E-mail: cpallis@ucy.ac.cy

We show how we can implement chaotic inflation in the context of supergravity by conveniently selecting the functional form of a strong enough non-minimal coupling between the inflaton and the Ricci scalar curvature. The procedure can be applied when a gauge singlet or non-singlet inflaton is coupled to another singlet superfield within linear-quadratic, trilinear or bilinear superpotential terms. The tachyonic instability occurring along the direction of the accompanying non-inflaton field can be cured by expanding the kinetic part of the frame function up to the fourth order in powers of the various fields. In the case of a gauge non-singlet inflaton, though, a conjugation symmetry has to be imposed on these terms in order for the flatness of the inflationary potential is maintained. On the other hand, some of these terms assist us to precisely reconcile the resulting scalar spectral index with the current PLANCK measurements while the other inflationary observables are in agreement with data.
1. Introduction

Non-minimal (chaotic) inflation (nMI) is a class of inflationary models which arises in the presence of a strong enough non-minimal coupling function between the inflaton field and the Ricci scalar curvature. In this talk, which is based on Refs. [1–4], we first briefly review the basic ingredients of nMI in a non-Supersymmetric (SUSY) framework (Sec. 1.1) and constrain the parameters of two typical models in Sec. 1.3 taking into account the observational requirements described in Sec. 1.2. Throughout the text, the subscript ,χ denotes derivation with respect to (w.r.t) the field χ and we follow the conventions of Ref. [1].

1.1 Coupling non-Minimally the Inflaton to Gravity

The action of an inflaton ϕ with potential \( V_I(ϕ) \) non-minimally coupled to Ricci scalar \( R \) through a coupling function \( f_R(ϕ) \), in the Jordan frame (JF), takes the form:

\[
S = \int d^4x \sqrt{-g} \left( -\frac{1}{2} m_p^2 f_R(ϕ) R + \frac{f_K(ϕ)}{2} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi - V_I(ϕ) \right),
\]

(1.1)

where \( m_p = 2.44 \cdot 10^{18} \) GeV is the reduced Planck mass, \( g \) is the determinant of the background Friedmann-Robertson-Walker metric, \( g^{\mu\nu} \). We allow also for a kinetic mixing through the function \( f_K(ϕ) \). We can write \( S \) in the Einstein frame (EF) as follows

\[
S = \int d^4x \sqrt{-\hat{g}} \left( -\frac{1}{2} m_p^2 \hat{R} + \frac{f_K(ϕ)}{2} \hat{g}^{\mu\nu} \partial_\mu \hat{\phi} \partial_\nu \hat{\phi} - \hat{V}_I(\hat{ϕ}) \right),
\]

(1.2)

by performing a conformal transformation [1] according to which we define the EF metric

\[
\hat{g}_{\mu\nu} = f_R(ϕ) g_{\mu\nu} \Rightarrow \begin{cases} \sqrt{-\hat{g}} = f_R(ϕ) \sqrt{-g} \text{ and } \hat{g}^{\mu\nu} = g^{\mu\nu}/f_R, \\ \hat{R} = (R + 3 \Box \ln f_R + 3 g^{\mu\nu} \partial_\mu \hat{\phi} \partial_\nu \hat{\phi}/2 f_R^2) / f_R, \end{cases}
\]

(1.3)

where \( \Box = (-g)^{-1/2} \partial_\mu (\sqrt{-g} \partial^\mu) \) and hat is used to denote quantities defined in the EF. We also introduce the EF canonically normalized field, \( \hat{ϕ} \), and potential, \( \hat{V}_I(\hat{ϕ}) \), defined as follows:

\[
\left( \frac{d \hat{ϕ}}{d \phi} \right)^2 = J^2 = \frac{f_K}{f_R} + \frac{3}{2} m_p^2 \left( \frac{f_R \phi}{f_K} \right)^2 \text{ and } \hat{V}(\hat{ϕ}) = \frac{V_I(\hat{ϕ})}{f_R(\hat{ϕ})^2}.
\]

(1.4)

For convenient choices of \( V_I(ϕ) \) and \( f_R(ϕ) \) we can obtain a sufficiently flat \( \hat{V}_I(\hat{ϕ}) \) which can support nMI. The analysis of nMI in the EF using the standard slow-roll approximation is equivalent with the analysis in JF. We have just to keep in mind the dependence of \( \hat{ϕ} \) on \( ϕ \).

1.2 Inflationary Observables – Constraints

Under the assumptions that (i) the curvature perturbation generated by ϕ is solely responsible for the observed one and (ii) nMI is followed in turn by a decaying-inflaton, radiation and matter domination, the parameters of nMI can be restricted by requiring that:
The effective theory describing nMI remains valid. This aim can be achieved if the ultraviolet cut-off scale $\Lambda_{\text{eff}}$ remains larger than the inflationary scale which is represented by $V_1(\phi_s)^{1/4}$ or, less restrictively, by the corresponding Hubble parameter, $H_{\text{ls}} = V_1(\phi_s)^{1/2}/\sqrt{3}m_p$, i.e.

\begin{align}
\text{(a) } V_1(\phi_s)^{1/4} &\leq \Lambda_{\text{eff}}, \quad \text{or (b) } H_{\text{ls}} &\leq \Lambda_{\text{eff}} \quad \text{with } \Lambda_{\text{eff}} \approx m_p/c_R.
\end{align}

Note that the imposition of Eq. (1.10) implies automatically the validity of $V_1(\phi_s)^{1/4} \leq m_p$ which is necessary in order to avoid possible corrections from quantum gravity. Less favored, from theoretical point of view, is also the domain of parameters where $\phi_s \geq m_p$. The conventions adopted for the description of the various restrictions on the parameters of our models are shown in Fig. 1.

(i) The number of e-foldings, $N_s$, that the scale $k_s = 0.05/\text{Mpc}$ suffers during nMI, leads to a solution of the horizon and flatness problems of standard big bang, i.e., [5]

\[ f \rho \frac{d\rho}{V_1(\phi_s)} = \int \phi \frac{d\phi}{V_1(\phi_s)} \approx 19.4 + 2\ln \left( \frac{V_1(\phi_s)^{1/4}}{1 \text{ GeV}} \right) - \frac{4}{3} \ln \left( \frac{V_1(\phi_s)^{1/4}}{1 \text{ GeV}} \right) + \frac{1}{3} \ln \left( \frac{m_R^2}{1 \text{ GeV}} \right) + \frac{1}{2} \ln \left( \frac{f_{R}(\phi_s)}{J(\phi_s)} \right). \]  

(1.5)

where $\phi_{\text{ls}}$ is the value of $\phi$ [\( \bar{\phi} \)] at the end of nMI, which can be found, in the slow-roll approximation and for the considered in this paper models, from the condition

\[ \max\{|\bar{\varepsilon}(\phi_s)|, |\bar{\eta}(\phi_s)|\} = 1, \]

where

\[ \bar{\varepsilon} = \frac{m_p^2}{2} \left( \frac{\tilde{V}_{1,\phi}}{V_1} \right)^2 = \frac{m_p^2}{2T_0^2} \left( \frac{\tilde{V}_{1,\phi}}{V_1} \right)^2 \quad \text{and} \quad \bar{\eta} = m_p^2 \left( \frac{\tilde{V}_{1,\phi}}{V_1} - \frac{\tilde{V}_{1,\phi}}{J_c} \right), \]

(1.6)

Also $T_{\text{hs}}$ is the reheat temperature after nMI, which is taken $T_{\text{hs}} = 10^8$ GeV throughout, since its variation over some orders of magnitude influences only weakly $N_s$, which remains close to 50.

