mathbb{R}^n$ under an approximate projection. The first observation is that an approximate projection can be approximated by a projection:

Lemma 5.5. For any $m \leq n$ and any $m \times n$ matrix $X$ of rank $m$, there exists an $m \times n$ matrix $Y$ with orthogonal rows, such that

$$||X - Y||_F \leq ||XX^T - I||_F.$$  

Proof. Let $UD^2U^T = XX^T$ be a singular value decomposition of $XX^T$. Then $I = (D^{-1}U^T X)(D^{-1}U^T X)^T$, and it follows that $V^T := D^{-1}U^T X$ is an orthogonal matrix. Let $Y = UV^T$. Noting that $X = UD^2U^T$, we have $||X - Y||_F^2 = ||D - I||_F^2$, and if $\sigma_1, \ldots, \sigma_m$ are the singular values of $X$ then

$$||D - I||_F^2 = \sum (\sigma_i - 1)^2 \leq \sum (\sigma_i^2 - 1)^2 = ||XX^T - I||_F^2.$$  

☐

5.2.1 The existence of a small net  
We now prove the existence of a small net of Lipschitz functions for the family of $s$-smooth $k$-linear Juntas in $\mathbb{R}^n$. The main result is Proposition 5.11.

We begin with a few preliminaries related to approximate by Lipschitz functions, namely, $s$-smooth functions can be approximated by Lipschitz functions and Lipschitz functions don’t change much under composition by nearby linear maps.

Lemma 5.6. For every $s$-smooth function $f : \mathbb{R}^n \rightarrow [-1, 1]$ and every $\epsilon > 0$, there is a $C_s/\epsilon$-Lipschitz function $g : \mathbb{R}^n \rightarrow [-1, 1]$ such that $||f - g||_{L^2(\gamma)} \leq \epsilon$. Here $C_s$ is the absolute constant appearing in Fact 2.5.
Proof. Choose $t = \frac{e^2}{\varepsilon^2}$ and set $g = P_t f$, so that the bound $\|f - g\|_{L^2(\gamma)} \leq \varepsilon$ follows from the fact that $f$ is $s$-smooth. The claim follows from Fact 2.5. \hfill \square

Lemma 5.7. Suppose that $g : \mathbb{R}^m \rightarrow \mathbb{R}$ is Lipschitz and let $X$ and $Y$ be two $m \times n$ matrices. Then $\|g \circ X - g \circ Y\|_{L^2(\gamma)} \leq (\text{Lip } g)\|X - Y\|_F$ (here Lip $g$ denotes the Lipschitz constant of $g$).

Proof. Let $x$ be a standard normal random variable on $\mathbb{R}^n$. Then
\[
\mathbf{E}[(g \circ X)(x) - (g \circ Y)(x)]^2 \leq (\text{Lip } g)^2 \mathbf{E}[\|Xx - Yx\|^2] = (\text{Lip } g)^2\|X - Y\|^2_F.
\]
\hfill \square

Our procedure for producing a net for $s$-smooth $k$-juntas in $\mathbb{R}^m$ proceeds in three steps. First, we will construct a net for $s$-smooth functions on $\mathbb{R}^k$. Then we will find a net for $k$-dimensional subspaces of $\mathbb{R}^m$. Combining these two nets will give a net for $s$-smooth $k$-juntas in $\mathbb{R}^m$.

We begin with the net for $s$-smooth functions on $\mathbb{R}^k$. Before we do, we recall the following simple fact.

Fact 5.8. For the unit sphere in $\mathbb{R}^m$ (denoted by $S^{m-1}$), there is a $\delta$-net (in Euclidean sphere) of size $(1/\delta)^{O(m)}$.

Lemma 5.9. For any $k \in \mathbb{N}$ and any $s, \varepsilon > 0$, there exists a set \text{Net} of functions $\mathbb{R}^k \rightarrow [-1,1]$ such that

1. every function in \text{Net} is $\frac{s^2}{\varepsilon}$-Lipschitz (here $C$ is the absolute constant appearing in Fact 2.5).
2. \text{Net} is an $\varepsilon$-net for the set of $s$-smooth functions $\mathbb{R}^k \rightarrow [-1,1].$
3. $\log |\text{Net}| \leq k^{O(s^2/\varepsilon^2)},$ and
4. Every function $f$ in \text{Net} is $s$-smooth.

Proof. We first construct a set \text{Net} which satisfies properties (2), (3) and (4) (in fact, the functions in \text{Net} will be $s$-smooth). Once we achieve this, for every $g \in \text{Net}$, we will include $P_{sg}$ in \text{Net} and discard $g$. Observe that since $g$ is $s$-smooth, for $u = \varepsilon^2/s^2$, $P_{sg}/\sqrt{u} = O(s/\varepsilon)$-Lipschitz. Further, observe that the property of being $s$-smooth is closed under the noise operator $P_s$. Thus, properties (1)-(4) are then simultaneously satisfied.

