Surface-Emitting Circular Bragg Lasers – A Promising Next-Generation On-Chip Light Source for Optical Communications

Xiankai Sun and Amnon Yariv

Department of Applied Physics, California Institute of Technology,
Pasadena, California 91125,
USA

1. Introduction

Surface-emitting lasers have been attracting people’s interest over the past two decades because of their salient features such as low-threshold current, single-mode operation, and wafer-scale integration (Iga, 2000). Their low-divergence surface-normal emission also facilitates output coupling and packaging. Although Vertical Cavity Surface Emitting Lasers (VCSELs) have already been commercially available, their single-modedness and good emission pattern are guaranteed only for devices with a small mode area (diameter of ~\( \mu \text{m} \)). Attempts of further increase in the emission aperture have failed mostly because of the contradictory requirements of large-area emitting aperture and single modedness, which casts a shadow over the usefulness of VCSELs in high-power applications.

A highly desirable semiconductor laser will consist of a large aperture (say, diameter larger than 20 \( \mu \text{m} \)) emitting vertically (i.e., perpendicularly to the plane of the laser). It should possess the high efficiency typical of current-pumped, edge-emitting semiconductor lasers and, crucially, be single-moded. Taking a clue from the traditional edge-emitting distributed feedback (DFB) semiconductor laser, we proposed employing transverse circular Bragg confinement mechanism to achieve the goals and those lasers are accordingly referred to as “circular Bragg lasers.”

There have been intensive research activities in planar circular grating lasers since early 1990s. Erdogan and Hall were the first to analyze their modal behavior with a coupled-mode theory (Erdogan & Hall, 1990, 1992). Wu et al. were the first to experimentally realize such lasers in semiconductors (Wu et al., 1991; Wu et al., 1992). With a more rigorous theoretical framework, Shams-Zadeh-Amiri et al. analyzed their above-threshold properties and radiation fields (Shams-Zadeh-Amiri et al., 2000, 2003). More recently, organic polymers are also used as the gain medium for these lasers due to their low fabrication cost (Jebali et al., 2004; Turnbull et al., 2005; Chen et al., 2007).

The circular gratings in the above-referenced work are designed radially periodic. In 2003 we proposed using Hankel-phased, i.e., radially chirped, gratings to achieve optimal interaction with the optical fields (Scheuer & Yariv, 2003), since the eigenmodes of the wave equation in cylindrical coordinates are Hankel functions. With their grating designed to follow the phases of Hankel functions, these circular Bragg lasers usually take three

configurations as shown in Fig. 1: (a) circular DFB laser, in which the grating extends from the center to the exterior boundary \(x_b\); (b) disk Bragg laser, in which a center disk is surrounded by a radial Bragg grating extending from \(x_0\) to \(x_b\); (c) ring Bragg laser, in which an annular defect is surrounded by both inner and outer gratings extending respectively from the center to \(x_L\) and from \(x_R\) to \(x_b\). Including a second-order Fourier component, the gratings are able to provide in-plane feedback as well as couple laser emission out of the resonator plane in vertical direction.

Fig. 1. Surface-emitting circular Bragg lasers: (a) circular DFB laser; (b) disk Bragg laser; (c) ring Bragg laser. Laser emission is coupled out of the resonator plane in vertical direction via the Bragg gratings.

This chapter will present a comprehensive and systematic study on the surface-emitting Hankel-phased circular Bragg lasers. It is structured in the following manner: Sec. 2 focuses on every aspect in solving the modes of the lasers – analytical method, numerical method, and mode-solving accuracy check. Sec. 3 gives near-threshold modal properties of the lasers; comparison of different types of lasers demonstrates the advantages of disk and ring Bragg lasers in high-efficiency surface laser emission. Sec. 4 discusses above-threshold modal behavior, nonuniform pumping effect, and optimal design for different types of lasers. Sec. 5 concludes this chapter and suggests directions for future research.