(ii) The amplitude $A_s$ of the power spectrum of the curvature perturbation generated by $\phi$ at the pivot scale $k_s$ is consistent with data [5]

\[ \sqrt{A_s} = \frac{1}{2\sqrt{3} m_p^3} \left( \frac{\tilde{V}_{1,\phi}}{V_1} \right)^{3/2} \left( \frac{\tilde{V}_{1,\phi}}{V_1(\phi_s)} \right) \sim 4.685 \cdot 10^{-5}, \]

(1.7)

where $\phi_s [\bar{\phi}_s]$ is the value of $\phi [\bar{\phi}]$ when $k_s$ crosses outside the inflationary horizon.

(iii) The (scalar) spectral index, $n_s$, its running, $\alpha_s$, and the scalar-to-tensor ratio $r$ – estimated through the relations:

\[ n_s = 1 - 6\bar{\varepsilon}_s + 2\bar{\eta}_s, \quad \alpha_s = 2 \left( 4\bar{\eta}_s^2 - (n_s - 1)^2 \right) / 3 - 2\bar{\xi}_s, \quad \text{and} \quad r = 16\bar{\varepsilon}_s, \]

(1.8)

where $\bar{\xi} = m_p^2 \tilde{V}_{1,\phi} \bar{\eta}/\tilde{\nu}^2 = m_p^2 \tilde{V}_{1,\phi} \bar{\eta}/\tilde{V}_1 J^2 + 2\bar{\eta}\bar{\varepsilon}$ and the variables with subscript * are evaluated at $\phi = \phi_s$ – are consistent with the fitting of the data [5] with $\Lambda$CDM model, i.e.,

\[ (a) \quad n_s = 0.9603 \pm 0.0146, \quad (b) \quad -0.0314 \leq \alpha_s \leq 0.0046 \quad \text{and} \quad (c) \quad r < 0.11, \]

(1.9)

at 95% confidence level (c.l.)

(iv) The effective theory describing nMI remains valid. This aim can be achieved if the ultraviolet cut-off scale [6], $\Lambda_{\text{eff}}$, remains larger than the inflationary scale which is represented by $V_1(\phi_s)^{1/4}$ or, less restrictively, by the corresponding Hubble parameter, $H_{\text{ls}} = V_1(\phi_s)^{1/2}/\sqrt{3}m_p$, i.e.

\begin{align}
\text{(a) } V_1(\phi_s)^{1/4} &\leq \Lambda_{\text{eff}}, \quad \text{or (b) } H_{\text{ls}} &\leq \Lambda_{\text{eff}} \quad \text{with } \Lambda_{\text{eff}} \approx m_p/c_R.
\end{align}

(1.10)

Note that the imposition of Eq. (1.10) implies automatically the validity of $V_1(\phi_s)^{1/4} \leq m_p$ which is necessary in order to avoid possible corrections from quantum gravity. Less favored, from theoretical point of view, is also the domain of parameters where $\phi_s \geq m_p$. The conventions adopted for the description of the various restrictions on the parameters of our models are shown in Fig. 1.
1.3 Non-SUSY Models of nMI

Using the criteria of Sec. 1.2.1, it would be instructive to test two simple models of inflation based in quartic (Sec. 1.3.1) and quadratic (Sec. 1.3.2) potential using minimal and, conveniently, non-minimal coupling functions.

1.3.1 The Quartic Potential

Adopting the potential \( V_I = \lambda \phi^4 / 4 \) for the inflaton \( \phi \) we can analyze the cases:

(i) If we use \( f_R = 1 \) and \( f_K = 1 \), i.e., the minimal coupling to gravity, the slow-roll parameters and the number of e-foldings, suffered from \( k_s \), during minimal inflation (MI) can be calculated applying Eq. (\ref{eq:1}) and Eq. (\ref{eq:2}) – after removing hats and setting \( J = 1 \) – with results

\[
\epsilon \simeq 8m_p^2/\phi^2, \quad \eta \simeq 12m_p^2/\phi^2 \quad \text{and} \quad N_s \simeq \phi^2/8m_p^2. \tag{1.11a}
\]

Therefore, the values of \( \phi \) at the end of MI and the horizon crossing of \( k_s \) are transplanckian, since

\[
\phi_1 = 2\sqrt{3}m_p \quad \text{and} \quad \phi_s = 2\sqrt{2N_s}m_p. \tag{1.11b}
\]

Moreover, the normalization of Eq. (\ref{eq:3}) imposes the condition

\[
\sqrt{\mathcal{A}_s} \simeq \frac{\sqrt{\lambda} \phi^4}{16\sqrt{3}\pi m_p} = 4.685 \cdot 10^{-5} \Rightarrow \lambda^{1/2} \simeq \frac{3}{2} \cdot 4.685 \cdot 10^{-5} \pi N_s^{-3/2} \Rightarrow \lambda \simeq 2 \cdot 10^{-13} \tag{1.11c}
\]

for \( N_s \simeq 53 \). This value of \( \lambda \) signals an ugly tuning. From Eq. (\ref{eq:4}) we get

\[
n_s \simeq 1 - 3/N_s \simeq 0.947, \quad \alpha_s \simeq -3/N_s^2 \simeq 9.5 \cdot 10^{-4} \quad \text{and} \quad r \simeq 16/N_s \simeq 0.28, \tag{1.11d}
\]

with the last value being in clear contradiction with Eq. (\ref{eq:5}).