We now turn to construction of \text{Net} satisfying (2) and (3) such that every function in \text{Net} is $s$-smooth. To do this, we assume that the reader is familiar with the basics of Hermite analysis (see Chapter 11 of [29]). In particular, recall that the Hermite polynomials over $\mathbb{R}^k$ are indexed by $S \in (\mathbb{N}^*)^k$ (where $\mathbb{N}^* = \mathbb{N} \cup \{0\}$). Further, every $f \in L_2(\gamma_k)$ can be represented as
\[
f(x) = \sum_{S \in (\mathbb{N}^*)^k} \hat{f}(S)H_S(x) \quad \text{and} \quad P_{sf}(x) = \sum_{S \in (\mathbb{N}^*)^k} \hat{f}(S)e^{-r||S||_1}H_S(x).
\]

Let $\delta > 0$ which we will fix later. Set $t = \delta^2/s^2$.
\[
\sum_{S} \hat{f}^2(S)(1 - e^{-r||S||_1}) = \mathbf{E}_x[|f(x) - P_{sf}(x)|] \leq \mathbf{E}_x[||f(x) - P_{sf}(x)||] \leq \delta.
\]

Here the equality follows from Parseval’s identity, the first inequality uses the fact that the range of $f$ is $[-1,1]$ and the second inequality uses the assumption that $f$ is $s$-smooth.

Set $m = 1/t$ and this means that $\sum_{||S||_1 \geq m} \hat{f}^2(S) \cdot (1 - \frac{1}{e}) \leq \delta$. Consequently, we have
\[
\sum_{||S||_1 \geq m} \hat{f}^2(S) \leq \delta \cdot \frac{e}{e - 1} < 4\delta.
\]

Let us define $f_{tr} = \sum_{||S||_1 \leq m} \hat{f}(S)H_S(x)$. This means that for $f_{tr} : \mathbb{R}^k \rightarrow \mathbb{R}$, $\|f_{tr} - f\|^2_{L_2(\gamma)} < 4\delta$. Next, we recall that the unit ball in $\ell_2^M$ admits a $\delta$-net of size $(1/\delta)^{O(M)}$ (Fact 5.8). Since the cardinality of the set $\{S : ||S||_1 \leq m\}$ is at most $k^m$, we get that there is a set of functions \text{Net}_{fr} with the following properties:
1. Every \( g \in \text{Net}_{tr} \) satisfies \( g : \mathbb{R}^k \rightarrow \mathbb{R} \) and \( |\text{Net}_{tr}| \leq (1/\delta)^{O(km)} \).

2. There exists some \( g \in \text{Net}_{tr} \) such that \( \mathbb{E}_x[(g(x) - f(x))^2] \leq \delta \). This implies that \( \mathbb{E}_x[(g(x) - f(x))^2] \leq 10\delta \).

Finally, we set \( \delta = \epsilon/40 \) which shows that for every \( s \)-smooth \( f : \mathbb{R}^k \rightarrow [-1, 1] \), there is a function \( g \in \text{Net}_{tr} \) such that \( \|g - f\|_{L_2(\gamma)}^2 \leq \epsilon/4 \). Further, log \( |\text{Net}_{tr}| \leq k^{O(s^2/\epsilon^2)} \log(1/\epsilon) \).

Observe that the functions in the set \( \text{Net}_{tr} \) are not necessarily bounded. To obtain bounded \( s \)-smooth functions (i.e., the set \( \text{Net} \)), for each \( g \in \text{Net}_{tr} \), we choose an arbitrary \( s \)-smooth \( h : \mathbb{R}^k \rightarrow [-1, 1] \) such that \( \|g - h\|_{L_2(\gamma)}^2 \leq \epsilon/4 \) and include it in \( \text{Net} \). Note that the size of \( \text{Net} \) is no larger than \( \text{Net}_{tr} \). Further, from the property of \( \text{Net}_{tr} \), we have that for every \( s \)-smooth \( f \), there is a function \( g \in \text{Net} \) such that \( \|g - f\|_{L_2(\gamma)} \leq \epsilon/2 \). This finishes the proof.

□

Next, we need to turn our net of functions on \( \mathbb{R}^k \) into a net of \( k \)-linear-juntas on \( \mathbb{R}^m \). We will do this by finding an appropriate net for \( k \)-dimensional subspaces of \( \mathbb{R}^m \), and then using the net of Lemma 5.9 for each of these subspaces.

**Lemma 5.10.** There is a set \( \mathcal{E} \) of \( k \)-dimensional subspaces of \( \mathbb{R}^m \) such that

1. for every \( k \)-dimensional subspace \( E \) of \( \mathbb{R}^m \), there is some \( E' \in \mathcal{E} \) with \( \|\Pi_E - \Pi_{E'}\|_F \leq \epsilon \); and

2. \( |\mathcal{E}| \leq \left( \frac{O(k)}{\epsilon} \right)^{mk} \).

**Proof.** Let \( T \) be a \( \delta \)-net of \( S^{m-1} \) (the unit Euclidean sphere in \( \mathbb{R}^m \)) of cardinality at most \( (1/\delta)^{O(m)} \) (as described in Fact 5.8). Let \( \mathcal{E} \) be the set of all \( k \)-dimensional subspaces that are spanned by \( k \) elements of \( T \). The claimed bound on the cardinality of \( \mathcal{E} \) follows, provided we choose \( \delta \) so that \( \epsilon \leq C'k\delta \) (for an absolute constant \( C' \)).