2. Mode solving techniques

Taking into account the resonant vertical laser radiation, Appendix A presents a derivation of a comprehensive coupled-mode theory for the Hankel-phased circular grating structures in active media. The effect of vertical radiation is incorporated into the coupled in-plane wave equations by a numerical Green’s function method. The in-plane (vertically confined) electric field is expressed as

\[
E(x) = A(x)H_{m}^{(1)}(x) + B(x)H_{m}^{(2)}(x),
\]

where \(H_{m}^{(1)}(x)\) and \(H_{m}^{(2)}(x)\) are the \(m\)th-order Hankel functions which represent respectively the in-plane outward and inward propagating cylindrical waves. A set of evolution equations for the amplitudes \(A(x)\) and \(B(x)\) is obtained:

\[
\frac{dA(x)}{dx} = u(x) \cdot A(x) - v(x) \cdot B(x) \cdot e^{2i\delta \cdot x},
\]

\[
\frac{dB(x)}{dx} = -u(x) \cdot B(x) + v(x) \cdot A(x) \cdot e^{-2i\delta \cdot x},
\]

where
\[ x = \beta \rho \] normalized radial coordinate with \( \beta \) being the in-plane propagation constant;
\[ \delta = (\beta_{\text{design}} - \beta) / \beta \] frequency detuning factor, representing a relative frequency shift of a resonant mode from the designed value;

\[ u(x) = \begin{cases} g_A(x) - h_1, & \text{if } x \text{ is within a grating region} \\ g_A(x), & \text{if } x \text{ is within a no-grating region} \end{cases} \]

\[ v(x) = \begin{cases} h_1 + ih_2, & \text{if } x \text{ is within a grating region} \\ 0, & \text{if } x \text{ is within a no-grating region} \end{cases} \]

\[ h_1 = h_{1r} + ih_{1i}: \text{grating's radiation coupling coefficient, representing the effect of vertical laser radiation on the in-plane modes;} \]
\[ h_2: \text{grating's feedback coupling coefficient, which can always be chosen real;} \]
\[ g_A(x) = g(x) - \alpha: \text{space-dependent net gain coefficient, the minimum value of which required to achieve laser emission will be solved analytically or numerically;} \]
\[ \alpha: \text{nonsaturable internal loss, including absorption and nonradiative scattering losses;} \]
\[ g(x) = g_0(x)/[1 + l(x)/I_{\text{sat}}]: \text{intensity-dependent saturated gain profile;} \]
\[ g_0(x): \text{unsaturated gain profile;} \]
\[ l(x)/I_{\text{sat}}: \text{field intensity distribution in units of saturation intensity.} \]

It should be noted that, although Eqs. (2) and (3) appear to be a set of coupled equations for in-plane waves only, they implicitly include the effect of vertical radiation due to \( h_1 \). As it will become clearer in Sec. 2.3, the vertical radiation can simply be treated as a loss term during the process of solving the in-plane laser modes.

### 2.1 Analytical mode solving method

When solving the modes at threshold with uniform gain (or pump) distribution across the device, the net gain coefficient \( g_A \) is \( x \) independent. The generic solutions of Eqs. (2) and (3) in no-grating regions are trivial:

\[ A(x) = A_0 e^{\delta x}, \]
\[ B(x) = B_0 e^{-\delta x}. \]

In grating regions, by introducing \( \tilde{A}(x) = A(x)e^{-i\delta x} \) and \( \tilde{B}(x) = B(x)e^{i\delta x} \), Eqs. (2) and (3) become:

\[ \frac{d\tilde{A}(x)}{dx} = (u - i\delta) \tilde{A}(x) - v \tilde{B}(x), \]
\[ \frac{d\tilde{B}(x)}{dx} = -(u - i\delta) \tilde{B}(x) + v \tilde{A}(x), \]

whose generic solutions lead to

\[ A(x) = A(0)e^{i\delta x} \frac{\sinh[S(x - L)] + C \cosh[S(x - L)]}{-\sinh[SL] + C \cosh[SL]}, \]
\[ B(x) = \frac{A(0)e^{-i\delta x}}{v} \cdot \frac{[(u-i\delta)-\mathbb{C}S]\sinh[S(x-L)]+[\mathbb{C}(u-i\delta)-S]\cosh[S(x-L)]}{-\sinh[SL]+\mathbb{C}\cosh[SL]} \]  

where \( S = \sqrt{(u-i\delta)^2-v^2} \), \( \mathbb{C} \) is a constant to be determined by specific boundary conditions, and \( L \) is a normalized length parameter (see Fig. 2). The determination of the constant \( \mathbb{C} \) in Eqs. (8) and (9) requires the specific boundary conditions be applied to the grating under investigation.