(ii) If we employ \( f_R(\phi) = 1 + c_R(\phi/m_p)^2 \) and \( f_K = 1 \), i.e., the standard non-minimal coupling to gravity, we find from Eq. (\ref{eq:6}), for \( c_R \gg 1 \)

\[
J \simeq \sqrt{6}m_p/\phi \quad \text{and} \quad \hat{V}_1 = \lambda \phi^4 / 4f_R^2 \simeq \lambda m_p^4 / 4c_R^2. \tag{1.12a}
\]

We observe that \( \hat{V}_1 \) exhibits an almost flat plateau. From Eqs. (\ref{eq:7}) and (\ref{eq:8}) we find

\[
\hat{\epsilon} \simeq 4m_p^4/3c_R^2\phi^4, \quad \hat{\eta} \simeq -4m_p^4/3c_R^2\phi^2 \quad \text{and} \quad \hat{N}_s \simeq 3c_R^2\phi^2 / 4m_p^2. \tag{1.12b}
\]

Therefore, \( \phi_1 \) and \( \phi_s \) are found from the condition of Eq. (\ref{eq:9}) and the last equality above, as follows

\[
\phi_1 = \sqrt[4]{4/3m_p} / \sqrt{c_R} \quad \text{and} \quad \phi_s = 2m_p/\sqrt{\hat{N}_s/3c_R}. \tag{1.12c}
\]

Also the normalization of Eq. (\ref{eq:10}) implies the following relation between \( c_R \) and \( \sqrt{\lambda} \)

\[
\sqrt{\mathcal{A}_s} \simeq \frac{\sqrt{\lambda}\hat{N}_s}{6\sqrt{2}\pi c_R} = 4.685 \cdot 10^{-5} \Rightarrow c_R \simeq 4.2 \cdot 10^4 \sqrt{\lambda} \tag{1.12d}
\]

for \( \hat{N}_s \simeq 52 \). Obviously \( \lambda \) can be larger than this in Eq. (\ref{eq:11}). From Eq. (\ref{eq:12}) we get

\[
n_s \simeq 1 - 2/\hat{N}_s \simeq 0.965, \quad \alpha_s \simeq -2/\hat{N}_s^2 \simeq -6.4 \cdot 10^{-4} \quad \text{and} \quad r \simeq 12/\hat{N}_s^2 \simeq 4 \cdot 10^{-3}, \tag{1.12e}
\]

which are in agreement with Eq. (\ref{eq:13}). If, in addition, we impose the requirement \( \phi \leq m_p \) and that of Eq. (\ref{eq:14}) we end-up with following ranges – c.f. Ref. [1]:

\[
74 \simeq 4\hat{N}/3 \lesssim c_R \lesssim 300 \quad \text{and} \quad 0.3 \lesssim \lambda / 10^{-5} \lesssim 4.6. \tag{1.12f}
\]

Therefore, the presence of \( f_R \) can rescue the model based on the simplest quartic potential.
\subsection*{1.3.2 The Quadratic Potential}

Focusing on the potential \( V_I = m^2 \phi^2 / 2 \) for the inflaton \( \phi \) we concentrate on the cases:

(i) If we use \( f_R = 1 \) and \( f_K = 1 \), i.e. the minimal coupling to gravity, and work along the lines of Sec.\[1.3.1\] from Eqs.\[i.1.2\] and \[i.1.5\] we find

\[ \epsilon = \eta = 2m_p^2 / \phi^2 \quad \text{and} \quad N_s = (\phi_i^2 - \phi_f^2) / 4m_p^2. \] \hspace{1cm} (1.13a)

Imposing the condition of Eq.\[i.1.6\] and solving the second expression above w.r.t \( \phi \), we find

\[ \phi_f = \sqrt{2m_p} \quad \text{and} \quad \phi_s \simeq 2m_p \sqrt{N_s}. \] \hspace{1cm} (1.13b)

As in Sec.\[1.3.1\] transplanckian \( \phi \)'s are required. Enforcing Eq.\[i.1.7\], we extract

\[ \sqrt{A_s} \simeq \frac{m\phi_i^2}{4\sqrt{6\pi m_p^2}} = 4.686 \cdot 10^{-5} \Rightarrow m \simeq 4.686 \cdot 10^{-5} \sqrt{6\pi m_p N_s^{-1}} \Rightarrow m \simeq 10^{13} \text{ GeV}, \] \hspace{1cm} (1.13c)

which can be related to the masses of the right-handed neutrinos \[2\]. Applying Eq.\[i.1.8\] we get

\[ n_s \simeq 1 - 2/N_s \simeq 0.965, \quad \alpha_s \simeq -2/N_s^2 \simeq -6.5 \cdot 10^{-4} \quad \text{and} \quad r \simeq 8/N_s \simeq 0.13. \] \hspace{1cm} (1.13d)

Although \( n_s \) is close to the observationally favored one, \( r \) is in tension with Eq.\[i.1.9\].

(ii) If we employ \( f_R(\phi) = 1 + c_R \phi / m_p \) and \( f_K = 1 \), i.e. a linear non-minimal coupling to gravity, we find from Eq.\[i.1.12\], for \( c_R \gg 1 \)

\[ J \simeq \sqrt{3/2m_p \phi^{-1}} \quad \text{and} \quad \tilde{V}_I \simeq m^2 \phi_i^2 / 2c_R^2, \] \hspace{1cm} (1.14a)

where a plateau is again generated as in Sec.\[1.3.1\]. Employing Eqs.\[i.1.5\], \[i.1.6\] and \[i.1.12\], the slow roll parameters and \( \tilde{N}_s \) read

\[ \tilde{\epsilon} \simeq 4m_p / 3c_R \phi^2, \quad \tilde{\eta} \simeq -4m_p / 3c_R \phi \quad \text{and} \quad \tilde{N}_s \simeq 3c_R \phi_s / 4m_p. \] \hspace{1cm} (1.14b)

Imposing the condition of Eq.\[i.1.13\] and solving then the latter equation w.r.t \( \phi \), we arrive at

\[ \phi_f \simeq 2m_p / \sqrt{3c_R} \quad \text{and} \quad \phi_s \simeq 4m_p \tilde{N}_s / 3c_R. \] \hspace{1cm} (1.14c)

On the other hand, Eq.\[i.1.7\] implies a relation between \( m \) and \( c_R \) – cf. Eq.\[i.1.2d\]

\[ \sqrt{A_s} \simeq \frac{m\tilde{N}_s}{6\pi m_p c_R} = 4.686 \cdot 10^{-5} \Rightarrow m = 4.13 \cdot 10^{13} c_R \text{ GeV}. \] \hspace{1cm} (1.14d)

Applying Eq.\[i.1.8\] we find that the predictions of the model w.r.t \( n_s, \alpha_s \) and \( r \) are identical to those in Eq.\[i.1.2d\]. If, in addition, we impose the requirement \( \phi \leq m_p \) and that of Eq.\[i.1.10a\] we end-up with following ranges – cf. Ref.\[1\]:

\[ 77 \simeq 4\tilde{N}_s / 3 \lesssim c_R \lesssim 313 \quad \text{and} \quad 2.9 \lesssim m / 10^{15} \text{ GeV} \lesssim 12, \] \hspace{1cm} (1.14e)

where the ranges above are derived numerically. Therefore, the presence of a linear \( f_R \) renders observationally more interesting the model based on the simplest quadratic potential.
1.4 Outline

It would be certainly interesting to enquire if it is possible to realize similar models of nMI in a SUSY framework where the hierarchy problem of Grand Unified Theories (GUTs) is elegantly resolved. We below describe the formulation of nMI in the context of Supergravity (SUGRA) and we specify three models of nMI: two with a gauge singlet inflaton (coupled to another gauge singlet in a linear-quadratic or a bilinear superpotential term) and one with a gauge non-singlet inflaton.