Let \( E \) be a \( k \)-dimensional subspace of \( \mathbb{R}^m \), and let \( x_1, \ldots, x_k \) be an orthonormal basis of \( E \). Choose \( y_1, \ldots, y_k \in T \) with \( \|x_i - y_i\| \leq \delta \) for all \( i \); then the \( y_i \) are unit vectors, and for \( i \neq j \) we have

\[
|\langle y_i, y_j \rangle| = |\langle y_i, y_j \rangle - \langle x_i, x_j \rangle| \leq |\langle x_i, x_j \rangle - y_i \rangle| + |\langle y_j, x_i \rangle - y_i \rangle| \leq 2\delta.
\]

It follows that if \( Y \) is the matrix with rows \( y_i \), and if \( E' \) is the span of \( y_1, \ldots, y_k \), then \( \|Y^T Y - \Pi_{E'}\|_F^2 = \|Y Y^T - I\|_F^2 \leq 4\delta^2 k \). Hence,

\[
\|\Pi_E - \Pi_{E'}\|_F = \|X^T X - \Pi_{E'}\|_F \leq \|X^T X - Y^T Y\|_F = 2\delta \sqrt{k}.
\]

It remains to bound \( \|X^T X - Y^T Y\|_F \), and it will suffice to show that \( \|X^T X - Y^T Y\|_F = O(k\delta) \).

Now, if \( x \) and \( y \) are unit vectors with \( \|x - y\| \leq \delta \), then \( \langle x, y \rangle \geq 1 - O(\delta^2) \). It follows that \( \|x x^T - y y^T\|_F^2 = 2 - 2\langle x, y \rangle^2 \leq O(\delta^2) \). Thus, by the triangle inequality,

\[
\|X^T X - Y^T Y\|_F \leq \sum_{i=1}^k \|x_i x_i^T - y_i y_i^T\|_F = O(k\delta).
\]

□

**Proposition 5.11.** For any \( k, m \in \mathbb{N} \) and any \( s, \epsilon > 0 \), there exists a set \( \text{Net} \) of functions \( \mathbb{R}^k \rightarrow [-1, 1] \) such that

- every function in \( \text{Net} \) is \( \mathbb{L}_{C/\epsilon} \)-Lipschitz (\( C \) is the constant appearing in Fact 2.5),

- \( \text{Net} \) is an \( \epsilon \)-net for the set of \( s \)-smooth linear \( k \)-juntas on \( \mathbb{R}^m \),

- \( \log |\text{Net}| \leq k^{O(s^2/\epsilon^2)} + O(mk \log \frac{km}{\epsilon}) \), and

- every function in \( \text{Net} \) is a \( s \)-smooth linear \( k \)-junta.
Proof. Let \( \hat{\text{Net}} \) be a net for \( s \)-smooth functions on \( \mathbb{R}^k \), with the properties guaranteed by Lemma 5.9. Let \( \mathcal{E} \) be a collection of \( k \)-dimensional subspaces of \( \mathbb{R}^m \), with the properties guaranteed by Lemma 5.10 with accuracy \( \epsilon' = \epsilon^2/s \). Let Net be the set of functions of the form \( x \mapsto f(\Pi_E x) \), where \( f \in \hat{\text{Net}} \) and \( E \in \mathcal{E} \). Clearly, Net satisfies the first and last claims. Moreover, \( \log |\text{Net}| = \log |\hat{\text{Net}}| + \log |\mathcal{E}| \), which satisfies the third claim.

To check the second claim, suppose that \( f \) is an \( s \)-smooth \( k \)-Junta. Then there is some \( k \)-dimensional subspace \( \hat{E} \) and an \( s \)-smooth function \( g \) on \( \mathbb{R}^k \) such that \( f = g \circ \Pi_{\hat{E}} \). Choose \( h \in \hat{\text{Net}} \) to be \( \epsilon \)-close to \( g \) and choose \( \hat{E}' \in \mathcal{E} \) such that \( ||\Pi_{\hat{E}} - \Pi_{\hat{E}'}||_F \leq \epsilon^2/s \). Then \( h \circ \Pi_{\hat{E}'} \) belongs to Net, and satisfies

\[
||h \circ \Pi_{\hat{E}'} - f||_{L^2(\gamma)} \leq ||h \circ \Pi_{\hat{E}'} - h \circ \Pi_{\hat{E}}||_{L^2(\gamma)} + ||h \circ \Pi_{\hat{E}} - f \circ \Pi_{\hat{E}}||_{L^2(\gamma)}
\]

The second term is at most \( \epsilon \), and the first term can be bounded (using Lemma 5.7) by \( (\text{Lip } h)||\Pi_{\hat{E}'} - \Pi_{\hat{E}}|| \leq \frac{C}{\epsilon} \cdot \epsilon^2/2 \leq C \epsilon \). This proves the claim (after we change \( \epsilon \) by a constant factor).

5.2.2 Proof of the theorem

Finally, here is the application of Proposition 5.11 to the analysis of our algorithm: we show that we can replace the supremum over all linear \( k \)-juntas with the maximum over our net.

Lemma 5.12. Let Net be an \( \epsilon \)-net for \( s \)-smooth linear \( k \)-juntas on \( \mathbb{R}^m \), as guaranteed by Proposition 5.11. Let \( \hat{E} \) be a \( m \)-dimensional subspace of \( \mathbb{R}^n \) and let \( A \in \mathbb{R}^{m \times n} \) with the following two properties: (i) the rows of \( A \) span \( \hat{E} \) and (ii) \( ||A^T - I||_F \leq k \). Then, for any Lipschitz function \( f_{sm} \), we have that

\[
|\rho_{\hat{E},k,s}(f_{sm}) - \max_{h \in \text{Net}} \mathbb{E}[h(Ax) \cdot f_{sm}(x)]| \leq \frac{C' s k}{\epsilon} + \epsilon,
\]

for an absolute constant \( C' \).