We focus on two typical boundary conditions to obtain \( \mathbb{C} \) and the corresponding field reflectivity in each case.

**Case I:** As shown in Fig. 2(a), the grating extends from the center \( x = 0 \) to \( x = L \). An inward propagating wave with amplitude \( B(L) \) impinges from outside on the grating. The reflectivity is defined as \( r_1(L) = A(L)/B(L) \). The finiteness of \( E(x) \) at the center \( x = 0 \) requires \( A(0) = B(0) \), leading to

\[ \mathbb{C} = \frac{(u-v-i\delta)\sinh[SL]+S\cosh[SL]}{S\sinh[SL]+(u-v-i\delta)\cosh[SL]} \]

and to the reflectivity

\[ r_1(L) = \frac{A(L)}{B(L)} = e^{2i\delta L} \frac{(u-v-i\delta)\sinh[SL]+S\cosh[SL]}{-(u-v-i\delta)\sinh[SL]+S\cosh[SL]} \]  \hspace{1cm} (10)

**Case II:** As shown in Fig. 2(b), the grating extends from \( x = x_0 \) to \( x = L \). An outward propagating wave with amplitude \( A(x_0) \) impinges from inside on the grating. The reflectivity is defined as \( r_2(x_0, L) = B(x_0)/A(x_0) \). No inward propagating wave comes from outside of the grating, i.e., \( B(L) = 0 \). This condition leads to \( \mathbb{C} = S/(u-i\delta) \) and to the reflectivity

\[ r_2(x_0, L) = \frac{B(x_0)}{A(x_0)} = e^{2i\delta x_0} \frac{v\sinh[S(L-x_0)]}{(u-i\delta)\sinh[S(L-x_0)]-S\cosh[S(L-x_0)]} \]  \hspace{1cm} (11)

It should be noted that, as seen from their definitions, the above reflectivities Eqs. (10) and (11) include the propagation phase.

With the obtained reflectivities for the two types of boundary conditions, it is easy to derive the laser threshold condition for each circular Bragg laser configuration.

1. **Circular DFB laser:**
   The limiting cases \( r_1(x_0) \rightarrow \infty \) or \( r_2(0, x_0) = 1 \) lead to the same result
Surface-Emitting Circular Bragg Lasers – A Promising Next-Generation On-Chip Light Source for Optical Communications

\[ \tanh[S_{b,0}] = \frac{S}{u - i\delta}. \]  

(12)

2. Disk Bragg laser:
Considering the radially propagating waves in the disk and taking the unity reflectivity at the center, the threshold condition is
\[ e^{2(g_A - i\delta)x_0} \cdot r_2(x_0, x_b) = 1, \]
which reads
\[ \frac{e^{2(g_A - i\delta)x_0} \cdot v \cdot \sinh[S(x_b - x_0)]}{(u - i\delta) \sinh[S(x_b - x_0)] - S \cosh[S(x_b - x_0)]} = 1. \]  

(13)

3. Ring Bragg laser:
Considering the radially propagating waves in the annular defect, the threshold condition is
\[ r_1(x_L) \cdot e^{2(g_A - i\delta)x_L} \cdot r_2(x_R, x_b) = 1, \]
which reads
\[ \frac{(u - v - i\delta) \sinh[S_{L,1}] + S \cosh[S_{L,1}]}{(u - v - i\delta) \sinh[S_{L,1}] + S \cosh[S_{L,1}]} \cdot \frac{e^{2(g_A - i\delta)(x_b - x_L)} \cdot v \cdot \sinh[S(x_b - x_R)]}{(u - i\delta) \sinh[S(x_b - x_R)] - S \cosh[S(x_b - x_R)]} = 1. \]  

(14)

The above threshold conditions Eqs. (12), (13), and (14) govern the modes of the lasers of each type and will be used to obtain their threshold gains \( g_A \) and corresponding detuning factors \( \delta \). With these values, substituting Eqs. (4), (5), (8), and (9) into Eq. (1) and then matching them at the interfaces yield the corresponding in-plane modal field patterns. Despite their much simpler and more direct forms, these threshold conditions automatically satisfy the requirements that \( E(x) \) and \( E'(x) \) be continuous at every interface between the grating and no-grating regions (Sun & Yariv, 2009c).