2. Realization of nMI Within SUGRA

In Sec. 2.1 we present the basic formulation of a theory which exhibits non-minimal coupling of scalar fields to $R$ within SUGRA and in Sec. 2.2 we outline our strategy in constructing viable models of nMI.

2.1 The General Set-up

Our starting point is the EF action for the scalar fields $\Phi^\alpha$ within SUGRA [2, 7] which can be written as

$$ S = \int d^4x \sqrt{-\bar{g}} \left(-\frac{1}{2}m^2_\Phi \bar{\Phi} + K_{\alpha}\bar{\Phi}^\alpha D_{\mu}\Phi^\alpha D^{\mu}\Phi^\alpha - \bar{V}\right), \quad (2.1a) $$

where the following notation is adopted

$$ K_{\alpha\dot{\alpha}} = K_{\Phi^\alpha \Phi^\dot{\alpha}} > 0 \quad \text{and} \quad D_{\mu}\Phi^\alpha = \partial_{\mu}\Phi^\alpha - A_{\mu}^A K_{\alpha}^\alpha $$

(2.1b)

are the covariant derivatives for scalar fields $\Phi^\alpha$. Here and henceforth the scalar components of the various superfields are denoted by the same superfield symbol. Also $A_{\mu}^A$ stand for the vector gauge fields and $k_{\alpha}^\alpha$ is the Killing vector, defining the gauge transformations of the scalars [7]. The EF potential, $\bar{V}$, is given in terms of the Kähler potential, $K$, and the superpotential, $W$, by

$$ \bar{V} = \bar{V}_F + \bar{V}_D \quad \text{with} \quad \bar{V}_F = e^{K/\mu} \left(K_{\alpha\dot{\alpha}} F_{\alpha} F_{\dot{\alpha}} - \frac{3}{2} |W|^2 m_\Phi^2 \right) \quad \text{and} \quad \bar{V}_D = 1/2 \bar{g}^2 \sum_{\alpha} D_{\mu} D_{\alpha}. \quad (2.1c) $$

Here, $g$ is the unified gauge coupling constant and the summation is applied over the generators $T_{\alpha}$ of a considered gauge group – a trivial gauge kinetic function is adopted. Also we use the shorthand

$$ K^{\alpha\beta} K_{\beta\gamma} = \delta_{\gamma}^\beta, \quad F_{\alpha} = W_{\Phi^\alpha} + K_{\Delta\alpha} W/m_\Phi^2 \quad \text{and} \quad D_{\alpha} = \Phi_{\alpha} (T_{\alpha})_\beta^\alpha K^{\beta} \quad \text{with} \quad K^\alpha = K_{\Phi^\alpha}. \quad (2.1d) $$

By performing a conformal transformation and adopting a frame function $\Omega$ which is related to $K$ as follows

$$ -\Omega/3 = e^{-K/3m_\Phi^2} \Rightarrow K = -3m_\Phi^2 \ln \left(-\Omega/3\right), \quad (2.2) $$

we arrive at the following action

$$ S = \int d^4x \sqrt{-\bar{g}} \left(-\frac{m_\Phi^2}{2} \left(-\frac{\Omega}{3}\right) R + m_\Phi^2 \Omega_{\alpha\dot{\alpha}} D_{\mu}\Phi^\alpha D^{\mu}\Phi^{\dot{\alpha}} - \omega_{\mu\nu} \omega^{\mu\nu} / m_\Phi^2 - V\right), \quad (2.3) $$

where $g_{\mu\nu} = -\left(3/\Omega\right) \delta_{\mu\nu}$ is the JF metric, we use the shorthand notation $\Omega_{\alpha} = \Omega_{\Phi^\alpha}$ and $\Omega_{\alpha} = \Omega_{\Phi^\alpha}$ and $\omega_{\mu}$ is the purely bosonic part of the on-shell value of the auxiliary field $A_{\mu}$ given by

$$ \omega_{\mu} = -im_\Phi^2 \left(D_{\mu}\Phi^\alpha \Omega_{\alpha} - D_{\mu}\Phi^{\dot{\alpha}} \Omega_{\dot{\alpha}}\right) / 2\Omega. \quad (2.4) $$
It is clear from Eq. (2.6) that $S$ exhibits non-minimal couplings of the $\Phi^\alpha$’s to $R$. However, $\Omega$ enters the kinetic terms of the $\Phi^\alpha$’s too. In general, $\Omega$ can be written as [7]

$$-\Omega/3 = 1 - F_K (\Phi^\alpha \Phi^*\alpha)/3 + (F_R (\Phi^\alpha) + F_R^* (\Phi^\alpha)),$$  

(2.5)

where $F_K$ is a dimensionless real function while $F_R$ is a dimensionless, holomorphic function. For $F_R > F_K$, $F_K$ expresses mainly the kinetic terms of the $\Phi^\alpha$’s whereas $F_R$ represents the non-minimal coupling to gravity – note that $\Omega_{\alpha\beta}$ is independent of $F_R$ since $F_{R,\alpha\beta\Phi^\beta} = 0$. In order to get canonical kinetic terms, we need [8] $\Omega_{\mu} = 0$ and $F_{K_{\alpha\beta}} \simeq \delta_{\alpha\beta}$. The first condition is attained when the dynamics of the $\Phi^\alpha$’s is dominated only by the real moduli $|\Phi^\alpha|$. The second condition is satisfied by the choice

$$F_K (|\Phi^\alpha|^2) = |\Phi^\alpha|^2/m_P^2 + k_{\alpha\beta} |\Phi^\alpha|^2 |\Phi^\beta|^2/m_P^4,$$  

(2.6)

with sufficiently small coefficients $k_{\alpha\beta}$. Here we assume that the $\Phi$’s are charged under a global – see Secs. 3 and 6 – or gauge – see Sec. 4 – $U(1)$ symmetry, so as mixed terms of the form $\Phi^\alpha \Phi^*\beta$ are disallowed. The inclusion of the fourth order term for the accompanying non-inflaton field, $\Phi^1 := S$ is obligatory in order to evade [7] a tachyonic instability occurring along this direction. As a consequence, all the allowed terms are to be considered in the analysis for consistency.

### 2.2 Modeling nMI in SUGRA

The realization of nMI in SUGRA requires $\hat\nabla^2 = 0$. This condition may be attained, when the inflaton is (the radial part of) a gauge:

- Singlet, by introducing an extra field $\Phi^2 := \Phi$ which obviously has zero contribution to $\hat\nabla^2$.
- Non-singlet by introducing a conjugate pair of Higgs superfields, $\Phi^2 := \Phi$ and $\Phi^3 := \bar{\Phi}$, which are parameterized so as $\hat{V}_D = 0$.