Proof. Let \( Y \) be an \( m \times n \) matrix with orthonormal rows whose rows also span \( \hat{E} \) such that \( ||Y - A||_F \leq ||A^T - I||_F \) (by Lemma 5.5). For any \( h \in \text{Net} \), observe that \( h \) is \( O(s/\epsilon) \)-Lipschitz. Thus, Lemma 5.7 and the Cauchy-Schwarz inequality imply that

\[
|\mathbb{E}_x[h(Ax) \cdot f_{sm}(x)] - \mathbb{E}_x[h(Yx) \cdot f_{sm}(x)]| \leq ||h \circ A - h \circ Y||_{L^2(\gamma)} \leq \frac{O(1) \cdot s}{\epsilon} \cdot ||A - Y|| \leq \frac{O(1) s k}{\epsilon}.
\]

Thus, to prove the claim, it suffices to show that

\[
|\rho_{\hat{E},k,s}(f_{sm}) - \max_{h \in \text{Net}} \mathbb{E}[h(Yx) \cdot f_{sm}(x)]| \leq \epsilon.
\]

Now, recall that \( \rho_{\hat{E},k,s} \) involves a maximum over all \( s \)-smooth linear \( k \)-juntas on \( \hat{E} \). On the other hand, the rows of \( Y \) are an orthonormal basis for \( \hat{E} \); hence, as \( h \) ranges over all \( s \)-smooth linear \( k \)-juntas on \( \mathbb{R}^m \), \( h \circ Y \) ranges over all \( s \)-smooth \( k \)-linear juntas on \( \hat{E} \). Hence,

\[
\rho_{\hat{E},k,s}(f_{sm}) - \max_{h \in \text{Net}} \mathbb{E}[h(Yx) \cdot f_{sm}(x)] = \max_{h \in J_{\mathbb{R}^m,k,s}} \mathbb{E}[h(Yx) \cdot f_{sm}(x)] - \max_{h \in \text{Net}} \mathbb{E}[h(Yx) \cdot f_{sm}(x)]
\]

The claim now follows from the properties of Net, because for every \( h \in J_{\mathbb{R}^m,k,s} \) there is an \( \epsilon \)-close (in \( L^2(\gamma) \)) element of Net, and conversely for every \( h \in \text{Net} \) there is an \( \epsilon \)-close element of \( J_{\mathbb{R}^m,k,s} \).

Proof of Theorem 5.2: Let Net be the set of functions guaranteed by Proposition 5.11 (with smoothness parameter \( s \) and error parameter \( \epsilon/4 \)). Let us also set \( \nu = \epsilon^2/(100C') \) for the constant \( C' \) appearing in Lemma 5.12.

Let us now invoke algorithm Implicit Projection with smoothness parameter \( u = \nu/s \), Lipschitz parameter \( L = O(s/\nu) \), the error parameter \( \nu \) and junta arity parameter \( k \). Lemma 5.1 guarantees that with probability 9/10, we get a matrix \( \hat{W} \) and points \( x_1, \ldots, x_M \) such that the following conditions are satisfied: Let \( B^T \) be the matrix where the \( j \)-th row is \( \nabla f_{sm}(x_j) \). Let \( \hat{E} \) be the row span of \( B^T \).
1. $||\hat{f} - \hat{W}B^T B\hat{W}^T||_F \leq \nu/2$. Here $\hat{f}$ is the identity matrix in $m$ dimensions where $m = \text{dim}(\hat{E})$.

2. $\rho_{\hat{E},k,s}(f_{\text{sm}}) \geq \rho_{\hat{E}^r,k,s}(f_{\text{sm}}) - \frac{\nu}{200}$.

Now, combining with Lemma 5.12 we have that

$$\left| \rho_{\hat{E},k,s}(f_{\text{sm}}) - \max_{h \in \text{Net}} \mathbb{E}[h(\hat{W}B^T x) \cdot f_{\text{sm}}(x)] \right| \leq \frac{C_s \cdot \nu}{\epsilon} + \frac{\epsilon}{4} < \frac{51 \cdot \epsilon}{200}.$$  

Combining this with the second item above, we have

$$\left| \rho_{\hat{E}^r,k,s}(f_{\text{sm}}) - \max_{h \in \text{Net}} \mathbb{E}[h(\hat{W}B^T x) \cdot f_{\text{sm}}(x)] \right| \leq \frac{52 \cdot \epsilon}{200}. \quad (14)$$

Thus, for our purposes, it suffices to (approximately) compute $\max_{h \in \text{Net}} \mathbb{E}[h(\hat{W}B^T x) \cdot f_{\text{sm}}(x)]$. Towards this, consider any fixed $h \in \text{Net}$. We set $T = O(\epsilon^{-2} \log(1/\zeta))$ where $\zeta = 1/(10 \cdot |\text{Net}|)$. Sample $T$ points from the standard Gaussian $\gamma_n$—call these points $z_1, \ldots, z_T$. By applying the Chernoff bounds, observe that for any $h \in \text{Net}$, with probability $1 - \zeta$,

$$\left| \mathbb{E}_x[h(\hat{W}B^T x) \cdot f_{\text{sm}}(x)] - \frac{1}{T} \sum_{j=1}^{T} h(\hat{W}B^T z_j) \cdot f_{\text{sm}}(z_j) \right| \leq \epsilon/4.$$  