2.2 Numerical mode solving method
When solving the modes at threshold with uniform gain (or pump) distribution across the device, \( g_A \) is independent of \( x \) so that Eqs. (2) and (3) can have analytical solutions Eqs. (4) and (5), or (8) and (9). In the case of using a nonuniform pump profile and/or taking into account the gain saturation effect in above-threshold operation, \( g_A \) becomes dependent on \( x \) and Eqs. (2) and (3) have to be solved numerically. The modes are then obtained by identifying those satisfying the boundary conditions.

As explained in Sec. 2.1, the same boundary conditions (BCs) apply to all the three types of circular Bragg lasers: (i) \( A(0) = B(0) \); (ii) \( B(x_0) = 0 \); (iii) \( A(x) \) and \( B(x) \) continuous for \( 0 < x < x_0 \). In Eqs. (2) and (3), \( g_0(x) \) for a certain gain distribution profile can be parameterized with a proportionality constant, say, its maximal value \( g_0 \).

The mode solving procedure is as follows: Having BC(i), we start with an amplitude set \([A \; B] = A(0)[1 \; 1] \) at the center, then numerically integrate Eqs. (2) and (3) along \( x \) to the exterior boundary \( x_b \), during which both \( A \) and \( B \) values are kept continuous at every interface between grating and no-grating regions to satisfy BC(iii). After the integration, we have \( B(x_0) \) whose absolute value marks a contour map in the 2-D plane of \( g_0 \) and \( \delta \). Now each minimum point in this contour map satisfies BC(ii) and thus represents a mode with corresponding \( g_0 \) and \( \delta \). Retrieving \( A(x) \) and \( B(x) \) for this mode and substituting them into Eq. (1) give the modal field pattern.

We can also calculate the modal pump level using the obtained \( g_0 \). Assuming a linear pump–gain relationship above transparency, the unsaturated gain \( g_0(x) \) follows the profile of pump intensity \( I_{pump}(x) \), and we may define the pump level \( P_{pump} \equiv \int I_{pump}(x) \cdot 2\pi \rho \cdot d\rho = \)
\[ P_0 \int g_0(x) \cdot x \cdot dx, \text{ where } P_0 \text{ having a power unit is a proportionality constant determined by specific experimental setup. For simple } g_0(x) \text{ profiles, } P_{\text{pump}} \text{ can have analytical expressions as will be shown in Sec. 4.2, otherwise, numerical integration always remains a resort.} \]

### 2.3 Mode-solving accuracy check

In this subsection we derive an energy relation on which the examination of mode-solving accuracy is based. This energy relation is a direct result of the coupled-mode equations (2) and (3) combined with the boundary conditions and thus is exact. Similar to the procedure in (Haus, 1975), multiplying Eq. (2) by \( A^* \) and Eq. (3) by \( B^* \), then adding each equation to its complex conjugate, one obtains

\[
\frac{d|A|^2}{dx} = 2\left( g_A - h_{tr} \right) |A|^2 - v \cdot A^* B \cdot e^{2i\delta x} - v^* \cdot AB^* \cdot e^{-2i\delta x}, \tag{15}
\]

\[
\frac{d|B|^2}{dx} = -2\left( g_A - h_{tr} \right) |B|^2 + v \cdot A B^* \cdot e^{2i\delta x} + v^* \cdot A^* B \cdot e^{-2i\delta x}. \tag{16}
\]

Subtracting Eq. (16) from Eq. (15) yields

\[
\frac{d}{dx} \left( |A|^2 - |B|^2 \right) = 2g_A \left( |A|^2 + |B|^2 \right) - 2h_{tr} \left( A e^{-i\delta x} + B e^{i\delta x} \right)^2. \tag{17}
\]

Integrating Eq. (17) from \( x = 0 \) to \( x = x_b \) and applying the boundary conditions \( A(0) = B(0) \) and \( B(x_b) = 0 \) lead to

\[
\left[ A(x_b) \right]^2 + 2h_{tr} \int_{0}^{x_b} g_A \left( |A|^2 + |B|^2 \right) dx = 2 \int_{0}^{x_b} g_A \left( |A|^2 + |B|^2 \right) dx, \tag{18}
\]

which is interpreted as the energy conservation theorem for the surface-emitting circular Bragg lasers. This equation states that, in steady state, the net power generated in the gain medium is equal to the sum of peripheral leakage power and vertical emission power. Due to its exactness, we may use this relation to monitor the accuracy of mode solving by substituting into Eq. (18) the obtained modal \( g_0(x) \), \( \delta \), \( A(x) \), and \( B(x) \) and comparing the left-hand and right-hand sides of the equation.