The presence of $S$ is crucial for the realization of our scenario, since it assists us to isolate via its derivative the contribution of the inflaton(s) in $\hat{V}$, Eq. (2.7). Indeed, placing $S$ at the origin the resulting $\hat{V} = \hat{V}_{10}$ – in both cases above – is equal to

$$\hat{V}_{10} = e^{K/m_P^2} K_{SS'} W_{SS'} W_{S'S} = V_F/f_{S\Phi} f_R^2$$

(2.7)

where $f_R = -\Omega/3$ and $f_{S\Phi} = m_P^2 \Omega_{SS'}$. Also $V_F = |W_{S'}|^2$ is the F-term SUSY potential, obtained from Eq. (2.7) with $D^2 = 0$ in the limit $m_P \to \infty$. Given that $f_{S\Phi} \ll f_R$, the construction of an inflationary plateau is reduced in the selection of the appropriate $W$ and $F_R$ so that $\hat{V}_{10} \simeq V_F/f_R^2$ is almost constant. In the case of a gauge-singlet inflaton, where $D^2 = 0$, this objective can be achieved with one of the two choices:

- If we set [2, 8] $W = \lambda S \Phi^2$ and $F_R = 1 + c_R \Phi^2/m_P^2$ – cf. Sec. 3.1, we obtain $V_F = \lambda^2 |\Phi|^4$ and $f_R^2 \simeq c_R^2 |\Phi|^2$ for $c_R \gg 1$. Therefore, Eq. (2.7) implies that $\hat{V}_{10}$ turns out to be almost constant.
- If we choose [4] $W = m S \Phi$ and $F_R = 1 + c_R \Phi/m_P$ – cf. Sec. 3.3, we find $V_F = m^2 |\Phi|^2$ and $f_R^2 \simeq c_R^2 |\Phi|^2$ for $c_R \gg 1$. Eq. (2.7) gives again an almost constant $\hat{V}_{10}$. 

7
In the case of a gauge non-singlet inflaton, we can take \[ W = \lambda \mathcal{S} (\Phi \Phi - M^2) \] which can be combined with the gauge invariant \( F_R, F_R = 1 + c_R \Phi \Phi / m_p^2 \) — cf. Ref. [9]. For \( |\Phi| = |\Phi| \), we expect \( V_b = 0, V_r \gtrsim \lambda^2 |\Phi|^4 \) (for \( \Phi > M \)) and \( f_R^2 \gtrsim c^2_R |\Phi|^4 \) for \( c_R > 1 \). Therefore, Eq. (2.7) again implies that \( \dot{V}_{10} \) is almost constant. The GUT gauge group is spontaneously broken during and at the end of nMI, where \( \Phi \) and \( \dot{\Phi} \) acquire their vacuum expectation values (VEVs) \( \langle \Phi \rangle = \langle \dot{\Phi} \rangle = M \) with SUSY unbroken — up to tiny corrections from SUSY breaking effects.

In the following we show details on the realization of these three scenarios. Our analysis is carried out exclusively in the EF substituting into Eq. (2.12), Eqs. (2.13) and (2.14) and the chosen \( F_R \). Then, Eq. (2.13) can be employed in order to find the canonically normalized inflaton field \( \hat{\phi} \) in terms of \( \phi \) defining
\[
f_K \hat{\phi}^2 / 2 = m_p^2 \Omega_{\alpha \beta} \hat{\phi}^a \hat{\phi}^\beta \quad \text{and} \quad f_R = -\Omega / 3.
\]
We also check the stability of the inflationary trajectory w.r.t the fluctuations of the non-inflaton fields and find the whole spectrum during nMI. Employing the derived masses we find the one-loop radiative correction \( \Delta V \) and the corresponding EF potential using the Coleman-Weinberg formula
\[
\dot{V}_I = \dot{V}_{10} + \Delta V \quad \text{with} \quad \Delta V = \frac{1}{64\pi^2} \sum_i (-)^4 m_i^4 \ln \frac{M_i^2}{\Lambda^2},
\]
where the sum extends over all helicity states \( i \), \( F_i \) and \( M_i^2 \) is the fermion number and mass squared of the \( i \)th state and \( \Lambda \) is a renormalization mass scale.

3. nMI with Quartic Potential for a Gauge Singlet Inflaton

This setting is realized in the presence of two superfields \( S \) and \( \Phi \) charged under a global \( U(1) \) symmetry with charges 2 and \( -1 \) respectively. In particular we take
\[
W = \lambda S \Phi^2, \quad F_R = \frac{c_\Phi}{4m_p^2} \Phi^2, \quad F_K = \frac{|S|^2}{m_p^2} + \frac{|\Phi|^2}{m_p^2} - 2k_S \frac{|S|^4}{m_p^4} - 2k_\Phi \frac{|\Phi|^4}{m_p^4} - 2k_{S\Phi} \frac{|S|^2 |\Phi|^2}{m_p^4}.
\]
In Sec. 3.1 we describe the salient features of this model and in Sec. 3.2 we expose our results.

3.1 Structure of the Inflationary Potential

The EF F–term (tree level) SUGRA scalar potential, \( \tilde{V} \), of this model is obtained from Eq. (2.15) upon substitution of Eq. (3.1) into Eqs. (2.13) and (2.14) with \( \Phi^1 := S \) and \( \Phi^2 := \Phi \) — note that \( D^a \Phi \) vanish by construction. We can verify that along the trajectory
\[
S = 0 \quad \text{and} \quad \theta := \arg \Phi = 0
\]
and for \( c_\Phi \gg 1 \), \( \tilde{V} \) develops a plateau with almost constant potential energy density, \( \tilde{V}_{10} \) and corresponding Hubble parameter \( \tilde{H}_I \) found by Eq. (2.7):
\[
\tilde{V}_{10} = \frac{\lambda^2 |\Phi|^4}{4f_{S\Phi} f_R^2} \simeq \frac{\lambda^2 m_p^4}{4f_{S\Phi} f_R^2} \quad \text{and} \quad \tilde{H}_I = \frac{\tilde{V}_{10}^{1/2}}{\sqrt{3} m_p} \simeq \frac{\lambda m_p}{2\sqrt{3} f_{S\Phi} c_R},
\]
where \( f_R \) and \( f_{S\Phi} \) are calculated by employing their definitions below Eq. (2.7)
\[
f_R = 1 + c_R x_\phi^2 + k_\Phi x_\phi^4 / 6 \quad \text{and} \quad f_{S\Phi} = 1 - k_{S\Phi} x_\phi^2 \quad \text{with} \quad x_\phi = \phi / m_p \quad \text{and} \quad c_R = c_\Phi / 4 - 1 / 6.
\]
From the relevant expressions above, the model depends on the following parameters: $\lambda$, $k_S$, $k_\Phi$, $k_{S\Phi}$, and $c_R$. Recalling that we use $T_m = 10^8$ GeV throughout. Our results are essentially independent of $k_S$, provided that $m_S^2 > 0$ for $\lambda < 1$ — see in Table I. We therefore set $k_S = 0.5$. Also we take a central value $k_\Phi = 0.5$. Besides these two values, in our numerical code, we use as input parameters $c_R$, $k_{S\Phi}$ and $\phi_s$. For every chosen $c_R \geq 1$, we restrict $\lambda$ and $\phi_s$ so that the
Figure 2: Allowed (hatched) region as determined by Eqs. (1.5), (1.7) and (1.9) in the $\lambda - c_R [\lambda - k_{SB}]$ plane (a) [(b)], for $k_S = k_B = 0.5$. The conventions adopted for the type and the color of the various lines are described in Fig. 1.