From a union bound, it follows that with probability $9/10$,

$$\left| \max_{h \in \text{Net}} \mathbb{E}_x[h(\hat{W}B^T x) \cdot f_{\text{sm}}(x)] - \max_{h \in \text{Net}} \frac{1}{T} \sum_{j=1}^{T} h(\hat{W}B^T z_j) \cdot f_{\text{sm}}(z_j) \right| \leq \epsilon/4. \quad (15)$$

Combining (15) and (14), we get

$$\left| \rho_{\hat{E}^r,k,s}(f_{\text{sm}}) - \max_{h \in \text{Net}} \frac{1}{T} \sum_{j=1}^{T} h(\hat{W}B^T z_j) \cdot f_{\text{sm}}(z_j) \right| < \frac{2 \epsilon}{3}.$$  

Thus, it suffices to compute the quantity

$$\text{Corr} = \max_{h \in \text{Net}} \frac{1}{T} \sum_{j=1}^{T} h(\hat{W}B^T z_j) \cdot f_{\text{sm}}(z_j),$$

up to additive error $\pm \epsilon/3$ and upper bound the query complexity of computing this estimate. Observe that computing $(f_{\text{sm}}(z_j))_{j=1}^{T}$ requires $T$ queries. Using Lemma 5.1 we have

$$||\hat{W}||_2 \leq \frac{20k}{\nu} := \Delta$$

Set $\theta = \frac{\epsilon^2}{200 \cdot 2 \Delta \cdot \sqrt{m}}$. Here $C$ is the constant appearing in Fact 5.8. We now invoke algorithm Project-on-gradient from Lemma 2.17. Then, we get that for any $z_j$ (for $1 \leq j \leq T$),

$$\Pr_{x \sim \gamma_n} [|\text{Est}(x_i, z_j) - \langle \nabla f_{\text{sm}}(x_i), z_j \rangle | > \theta ] \leq \frac{1}{200 T \cdot m}.$$  

Further, we can compute $\pm \theta$ estimate to $\text{Est}(x_i, z_j)$ (with confidence $1 - \frac{1}{200 T \cdot m}$) where the query complexity is $\text{poly}(T \cdot m, 1/\theta)$. This means that with probability 0.99, for each $1 \leq j \leq T$ and $1 \leq i \leq m$, we have $\pm \theta$ estimates (denoted by $\chi_{i,j}$) for each $\langle \nabla f_{\text{sm}}(x_i), z_j \rangle$. In other words, for each $1 \leq j \leq T$, we get a vector $\Xi_j$ which satisfies

$$||\Xi_j - B^T z_j|| \leq 2 \theta \sqrt{m}.$$
Since $\|\hat{W}\| \leq \Delta$, this means that for all $1 \leq j \leq T$,

$$\|\hat{W}\xi_j - \hat{W}B^T \zeta_j\| \leq 2\theta \sqrt{m\Delta} = \frac{\epsilon^2}{100C \cdot s}.$$  

Since $h \in \text{Net}$ is $Cs/\epsilon$-Lipschitz, this implies that for each $1 \leq j \leq T$,

$$|h(\hat{W}\xi_j) - h(\hat{W}B^T \zeta_j)| \leq \frac{\epsilon}{100}.$$  

Consequently, this gives a $\pm \epsilon/100$ additive estimate of the quantity

$$\frac{1}{T} \sum_{j=1}^{T} h(\hat{W}B^T \zeta_j) \cdot f_{sm}(\zeta_j).$$  

By combining (14) and (15), we thus obtain a $\pm \epsilon$-additive estimate of $\rho_{R_{k,s}}(f_{sm})$. It remains to bound the query complexity of the algorithm. The query complexity of the algorithm implicit projection (from Lemma 5.1) is $\text{poly}(k, 1/u, 1/\nu, L)$ where $\nu = \epsilon^2/(100Cs')$ ($C'$ is the constant appearing in Lemma 5.12). Thus, the query complexity of this part is $\text{poly}(k, s, L, 1/\epsilon)$.

For the hypothesis testing part, the query complexity can be bounded as follows:

1. We make $T$ queries to $f_{sm}$ where $T = O(\epsilon^{-2} \log |\text{Net}|)$.

2. For each $1 \leq j \leq m$ and $1 \leq i \leq T$, we compute a $\pm \theta$ approximation to $\text{Est}(x_i, \zeta_i)$ -- the query complexity of each is $\text{poly}(T \cdot m, 1/\theta)$.

Thus, the total query complexity is bounded by $\text{poly}(T, m, 1/\theta)$. Using the fact that $m \leq M$ (where $M$ is set in algorithm implicit projection) and plugging in the value of the parameters, we get the final bound on the query complexity.

Finally, we remark that our analysis so far was based on assuming that we have exact oracle access to $f_{sm}$. However, we only have oracle access to $f$ and approximate oracle to $f_{sm}$ (via Lemma 4.1). To address this issue, we observe that the algorithm implicit projection only uses the oracle to $f$ and not to $f_{sm}$ (the only invocation of these oracles is when we call the routine compute-inner-product). In the hypothesis testing part, (i) we only use the oracle to $f$ when we invoke the algorithm project-on-gradient. (ii) we use the oracle for $f_{sm}$ when we approximate $\text{Corr}$ to error $\pm \epsilon/3$. However, it is easy to see that for this, it suffices to have an oracle for $f_{sm}$ with (say) $O(\epsilon^{-1.5})$ additive accuracy. By Lemma 4.1 this can be simulated with an oracle for $f$ with $O(\epsilon^{-3})$ overhead given an oracle to $f$. This finishes our proof.

\[\square\]

6 Learning the linear-invariant structure

The proof of Theorem 1.4 is essentially the same as the proof of Theorem 4.2, the only difference is that instead of outputting the maximum correlation value of a function in the net, we output the function that achieves that value.