As an aside, it should be noted that all the power terms in Eq. (18) are in units of a saturation power defined by

\[ P_{\text{sat}} \equiv E_{\text{sat}}^2 \cdot 4D / \beta, \tag{19} \]

where \( E_{\text{sat}} \) is the saturation field which relates to the saturation intensity by \( I_{\text{sat}} = cn_0 E_{\text{sat}}^2 / 2 \) (\( c \), the speed of light; \( n \), transverse effective index; \( \varepsilon_0 \), the vacuum permittivity), and \( D \) is the thickness (vertical dimension) of the laser resonator.

### 3. Near-threshold modal properties

#### 3.1 Threshold, frequency detuning, and in-plane modal pattern

For numerical demonstration, we assume all the lasers possess a vertical layer structure as described in (Scheuer et al., 2005a) which was designed for 1.55 \( \mu \text{m} \) laser emission. The
grating design procedure is detailed in Appendix B. The effective index $n_{\text{eff}}$ is calculated to be 2.83 and the in-plane propagation constant $\beta = k_0 n_{\text{eff}} = 11.47 \ \mu m^{-1}$. The circular grating is designed to follow the phase of Hankel functions with $m = 0$ to favor circularly symmetric modes. A quarter duty cycle is chosen to have both large feedback for in-plane waves while keeping a considerable amount of vertical emission. The coupling coefficients were found to be $h_1 = 0.0072 + 0.0108i$ and $h_2 = 0.0601$.

Since we would like to compare the modal properties of different types of lasers with the same footprint, a typical device size of $x_b = 200$ (corresponding to $\rho_b \approx 17.4 \ \mu m$) is assumed for all. For the disk Bragg laser, the inner disk radius $x_0$ is assumed to be $x_b/2 = 100$. For the ring Bragg laser, the annular defect is assumed to be located at the middle $x_b/2 = 100$ and the defect width is set to be a wavelength of the cylindrical waves therein, yielding $x_L + x_R = x_b = 200$ and $x_R - x_L = 2\pi$. The calculated modal field patterns, along with the corresponding threshold gain values ($g_A$) and frequency detuning factors ($\delta$), of the circular DFB, disk, and ring Bragg lasers are listed in Table 1.

| Mode number | 1 | 2 | 3 | 4 | 5 |
|-------------|---|---|---|---|---|
| Circular DFB laser | Modal field | ![Modal Field 1](image1) | ![Modal Field 2](image2) | ![Modal Field 3](image3) | ![Modal Field 4](image4) | ![Modal Field 5](image5) |
| $g_A (10^{-3})$ | 0.283 | 1.03 | 2.04 | 3.11 | 4.12 |
| $\delta (10^{-3})$ | 61.8 | 66.6 | 74.1 | 83.6 | 94.6 |
| Disk Bragg laser | Modal field | ![Modal Field 1](image1) | ![Modal Field 2](image2) | ![Modal Field 3](image3) | ![Modal Field 4](image4) | ![Modal Field 5](image5) |
| $g_A (10^{-3})$ | 0.127 | 0.288 | 0.454 | 0.690 | 1.21 |
| $\delta (10^{-3})$ | 49.8 | 21.2 | -8.09 | -37.4 | -66.5 |
| Ring Bragg laser | Modal field | ![Modal Field 1](image1) | ![Modal Field 2](image2) | ![Modal Field 3](image3) | ![Modal Field 4](image4) | ![Modal Field 5](image5) |
| $g_A (10^{-3})$ | 0.457 | 1.06 | 1.92 | 3.14 | 4.09 |
| $\delta (10^{-3})$ | 55.9 | 66.9 | 71.0 | 84.4 | 91.6 |