conditions Eqs. (13) and (14) are satisfied. By adjusting $k_{SB}$ we can achieve $n_s$’s in the range of Eq. (15). Our results are displayed in Fig. 2(a) [Fig. 2(b)], where we delineate the hatched region allowed by Eqs. (13), (15) and (19) in the $\lambda - c_R [\lambda - k_{SB}]$ plane. The conventions adopted for the various lines are shown in Fig. 3. In particular, the dashed [dot-dashed] lines correspond to $n_s = 0.975 [n_s = 0.946]$, whereas the solid lines are obtained by fixing $n_s = 0.96$ – see Eq. (17). The constraint of Eq. (19a) is satisfied along the various curves whereas Eq. (19a) is valid only along the gray and light gray segments of these. Along the light gray segments, though, we obtain $\phi_0 \geq m_p$. Note that for vanishing $k_{SB}$ and $k_B$ our results can be approximated by the analytical expressions exhibited in the paragraph (ii) of Sec. 3.3 replacing $\sqrt{\lambda}$ with $\lambda$. Indeed, $c_R$ remains almost proportional to $\lambda$ and for constant $\lambda$, $c_R$ increases as $n_s$ decreases. We remark that mostly negative $k_{SB}$’s are needed which for $\lambda > 0.16 \Leftrightarrow \phi_0 < 0.1m_p$ – see Eq. (26) – take quite natural (of order one) values. Focusing on $k_{SB} < 0$ for $n_s = 0.96$ and $N_\nu \simeq 50$ we find

$$112 \lesssim c_R \lesssim 1.6 \times 10^5 \mbox{ with } 2.5 \cdot 10^{-3} \lesssim \lambda \lesssim 3.7 \mbox{ and } 0 \lesssim -k_{SB} \lesssim 2.5 . \tag{3.8}$$

Also $6.8 \lesssim |\alpha_s|/10^{-4} \lesssim 8.2$ and $r \simeq 3.8 \cdot 10^{-3}$ which lie within the allowed ranges of Eq. (13).

4. nMI with Quartic Potential for a Gauge non-Singlet Inflaton

In the present scheme the inflaton field can be identified with the radial component of a conjugate pair of Higgs superfields. We here – cf. Ref. [9] – focus on the Higgs superfields, $\Phi$ and $\bar{\Phi}$, with $B - L = -1$, 1 which break a GUT symmetry, e.g., $G_{GUT} = G_{SM} \times U(1)_B - L$ down to MSSM gauge group $G_{SM}$ through their VEVs. We also impose a $U(1)$ $R$ symmetry, $U(1)_R$, which guarantees the linearity of the superpotential, $W$, w.r.t the singlet $S$ – see Table 2. The functions $W$, $F_R$

| SUPERFIELDS | $S$ | $\Phi$ | $\bar{\Phi}$ |
|-------------|-----|--------|-------------|
| $U(1)_{B-L}$ | 0   | 1      | -1          |
| $R$          | 1   | 0      | 0           |

Table 2: Charge assignments of the superfields.
and $F_K$, which respect the imposed symmetries, are respectively given by

$$\begin{align*}
W &= \lambda S (\Phi \Phi - M^2), \\
F_R &= \frac{c_{\Phi} \Phi \Phi}{2m_p}, \\
F_K &= \frac{\left| S \right|^2}{m_p} + \frac{\left| \Phi \right|^2}{m_p} + \frac{\left| \Phi \right|^2}{m_p} - k_b \Phi| \Phi|^4 m_p - k_b |\Phi|^4 m_p \tag{4.1a} \\
&- 2k_{\Phi \Phi} \Phi| \Phi|^2 m_p - 2k_{\Phi \Phi} |\Phi|^2 m_p - 2k_{\Phi \Phi} |\Phi|^2 m_p. \tag{4.1b}
\end{align*}$$

We below outline the salient features of our inflationary scenario (Sec. 4.1) and then, we present its predictions in Sec. 4.2.

### 4.1 Structure of the Inflationary Potential

The EF F-term (tree level) SUGRA scalar potential, $\hat{V}_{10}$, for this model is obtained by substituting Eqs. (4.1a) and (4.1b) into Eqs. (2.10) and (2.3) with $\Phi^1 = S$, $\Phi^2 = \Phi$ and $\Phi^3 = \bar{\Phi}$. If we parameterize the SM neutral fields $\Phi$ and $\bar{\Phi}$ by

$$\Phi = \phi e^{i\theta} \cos \theta_{\Phi}/\sqrt{2} \quad \text{and} \quad \bar{\Phi} = \phi e^{i\theta} \sin \theta_{\Phi}/\sqrt{2}, \tag{4.2}$$

we can easily deduce that a D-flat direction occurs at

$$\theta = \tilde{\theta} = 0 \quad \text{and} \quad \theta_{\Phi} = \pi/4, \tag{4.3}$$

provided that $K$ remains invariant under the interchange $\Phi \rightarrow \bar{\Phi}$ and $\bar{\Phi} \rightarrow \Phi$, which implies

$$k_{\Phi} = \tilde{k}_{\Phi} \quad \text{and} \quad k_{\Phi \Phi} = \tilde{k}_{\Phi \Phi}. \tag{4.4}$$

From Eq. (2.12), we can verify that for $c_R \gg 1$, $k_{\Phi \Phi} \ll 1$ and $m_{BL} \ll 1$, $\hat{V}$ takes a form suitable for the realization of nMI, since it develops a plateau. The (almost) constant potential energy density $\hat{V}_{10}$ and the corresponding Hubble parameter $\hat{H}_1$ – along the trajectory in Eq. (2.3) – are given by

$$\hat{V}_{10} = m_p^4 \frac{\lambda^2 (x_\phi^2 - 4m_B^2)^2}{16f_{\Phi \Phi} f_R} \simeq \frac{\lambda^2 m_p^2}{16f_{\Phi \Phi} c_R} \quad \text{and} \quad \hat{H}_1 = \frac{\hat{V}_{10}^{1/2}}{\sqrt{3} f_{\Phi \Phi} m_p} \simeq \frac{\lambda m_p}{4\sqrt{3} f_{\Phi \Phi} c_R}, \tag{4.5a}$$

where $f_R$ and $f_{\Phi \Phi}$, given by their definitions below Eq. (2.7), are specified as follows

$$f_R = 1 + c_R x_\phi^2 + (k_{\Phi} + k_{\Phi \Phi}) \frac{x_\phi^4}{24}, \quad f_{\Phi \Phi} = 1 - k_{\Phi \Phi} x_\phi^2 \quad \text{with} \quad m_{BL} = \frac{M}{m_p} \quad \text{and} \quad c_R = \frac{c_{\Phi \Phi}}{4} - \frac{1}{6}. \tag{4.5b}$$