**Proof of Theorem 1.4:** Let $\text{Net}$ be the set of functions guaranteed by Proposition 5.11. As in the proof of Theorem 4.2, for each $h \in \text{Net}$ we can compute $E_{x}[h(\hat{W}B^T x) \cdot f_{sm}(x)]$ to error $\pm \epsilon/4$ with confidence $1 - \delta$ using $O(\epsilon^{-2} \log(1/\delta))$ queries. With the same $\delta$ as in that proof, with probability $9/10$ we can simultaneously estimate $E_{x}[h(\hat{W}B^T x) \cdot f_{sm}(x)]$ to error $\pm \epsilon/8$ for all $h \in \text{Net}$. If $\hat{h}$ is a choice of $h \in \text{Net}$ maximizing our estimate of $E_{x}[h(\hat{W}B^T x) \cdot f_{sm}(x)]$, it follows that

$$E_x[\hat{h}(\hat{W}B^T x) \cdot f_{sm}(x)] \geq \max_{h \in \text{Net}} E_x[h(\hat{W}B^T x) \cdot f_{sm}(x)] - \frac{\epsilon}{4}.$$  

21
Now, in the proof of Theorem 4.2 we showed that
\[
\max_{h \in \text{Net} x} \mathbb{E}[h(\hat{W}B^T x) \cdot f_{sm}(x)] \geq \rho_{\mathbb{R}^n, k, s}(f_{sm}) - \frac{\epsilon}{2},
\]
and so applying Lemma 4.1 show that the algorithm that output \( \hat{h} \) satisfies the claim. □

A Perturbation bounds for subspaces and smooth functions

Lemma A.1. If $E$ and $E'$ are two subspaces of $\mathbb{R}^n$ then for any Lipschitz function $f : \mathbb{R}^n \to \mathbb{R}$,

$$E|\mathcal{A}_E f(x) - \mathcal{A}_{E'} f(x)| \leq \sqrt{2c}||E - E'||_F.$$ 

Here $c$ is the Lipschitz constant of $f$.

Proof. Since we can express $\mathcal{A}_{E'} f(x)$ as

$$\mathcal{A}_{E'} f(x) = E[f(\Pi_{E}x + \Pi_{E'}z + (\Pi_{E'} - \Pi_{E})x + (\Pi_{E'} - \Pi_{(E')}z)z)],$$

the Lipschitz property allows us to bound

$$|\mathcal{A}_E f(x) - \mathcal{A}_{E'} f(x)| \leq c E\left[|| (\Pi_{E'} - \Pi_{E})x + (\Pi_{E'} - \Pi_{(E')}z)z||\right].$$

Since $\Pi_{E'} = I - \Pi_{E}$ (and similarly for $E'$), the right hand side is just $c E\left[|| (\Pi_{E'} - \Pi_{E})(x - z)||\right]$. Observe that if $x$ and $z$ are distributed as a standard Gaussian, then $x - z$ is distributed as $N(0, \sqrt{2})$. Hence,

$$E\left[|\mathcal{A}_E f(x) - \mathcal{A}_{E'} f(x)| \leq \sqrt{2c} E\left[||(\Pi_{E'} - \Pi_{E}) z||\right].$$

Finally, one can easily check that for any matrix $A$, $E||Az||^2 = ||A||^2_F$; by Jensen’s inequality, it follows that $E||AZ|| \leq ||A||_F$ which finishes the proof. 

□

Lemma A.2. If $E$ and $E'$ are two subspaces of $\mathbb{R}^n$ such that $||\Pi_{E} \Pi_{(E')} || < 1$, then there exists a subspace $\hat{E} \subset E'$ with $\dim \hat{E} = \dim E$ such that

$$||\Pi_{\hat{E}} - \Pi_{E}||_F^2 \leq 8||\Pi_{E} \Pi_{(E')} ||^2_F.$$ 

Proof. Let $k = \dim E$ and define $A = \Pi_{E} \Pi_{E'}$. We begin with the following simple claim.

Claim A.3. The matrix $A$ has exactly $k$ non-zero singular values.

Proof. Observe that it suffices to analyze the eigenvalues of $A \cdot A^T$. Towards this, we observe that for any $w \in E^\perp$, $w^T \cdot A \cdot A^T \cdot w = 0$. On the other hand, for any $w \in E$,

$$w^T \cdot A \cdot A^T \cdot w = w^T \Pi_{E} \Pi_{E'} \Pi_{E} \cdot w = w^T \Pi_{E} \cdot w \geq w^T \cdot \Pi_{E'} \cdot w - w^T \cdot \Pi_{E} \cdot \Pi_{(E')} \cdot w > 0.$$ 

