Negishi-type Catalyst-Transfer Polymerization (NCTP) of electron-deficient monomers has been attempted for the first time. Imide or ketone groups in such monomers show an excellent electron-deficient property. However, these functional groups cannot generally tolerate towards highly reactive Grignard reagents. In this work, we applied a zincate complex with lower basicity, 

\[ \text{tBu}_4\text{ZnLi}_2 \]

for the polymerization of a naphthalene-diimide-containing monomer. Zinc-halogen exchange reaction was quantitatively conducted at 60 °C for 1 h without any protection of the imide group. Then, the polymerization was carried out by adding the Pd catalyst to afford an electron-deficient polymer, PTNDIT \((M_n = 8,400\) and \(\bar{D} = 1.35\)).

**Keywords**: Catalyst-Transfer, Protection-free, Zincate complex, \(n\)-type polymer.

1. Introduction

Polymer solar cells (PSCs) [1] and organic field-effect transistors (OFETs) [2] are attractive devices with the properties of light weight, flexible and low-cost by fabricating on the transparent films such as polyimides, polyethers and polyesters. \(\pi\)-Conjugated polymers (CPs) are promising candidates for the active layer of these devices because of its high hole and/or electron mobility and high solubility toward organic solvents. To synthesize CPs, the polycondensation is conducted by cross coupling reactions such as Suzuki coupling and Stille coupling reactions. However, it is difficult to control not only the molecular weight (MW) but also dispersity \((D)\) of each polymer obtained in a step-growth manner, theoretically. The effect of the MW and \(D\) of CPs has already been discussed by several researchers and they concluded that optimum MW [3] and low \(D\) [4,5] of CPs strongly enhance the properties of optoelectronic devices, depending on each polymer structure and/or the morphology in the active layer film.

In the past decade, with regard to \(p\)-type semiconducting materials such as poly(3-hexylthiophene) (P3HT), controlled synthesis was accomplished by catalyst-transfer polymerization. Yokozawa and coworkers [6] and McCullough and coworkers [7] established a Kumada Catalyst-Transfer Polymerization (KCTP) system, independently, and controlled the MW and \(D\) values of regioregular P3HT. In addition, by using KCTP, a wide variety of electron-donating monomers becomes available for polymerization and a lot of block copolymers [7b,8] and end-functional polymers [9] could easily be synthesized. However, taking into account the application of CPs to all-polymer solar cells (All-PSCs) [10], in which the active layer is binary blend of \(p\)-type polymer and \(n\)-type polymer, the general controlled polymerization method of not only electron-donating monomer but also electron-deficient monomer is absolutely necessary. However, there are only a few successful examples of controlling the polymerization of electron-deficient monomer containing electron...
withdrawing groups. Poly(pyridine) [11] and poly(benzotriazole) [12] synthesized by KCTP have already been reported. However, the application of these polymers are unfortunately limited. The polymers containing naphthalene-diimide [13] or perylene-diimide [14], which show high electron mobility, were synthesized by Kiriy and coworkers by catalyst-transfer polymerization of the anion-radical monomer in the presence of the Pd or Ni catalyst. However, the obtained polymers possess high $D$ values even though they achieve high enough MWs of the polymers. A major issue in the polymerization of electron-deficient monomer would be their increased size and polarization. While the effective catalyst-transfer is the key factor to control the MW and $D$ values, these complicated monomer structure induces the undesirable termination or chain-transfer reaction. Moreover, one of other big problems is low tolerability of the functional groups such as carbonyl group in the monomer precursor against the Grignard reagents [15].

In 2012, we have established Negishi-type Catalyst-Transfer Polymerization (NCTP) using chemo-selective and bulky zincate complex, $^t$Bu$_4$ZnLi$_2$, and succeeded in purification-free and protection-free polymerization of a thiophene monomer [16].

Furthermore, after the detailed investigation of the phosphorous ligands of the Ni catalyst, P3HTs with controlled MW and extremely low $D$, as well as well-defined related block copolymers were successfully synthesized [17]. In this report, we focused on the controlled polymerization of electron-deficient naphthalene-diimide-containing monomer by extending our new NCTP system for the first time.

2. Experimental

2.1 Materials

Tetrahydrofuran (THF, dehydrated, stabilizer-free, 99.5%, Wako Pure Chemical Industries Ltd.) was dried over sodium benzophenone and distilled before use under a nitrogen atmosphere. $^t$Bu$_4$ZnLi$_2$ (0.215 M in THF solution) was kindly donated by Tosoh Finechem Corporation, which could also be synthesized according to the previous report [18]. All other reagents were purchased from Aldrich, Japan or Tokyo Chemical Industry Co., Ltd., Wako Pure Chemical Industries, Ltd. and used as received. Dihalogenated monomer precursors (Br-TNDIT-Br and I-TNDIT-I) were synthesized by general bromination or iodination procedures with $N$-bromosuccinimide [13a] or $N$-iodosuccinimide, respectively.

2.2 Measurement

$^1$H NMR spectra were recorded on a JEOL JNM-ECX400 spectrometer at 25 °C or 40 °C. Deuterated chloroform or tetrachloroethane were used as a solvent. Size exclusion chromatography (SEC) was measured on a JASCO GULLIVER 1500 equipped with a pump, an absorbance detector (UV, $\lambda = 254$ nm), and three polystyrene gel columns, based on a conventional calibration curve using polystyrene standards. CHCl$_3$ (40 °C) was used as a carrier solvent at the flow rate of 1.0 mL/min.
2.3 General procedure for Negishi-type catalyst-transfer polymerization.