We next proceed to check the stability of the trajectory in Eq. (2.3) w.r.t the fluctuations of $\theta_{\Phi}$, $\tilde{\theta}$, $\phi$ and $s/s/\sqrt{2}$ – here $S$ has been rotated to the real axis via a suitable R transformation. We first check that $\hat{V}_{\chi} = 0$, with $\chi = \theta_{\Phi}, \tilde{\theta}$ and $s$, and then we find

$$K_{\alpha \beta} \Phi^\alpha \Phi^\beta = \frac{1}{2} f_R (\hat{\Phi}^2 + \frac{1}{2} \hat{\theta}^2 \hat{\Phi}^2) + \frac{f_{R \Phi} \hat{\Phi}^2}{2f_R} \frac{1}{2} \frac{\hat{\Phi}^2 + \hat{\theta}^2}{2} + \frac{f_{R \Phi}}{2f_R} \hat{s}$$

$$= \frac{1}{2} \left( \hat{\Phi}^2 + \hat{\theta}^2 + \hat{\Phi}^2 + \hat{\theta}^2 \right) \quad \text{with} \quad \hat{\theta} = \frac{\hat{\Theta} + \hat{\Theta}}{\sqrt{2}} \quad \text{and} \quad s = \frac{S}{\sqrt{2}}. \tag{4.6}$$
In the last line, we introduce the EF canonically normalized fields, \(\hat{\theta}, \hat{\phi}, \hat{\theta}_+\), \(\hat{\theta}_-\) and \(\hat{s}\), defined as follows – cf. Ref. [3]:

\[
\frac{d\hat{\phi}}{d\phi} = J, \quad \hat{\theta}_+ = \frac{J\phi\theta_+}{\sqrt{2}}, \quad \hat{\theta}_- = \sqrt{\frac{f_{\phi}}{2f_R}}\phi\theta_-, \quad \hat{\phi}_{\pm} = \sqrt{\frac{f_{\phi}}{f_R}}\phi\left(\theta_{\pm} - \frac{\pi}{4}\right) \quad \text{and} \quad \hat{s} = \sqrt{\frac{f_{\phi}}{f_R}s}, \tag{4.7}
\]

where \(J\) and \(f_k\) can be found from Eqs. (1.24) and (2.8) with \(f_{\phi} = 1 - (k_{\phi} + k_{\phi^b})x_{\phi}^2\).

Having defined the canonically normalized scalar fields, we can derive the mass spectrum of the model along the direction of Eq. (4.3). Our results are listed in Table 3, where we present the eigenvalues and the corresponding eigenvectors of the relevant mass-squared matrices. As we observe, no instability arises in the spectrum, since \(k_S \geq 1\) ensures \(m_\Sigma^2 > 0\) and \(m_{\theta_0}^2 > 0\) thanks the D-term contributions which are proportional to \(g \simeq 0.7 > \lambda\). Moreover, the masses of the various scalars remain greater than \(\tilde{H}_I\) and so any perturbations of the fields other than the inflaton are safely eliminated. We also remark that \(U(1)_{B-L}\) is broken during nMI and therefore the gauge boson \(A_{BL}\) becomes massive absorbing the massless Goldstone boson associated with \(\hat{\theta}_-\). As a consequence, no cosmic strings are produced at the end of nMI and so, no extra restrictions on the parameters have to be imposed. From Table 3 we can deduce that the numbers of bosonic (8) and fermionic (8) d.o.f.s are equal. Plugging these results into Eq. (2.4) we get \(\Delta V\), which is dominated by the contributions from \(m_{\theta_0}^2\) and \(M_{BL}\), since these are proportional to \(g \gg \lambda\). Namely we find

\[
\Delta V \simeq \frac{1}{64\pi^2} \left( m_{\theta_0}^4 \ln\left( m_{\theta_0}^2 / \Lambda^2 \right) - M_{BL}^4 \ln( M_{BL}^2 / \Lambda^2 ) \right). \tag{4.8}
\]

Note that the presence of \(f_{\phi} \neq 1\) prevents the exact cancellation, occurring in Ref. [3], of the two contributions above. Since this result can be continued until the SUSY vacuum of the theory, we determine there the employed \(\Lambda\) by imposing the condition \(\Delta V = 0\).

### 4.2 Results

The free parameters of this model are \(\lambda, M, k_S, k_\phi, k_{\phi^b}, k_{\phi^b}, \) and \(c_R\). Following the same reasoning with Sec. [5] we set \(k_S = 1\) and \(k_\phi = 0.1\) throughout. Moreover, we can determine \(M\)
identifying the mass of the gauge boson $A_{BL}$ in the SUSY vacuum with the GUT scale $M_{GUT} \approx 2 \times 10^{16}$ GeV within the MSSM, i.e.

$$\sqrt{f_{\Phi 0}/f_{R0}} M = M_{GUT} \Rightarrow m_{BL} \simeq (2\sqrt{2c_{R}^{\text{max}} - c_{R}})^{-1} \text{ with } c_{R}^{\text{max}} = g^{2}m_{\Phi}^{2}/8M_{GUT}^{2},$$

(4.9)

$f_{R0} = f_{R}(x_{\Phi} = 2m_{BL})$ and $f_{\Phi 0} = f_{\Phi}(x_{\Phi} = 2m_{BL})$. The requirement $2c_{R}^{\text{max}} - c_{R} > 0$ sets an upper bound $c_{R} < 2c_{R}^{\text{max}} \approx 1.8 \times 10^{3}$. To obtain solutions consistent with the requirements of Sec. 4 we need a rather low $k_{\Phi}$. We take $k_{\Phi} = 0.01$.