The last inequality uses that $w \in E$ and $||\Pi_{E} \Pi_{(E')} || < 1$. This implies that for all $w \in E$, $w^T \cdot A \cdot A^T \cdot w > 0$. Consequently, $A \cdot A^T$ (and hence $A$) has exactly $k$ non-zero eigenvalues. □
Let $UDV^T = \Pi_E \Pi_{E'} = A$ be the singular value decomposition of $A$ and observe that we can assume that $D$ is $k \times k$ diagonal matrix (whose diagonal elements are positive). Let the columns of $U$ be $\{u_1, \ldots, u_k\}$ and the columns of $V$ be $\{v_1, \ldots, v_k\}$. Then, $\{u_1, \ldots, u_k\}$ is an orthonormal basis for $E$ and $\{v_1, \ldots, v_k\}$ is an orthonormal basis for a subspace $\tilde{E}$ of $E'$. Observe that $\Pi_E = UU^T$ and $\Pi_{\tilde{E}} = VV^T$. Thus,

$$\|\Pi_E - \Pi_{\tilde{E}}\|_F^2 = \|UU^T - UDV^T\|_F^2 = \|U^T - DV^T\|_F^2 = \sum_{i=1}^k \|d_i v_i - u_i\|_2^2.$$ 

For fixed unit vectors $v$ and $u$, $\|dv - u\|_2^2$ is minimized when $d = \langle u, v \rangle$, in which case $\|dv - u\|_2^2 = 1 - \langle u, v \rangle^2$. If $d \geq 0$, $\|dv - u\|_2^2 \geq \frac{1}{2} \|v - u\|_2^2$. Hence,

$$\|\Pi_E - \Pi_{\tilde{E}}\|_F^2 = \|UU^T - UU^T\|_F^2 \geq \frac{1}{2} \sum_{i=1}^k \|u_i - v_i\|_2^2. \quad (16)$$

Finally,

$$\|\Pi_E - \Pi_{\tilde{E}}\|_F^2 = \|UU^T - VV^T\|_F^2 \leq 2\|UU^T - UV^T\|_F^2 + 2\|UV^T - VV^T\|_F^2 = 2\|U^T - V^T\|_F^2 + 2\|U - V\|_F^2 = 4 \sum_{i=1}^k \|u_i - v_i\|_2^2. \quad (17)$$

Combining this with (16), we have $\|\Pi_E - \Pi_{\tilde{E}}\|_F^2 \leq 8\|\Pi_E - \Pi_{\tilde{E}}\|_F^2.$

**Corollary A.4.** For any subspaces $E$ and $E'$ of $\mathbb{R}^n$ with $\|\Pi_E \Pi_{E'}\| < 1$, Lipschitz function $f : \mathbb{R}^n \rightarrow [-1, 1]$ and $s > 0$,

$$\rho_{E', k, s}(f) \geq \rho_{k, E, s}(f) - 4c\|\Pi_E \Pi_{E'}\|_F,$$

where $c$ is the Lipschitz constant of $f$.

**Proof.** Fix $\delta > 0$. Then, we know that there exists $g \in \mathcal{F}_{E, k, s}$ such that for $\delta > 0$,

$$E_x[f(x)g(x)] = E_x[f(x)\mathcal{A}_E g(x)] \geq \rho_{E, k, s} - \delta. \quad (18)$$

Now, let $\epsilon = \|\Pi_E \Pi_{E'}\|_F$ (by assumption $\epsilon < 1$). Then, using Lemma A.2, it follows that there exists a subspace $\tilde{E}$ of $E'$ with $\text{dim}(E) = \text{dim}(\tilde{E})$ such that $\|\Pi_E - \Pi_{\tilde{E}}\|_F \leq 2\sqrt{2}\epsilon$. Since $f$ is $c$-Lipschitz, it follows that

$$E_x[|\mathcal{A}_E f(x) - \mathcal{A}_{\tilde{E}} f(x)|] \leq \sqrt{2c\|\Pi_E - \Pi_{\tilde{E}}\|_F} \leq 4c\|\Pi_E \Pi_{E'}\|_F. \quad (19)$$

The first inequality uses Lemma A.1 and the second inequality uses Lemma A.2. Thus, it follows that

$$E_x[g(x)\mathcal{A}_E f(x)] - E_x[g(x)\mathcal{A}_{\tilde{E}} f(x)] \leq E_x[g(x)(\mathcal{A}_E f(x) - g(x)\mathcal{A}_{\tilde{E}} f(x))]. \quad (20)$$

Now, observe that $g' = \mathcal{A}_{E} g \in \mathcal{F}_{E', k, s}$ – this is a consequence of Item 2 in Proposition 2.8. Using (17), it follows that

$$\rho_{E', k, s}(f) \geq E_x[g'(x)f(x)] \geq E_x[g(x)\mathcal{A}_E f(x)] - 4c\|\Pi_E \Pi_{E'}\|_F \geq \rho_{E, k, s} - 4c\|\Pi_E \Pi_{E'}\|_F - \delta.$$

Now taking $\delta \to 0$, we have the claim. 

\[\Box\]
B Stability of the pseudoinverse

In this section, we prove a stability result for pseudoinverse of square matrices. We first recall the well-known Davis-Kahan theorem – the precise formulation we are using is Theorem VII. 3. 2 from [4].