Table 1. Modal field patterns, along with their threshold gains ($g_A$) and frequency detuning factors ($\delta$), of the circular DFB, disk, and ring Bragg lasers. All the three types of lasers have an exterior boundary radius of $x_b = 200$. After (Sun & Yariv, 2008)

A comparison of these modal properties concludes the following features of the three laser structures:

1. All the displayed modes of the circular DFB laser are in-band modes on one side of the band gap (all $\delta > 0$). This is due to the radiation coupling induced mode selection mechanism (Sun & Yariv, 2007). Increased gain results in the excitation of higher-order modes.

2. All the displayed modes of the disk Bragg laser are confined to the center disk with negligible peripheral power leakage and thus possess very low thresholds and very small modal volumes as will be shown in Sec. 3.3.
3. All the displayed modes of the ring Bragg laser, with the exception of the fundamental defect mode, resemble their counterparts of the circular DFB laser. The defect mode has a larger threshold gain than the fundamental mode of the circular DFB laser, but the former possesses a much higher emission efficiency as will be shown in Sec. 3.3.

3.2 Radiation field and far-field pattern

As mentioned earlier, by implementing a second-order circular grating design, the gratings can not only provide feedback for the in-plane fields but also couple the laser emission vertically out of the resonator plane. As derived in Appendix A, Eq. (A12) relates the in-plane fields with the vertical radiation field in the grating regions. The radiation pattern at the emission surface is known as the near-field. For the grating design with \( m = 0 \), the near-field is expressed as

\[
\Delta E = \left( s_1 A e^{-i\delta x} + s_{-1} B e^{i\delta x} \right) |H_0^{(1)}|, \tag{20}
\]

where \( s_1 \) and \( s_{-1} \) at the emission surface can be obtained numerically according to Eq. (A13) for a given grating structure. Following the design procedure in Appendix B, both \( s_1 \) and \( s_{-1} \) at the emission surface were calculated to be 0.1725 \(-0.0969i\). Using the Huygens–Fresnel principle, the diffracted far-field radiation pattern of light from a circular aperture can be calculated under the parallel ray approximation (\(|r| \gg |r'|\)) (Hecht, 1998):

\[
U(r) \propto \int \int_{\text{aperture}} \Delta E(\rho, \varphi) \exp\left(i k |r - r'| \right) \rho \epsilon r' \\frac{4 \pi}{r'} \div \int \int_{\text{aperture}} \Delta E(\rho, \varphi) \exp\left(-i k (r' \cdot \hat{r}) \right) \rho \epsilon r' \\div \left(21\right)
\]

where \( \rho \epsilon r' = \rho \cos \varphi \hat{x} + \rho \sin \varphi \hat{y} \)

is the source point and

\( r = r \sin \theta \cos \phi \hat{x} + r \sin \theta \sin \phi \hat{y} + r \cos \theta \hat{z} \)

is the field point. The far-field intensity pattern is then given by

\[
I(r) = U^*(r) U(r) = |U(r)|^2 \tag{22}
\]

and plotted in Fig. 3 for the fundamental mode of circular DFB, disk, and ring Bragg lasers.

In the far-field patterns, the different lobes correspond to different diffraction orders of the light emitted from the circular aperture. In the circular DFB and ring Bragg lasers, most of the energy is located in the first-order Fourier component thus their first-order diffraction peaks dominate. In the disk Bragg laser it is obvious that the zeroth-order peak dominates. These calculation results are similar to some of the experimental data for circular DFB and DBR lasers (Fallahi et al., 1994; Jordan et al., 1997).
3.3 Single-mode range, quality factor, modal area, and internal emission efficiency

In the previous subsections we have compared the modal properties for devices with a fixed exterior boundary radius \( x_b = 200 \). In what follows we will vary the device size and investigate the size dependence of modal gains to determine the single-mode range for each laser type. Within each own single-mode range limit, the fundamental mode of these lasers will be used to calculate and compare the quality factor, modal area, and internal emission efficiency. Similar to the prior calculations with a fixed \( x_b \), we still keep \( x_0 = x_b/2 \) for the disk Bragg laser and \( x_L + x_R = x_b \), \( x_R - x_L = 2\pi \) for the ring Bragg laser even as \( x_b \) varies.