Working along the lines of Sec. 3 we delimitate the allowed (hatched) region, as determined by Eqs. (1.5), (1.7) and (1.9) in the $\lambda - c_{R}$ [$\lambda - k_{S\Phi}$] plane – see Fig. 3(a) [Fig. 3(b)]. The conventions adopted for the various lines are shown in Fig. 1. We observe that the allowed region is considerably shrunk w.r.t that obtained with a gauge singlet inflaton in Fig. 2 and this is limited in the regime where only Eq. (1.9b) is valid. Also $c_{R}$ remains almost proportional to $\lambda$ and increases as $n_{s}$ decreases. Note that for vanishing $k'$s, our results can be approximated by the analytical expressions exhibited in the paragraph (ii) of Sec. 4 replacing $\sqrt{\lambda}$ with $\lambda/2$. Especially for $n_{s} = 0.96$ and $\tilde{N}_{s} \simeq 50$ we find

$$7.3 \lesssim c_{R}/10^{2} \lesssim 18 \text{ with } 2.9 \lesssim \lambda/10^{-2} \lesssim 8.4 \text{ and } 0.6 \lesssim -k_{S\Phi}/10^{-1} \lesssim 8.5.$$

(4.10)

Therefore, $k_{S\Phi} < 0$ assists us again to obtain the central $n_{s}$ in Eq. (3.3a). Also $0.7 \lesssim |\alpha_{s}|/10^{-3} \lesssim 1.2$ and $r \simeq (3 - 3.8) \cdot 10^{-3}$ in agreement with Eq. (3.4).

5. nMI with Quadratic Potential

This model [4] is characterized by the following ingredients:

$$W = mS\Phi, \quad F_{R} = \frac{c_{\Phi}}{\sqrt{2m_{\Phi}}}\Phi, \quad F_{K} = \frac{|S|^{2}}{m_{S}^{2}} + \frac{|\Phi|^{2}}{m_{\Phi}^{2}} - 2k_{S}\frac{|S|^{4}}{m_{S}^{4}} - 2k_{\Phi}\frac{|\Phi|^{4}}{m_{\Phi}^{4}} - 2k_{S}\frac{|S|^{2}|\Phi|^{2}}{m_{S}^{2}m_{\Phi}^{2}}.$$

To ensure the form of $W$ and $F_{K}$ we can impose a global $U(1)$ symmetry under which $S$ and $\Phi$ have charges 1 and $-1$. The imposed $U(1)$ is broken though during nMI by $F_{R}$. Due to the form of $F_{R}$, in which $\Phi$ appears linearly, $\Phi$ has to be singlet under the gauge group of the theory and therefore, we obtain $D\Phi = 0$ by construction. In Sec. 5.1 we outline the derivation of the inflationary potential of this model and in Sec. 5.2 we present our results.
Table 4: The mass spectrum of the model along the inflationary trajectory in Eq. (3.2).

5.1 Structure of the Inflationary Potential

Inserting Eq. (5.1) into Eqs. (5.3) and (5.4) we can derive $\hat{V}$ which, along the trajectory of Eq. (5.2) for $c_R \gg 1$ and $x_\phi \ll \sqrt{6}$, develops a plateau with (almost) constant potential energy density, $\hat{V}_{i0}$ and corresponding Hubble parameter $\hat{H}_i$ calculated, in accordance with Eq. (4.7), as

$$\hat{V}_{i0} = \frac{m^2\phi^2}{2f_{\Phi}} \approx \frac{m^2m_\phi^2}{2c_R^2f_{\Phi}}$$

and

$$\hat{H}_i = \frac{\hat{V}_{i0}^{\frac{1}{2}}}{\sqrt{3m_\phi}} \approx \frac{m}{\sqrt{6}f_{\Phi}c_R},$$

where $f_R$ and $f_{\Phi}$, defined below Eq. (4.7), are specified as follows

$$f_R = 1 + c_R x_\phi - x_\phi^2/6 + k_\Phi x_\phi^3/6 \text{ and } f_{\Phi} = 1 - k_{\Phi} x_\phi^2.$$  (5.2b)

To check the stability of the trajectory of Eq. (5.2) w.r.t the fluctuations of the various fields we expand $\Phi$ and $S$ in real and imaginary parts according to the prescription of Eq. (5.4). We then find that along the trajectory of Eq. (5.2), $K_{\alpha\beta}$ defined in Eq. (4.13) turns out to be

$$\begin{align*}
(K_{\alpha\beta}) &= \mathrm{diag}(J^2, f_{\Phi}/f_R) \quad \text{where} \quad J \simeq \sqrt{3}c_R/\sqrt{2}f_R \simeq \sqrt{3/2}x_\phi^{-1}. 
\end{align*}$$

Consequently, we can introduce the EF canonically normalized fields, $\hat{\phi}, \hat{\theta}$ and $\hat{\xi}_i$ with $i = 1, 2$ which satisfy Eq. (5.1) with the hatted fields defined as in Eq. (4.7). As in the previous cases, we check the stability of the inflationary path in Eq. (5.2) deriving the mass spectrum of the model, presented in Table 4. We observe that now the various masses are proportional to $m$ and obviously our findings are similar to those obtained in Sec. 5.1.

5.2 Results

This model depends on the parameters: $m$, $k_S$, $k_{\Phi}$, $k_{\Phi}$, and $c_R$. Following the same reasoning with Sec. 5.2 we set throughout $k_S = k_{\Phi} = 0.5$. The allowed (hatched) regions in the $m - c_R$ and $m - k_{\Phi}$ plane, as determined by Eqs. (1.6), (1.7) and (1.9), are depicted in Fig. 4-(a) and Fig. 4-(b) respectively, following the conventions Fig. 2. We confine conservatively ourselves to values $m \lesssim 3 \cdot 10^{17}$ GeV. For vanishing $k'$s, our results here are almost identical with those in paragraph (ii) of Sec. 4.3.2. For $m \gtrsim 4 \cdot 10^{16}$ GeV, rather natural $k_{\Phi}$'s result to $n_s = 0.96$. For this $n_s$, $\hat{N}_s \approx 50$ and confining ourselves to $k_{\Phi} < 0$ we find

$$1.2 \lesssim c_R/10^2 \lesssim 60 \text{ with } 0.5 \lesssim m/10^{16} \text{ GeV} \lesssim 3 \text{ and } 0 \lesssim -k_{\Phi} \lesssim 2.4. \quad (5.4)$$

Also $\alpha_\phi \sim -6.5 \cdot 10^{-4}$ and $r \sim 3.9 \cdot 10^{-3}$ compatibly with Eq. (1.14). Note, though, that for $k_{\Phi} > 0$ and $\phi > m_\phi$ we can obtain $\alpha_\phi$ and $r$ as large as 0.006 and 0.036 respectively.
6. Conclusions

We reviewed the implementation of nMI in both a non-SUSY and a SUSY framework, by conveniently choosing the coupling function of the inflaton to gravity. In all cases the inflationary observables are compatible with the current data. In the SUSY cases the tachyonic instability, occurring along the direction of the accompanying non-inflaton field, can be remedied by considering terms up to the fourth order in the kinetic part of the frame function. Some of these terms assist in obtaining $n_s$ close to its central observationally favored value. The role of the inflaton can be played by a gauge singlet or non-singlet superfield. In the latter case, though, a conjugation symmetry has to be imposed to the higher order terms so that the flatness of the potential is maintained and the radiative corrections turn out to be significant. For this reason, we can conclude that nMI within SUGRA is more naturally realized by a gauge singlet inflaton.