The NCTP was carried out in THF at 60 °C under a nitrogen atmosphere using Pd catalyst. In a typical experiment (Run 3), I-TNDIT-I (83.7 mg, 0.0618 mmol) and trimethoxybenzene (5.0 mg, 0.030 mmol) as an internal standard were placed in a 20 mL two-necked flask purged with a nitrogen atmosphere. After dissolving I-TNDIT-I in THF (15 mL), a THF solution of tBu4ZnLi2 (0.215 M x 0.07 mL = 0.016 mmol) was added at room temperature and stirred at 60 °C for 1 h to afford a THF solution of zincate complex-type monomer. Finally, the Pd catalyst (0.0061 mmol) solution (5 mL), which was prepared in another batch by mixing Pd2(dba)3 (5.6 mg, 0.0061 mmol) and tri(o-tolyl)phosphine (17.4 mg, 0.057 mmol) in THF (5 mL), was added to start the polymerization at 60 °C and stirred for 3 h, followed by quenching with a 5M HCl solution (1 mL). The quenched solution was poured into a large amount of methanol/H2O (150 mL/75 mL) to precipitate the polymer. After filtration, the sample was purified by soxhlet extraction with methanol, acetone, and then CHCl3. After drying under vacuum, the crude PTNDIT was obtained (25.6 mg, 38%, Mn (SEC) = 8,400, D = 1.35). 1H NMR (C2D2Cl4): δ 0.90 (12H), 1.10-1.53 (80H), 2.06 (2H), 4.17 (4H), 7.40 (4H), 8.87 ppm (2H).

Table 1. Synthetic results of PTNDIT catalysed by Pd catalysts.

| Run | X  | Pd Cat. | Ligand            | Mn,a | Đ,a |
|-----|----|---------|-------------------|------|-----|
| 1   | Br | Pd2(dba)3 | P(o-Toly)3        | 7,700| 1.45|
| 2   | Br | -       | -                 | 5,600| 1.29|

3. Results and Discussion

3.1 Zinc-halogen exchange reaction

First of all, Zn-X exchange reaction between X-TNDIT-X and tBu4ZnLi2 were conducted in THF at 60 °C for 1 h as shown in Scheme 1. After the quenching with HCl, H-TNDIT-X were quantitatively obtained (Figure 1), which indicates that Zn-X exchange reaction was successfully proceeded without any decomposition or side reactions of imide groups in the monomer.

Figure 1. 1H NMR spectra of (a) H-TNDIT-Br and (b) H-TNDIT-I.

3.2 Polymerization

The polymerization of the monomer was carried out at 60 °C for 3 h and the results, targeting the same MW (Mn = 10,000), were summarized in Table 1.

Table 1. Synthetic results of PTNDIT catalysed by Pd catalysts.

| Run | X  | Pd Cat. | Ligand            | Mn,a | Đ,a |
|-----|----|---------|-------------------|------|-----|
| 1   | Br | Pd2(dba)3 | P(o-Toly)3        | 7,700| 1.45|
| 2   | Br | -       | -                 | 5,600| 1.29|

| 6   | I  | Pd(OAc)2 | P(o-Toly)3        | 5,500| 1.24|

*a Mn, and Đ values of PTNDIT were determined by SEC using polystyrene standards. *2-(di-tert-butyolphosphino)biphenyl.

3.2 Polymerization

The polymerization of the monomer was carried out at 60 °C for 3 h and the results, targeting the same MW (Mn = 10,000), were summarized in Table 1.

First, we tried to start polymerization of Br-TNDIT-Br by Ni(dppe)Cl2 which gives good results in previous report by Kiriy and coworker [13a,b]. However, only the oligomer or monomer were obtained in our NCTP system. On the other hand, Pd2(dba)3 and P(o-Toly)3 which are commonly used in stille coupling or Suzuki coupling afforded a PTNDIT with relatively high MW and moderate D (Mn = 7,700, D = 1.45) (Run 1). Kiriy and coworker also reported that Pd catalyst with electron-rich and bulky ligand such as P'tBu3 accomplished strong interaction and effective intramolecular catalyst-transfer [13c].
Therefore, chloro[(tri-tert-butylphosphine)-2-(2-aminobiphenyl)] palladium(II) (P(’Bu)3 Pd G2) was then adopted and resulted in lower $D$ which indicates that strong interaction has been generated in catalyst-transfer, however, leading to lower MW unfortunately, as compared to Run 1 (Run 2). We speculate that the steric hindrance of both reactive sites of the monomer and P’Bu3 with Pd catalyst prevents an effective transmetalation in the cross coupling cycle. Next, we tried to polymerize I-TNDIT-I with several Pd catalysts and almost the same tendency as Br-TNDIT-Br was observed. In Run 3, the highest MW was achieved ($M_n = 8,400, D = 1.35$) using Pd$_2$(dba)$_3$ and P(o-Tolyl)$_3$. SEC UV trace clearly shows the existence of the polymeric product (Figure 2). From $^1$H NMR spectroscopy (Figure 3), the product was clearly identified and all the signals could be assigned, indicating the absence of decomposition or side reactions of reactive imide groups in the monomer.

However, MW was decreased when Pd catalyst with bulky ligands were adopted (Run 4 and Run 5) even though PTNDIT with lower $D$ was obtained. In the case of using Pd(OAc)$_2$ as another Pd catalyst, lower MW compared with Run 3 and low $D$ were observed (Run 6).

4. Conclusion

In conclusion, we have newly performed the NCTP of electron-deficient naphthalene-diimide containing monomer to synthesize the typical $n$-type polymer. When the mixed solution of Pd$_2$(dba)$_3$ and P(o-Tolyl)$_3$ was adopted for polymerization, the highest MW ($M_n = 8,400$) was accomplished with relatively low $D$ (1.35).