**Theorem B.1.** Let \( A, B \in \mathbb{C}^{n \times n} \) be Hermitian matrices. Let \( S_1 = [a, b] \) and \( S_2 = \mathbb{R} \setminus [a - \delta, b + \delta] \) for \( \delta > 0 \). Let \( E_1 \) be the subspace spanned by the eigenvectors of \( A \) corresponding to eigenvalues lying in \( S_1 \). Similarly, \( E_2 \) is the subspace spanned by the eigenvectors of \( B \) corresponding to eigenvalues lying in \( S_2 \). Then, for any unitarily invariant norm \( \| \cdot \| \) (such as the \( \| \cdot \|_2 \) or \( \| \cdot \|_F \) ),

\[
\| \Pi_{E_1} \Pi_{E_2} \| \leq \frac{\pi}{2\delta} \| A - B \|.
\]

Using the Davis-Kahan theorem, we prove the following result. Before we do that, we use the following simple fact.

**Fact B.2.** Let \( R \) be a psd matrix and \( W \) be the space spanned by eigenvectors with eigenvalues in the range \( [\lambda - \delta, \lambda + \delta] \) where \( \lambda > 2\delta \). Then, for any \( w \in W \)

\[
\| R^{-1} w - \frac{1}{\lambda} w \|_2 \leq \frac{2\delta}{\lambda^2} \| w \|_2.
\]

**Proof.** Express \( w = \sum_i \alpha_i w_i \) (where \( \{w_i\} \) are orthonormal eigenvectors of \( R \)). If \( \lambda_i \) is the eigenvalue corresponding to \( w_i \), then note that

\[
R^{-1} w = \sum_i \frac{\alpha_i}{\lambda_i} w_i.
\]

This implies that

\[
R^{-1} w - \frac{w}{\lambda} = \sum_i \alpha_i w_i \cdot \left( \frac{1}{\lambda} - \frac{1}{\lambda_i} \right)
\]

From this, it follows that

\[
\| R^{-1} w - \frac{1}{\lambda} w \|_2 \leq \frac{2\delta}{\lambda^2} \| w \|_2.
\]

**Lemma B.3.** Let \( A, \tilde{A} \in \mathbb{R}^{n \times n} \) be psd matrices. Let \( \eta \geq 0 \) and \( V \) denote the subspace spanned by the eigenvalues of \( A \) in \( [\eta, \infty) \). Then,

\[
\| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta/2}^{-1}) \cdot \Pi_V \| \leq \frac{20\| A \|_F \sqrt{\| A - \tilde{A} \|_2}}{\eta^{5/2}}.
\]

**Proof.** Define \( B = (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta/2}^{-1}) \cdot \Pi_V \). First of all, observe that for all \( v \in V^\perp \), \( Bv = 0 \). Next, consider any eigenvector \( v \) of \( A \) with corresponding eigenvalue \( \lambda \in [\eta, \infty) \). For a choice of \( \delta > 0 \) to be fixed later, define \( W \) to be the span of the eigenvectors of \( \tilde{A} \) with eigenvalues in \( [\lambda - \delta, \lambda + \delta] \). Then, Theorem B.1 implies that \( v_{W^\perp} \) (i.e., the projection of \( v \) on \( W^\perp \)) satisfies

\[
\| v_{W^\perp} \|_2 \leq \frac{\pi}{2\delta} \| A - \tilde{A} \|_2.
\]

Consequently, as the largest singular value of \( \tilde{A}_{\geq \eta/2}^{-1} \) is at most \( 2/\eta \),

\[
\| \tilde{A}_{\geq \eta/2}^{-1} v_{W^\perp} \|_2 \leq \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2.
\]

On the other hand, using Fact B.2.
\[
\| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta}^{-1}) \cdot \Pi_V v \|_2 = \| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta}^{-1}) v \|_2 \\
\leq \| v - \tilde{A}_{\geq \eta}^{-1} v \|_2 + \| \tilde{A}_{\geq \eta}^{-1} v \|_2 \\
\leq \| v - \tilde{A}_{\geq \eta}^{-1} v \|_2 + \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 \text{ using (21)} \\
\leq \| v - \tilde{A}_{\geq \eta}^{-1} v \|_2 + \frac{2 \delta}{\eta^2} \| v \|_2 + \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 \text{ using Fact B.2} \\
= \frac{\| v - \tilde{A}_{\geq \eta}^{-1} v \|_2 + 2 \delta}{\eta^2} \| v \|_2 + \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 \\
\leq \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 + \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 + \frac{2 \delta}{\eta^2}.
\]

The last inequality applies (20) and the fact that \( v \) is a unit vector. Next, we observe that \( \lambda \geq \eta/2 \) and thus, the above inequality implies

\[
\| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta}^{-1}) \cdot \Pi_V v \|_2 \leq \frac{2 \pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 + \frac{\pi}{\eta \cdot \delta} \| A - \tilde{A} \|_2 + \frac{8 \delta}{\eta^2}.
\]

By an appropriate choice of \( \delta = \sqrt{\| A - \tilde{A} \|} \), we have

\[
\| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta}^{-1}) \cdot \Pi_V v \|_2 \leq 20 \sqrt{\| A - \tilde{A} \|_2}.
\]

Suppose \( u \) is any unit vector in \( V \). Then, it follows from the above equation that

\[
\| (A_{\geq \eta}^{-1} - \tilde{A}_{\geq \eta}^{-1}) \cdot \Pi_V v \|_2 \leq 20 \sqrt{\dim(V)} \sqrt{\| A - \tilde{A} \|_2}.
\]

Finally, observe that \( \sqrt{\dim(V)} \leq \frac{\| A \|}{\eta} \). This finishes the proof.