**Single-Mode Range**

In the circular Bragg lasers, since a longer radial Bragg grating can provide stronger feedback for in-plane waves, larger devices usually require a lower threshold gain. The downside is that a larger size also results in smaller modal discrimination, which is unfavorable for single-mode operation in these lasers. As a result, there exists a range of the exterior boundary radius \( x_b \) values for each laser type within which range the single-mode operation can be achieved. This range is referred to as the “single-mode range.” Figure 4 plots the evolution of threshold gains for the 5 lowest-order modes as \( x_b \) varies from 50 to 350. The single-mode ranges for the circular DFB, disk, and ring Bragg lasers are 50–250, 60–140, and 50–250, respectively, which are marked as the pink regions. Since single-mode
operation is usually preferred in laser designs, in the rest of this subsection we will limit $x_b$ to remain within each single-mode range and focus on the fundamental mode only.

**Quality Factor**

As a measure of the speed with which a resonator dissipates its energy, the quality factor $Q$ for optical resonators is usually defined as $\omega \mathcal{E} / P$ where $\omega$ denotes the radian resonance frequency, $\mathcal{E}$ the total energy stored in the resonator, and $P$ the power loss. In our surface-emitting circular Bragg lasers, the power loss $P$ has two contributions: coherent vertical laser emission coupled out of the resonator due to the first-order Bragg diffraction, and peripheral power leakage due to the finite radial length of the Bragg reflector.

Jebali et al. recently developed an analytical formalism to calculate the $Q$ factor for first-order circular grating resonators using a 2-D model in which the in-plane peripheral leakage was considered as the only source of power loss (Jebali et al., 2007). To include the vertical emission as another source of the power loss, a rigorous analytical derivation of the $Q$ factor requires a 3-D model be established. This is much more complicated than the 2-D case. However, since we are interested in comparing different laser types, a relative $Q$ value will be good enough.

Considering that the energy stored in a volume is proportional to $\int |E|^2 \, dV$ and that the outflow power through a surface is proportional to $\int |E|^2 \, dS$, we define an unnormalized quality factor

$$Q' = \frac{\int_0^D dz \int_0^{2\pi} d\varphi \int_0^{r_b} |E(\rho, z)|^2 \rho d\rho}{\iint_{\text{grating}} \Delta E(\rho, z = 0)^2 \rho d\rho d\varphi + \int_0^D dz \int_0^{2\pi} |E(\rho = r_b, z)|^2 \rho_b d\varphi}$$

$$= \frac{\int_0^D Z^2(z) \, dz \int_0^{x_b} |E(x)|^2 \, dx}{\int_{\text{grating}} \Delta E(x, z = 0)^2 \, dx + \int_0^D Z^2(z) \, dz \cdot |E(x = x_b)|^2 \, \beta x_b},$$

where $Z(z)$ denotes the vertical mode profile for a given layer structure [see Eq. (A3)] and $D$ the thickness of the laser resonator. For a circularly symmetric mode, the angular integration factors are canceled out. The expressions for the in-plane field $E$ and radiation field $\Delta E$ are given by Eqs. (1) and (20), respectively.

The unnormalized quality factor $Q'$ Eq. (23) is obviously proportional to an exact $Q$ and the former is more intuitive and convenient for calculational purposes. The $Q'$ of the fundamental mode for the three laser types is calculated and displayed in Fig. 5. As expected, increase in the device size ($x_b$) results in an enhanced $Q'$ value for all three types of lasers. Additionally, the disk Bragg laser exhibits a much higher $Q'$ than the other two laser structures of identical dimensions. As an example, for $x_b = 100$, the $Q'$ value of the disk Bragg laser is approximately 3 times greater than that of the circular DFB or ring Bragg lasers. This is consistent with their threshold behaviors shown in Table 1.

**Modal Area**

Based on the definition of modal volume (Coccioli et al., 1998), an effective modal area is similarly defined:

$$A_{\text{mode}}^{\text{eff}} = \frac{\iint |E|^2 \, x dx d\varphi}{\max \{|E|^2\}}.$$
Fig. 5. Unnormalized quality factor of circular DFB, disk, and ring Bragg lasers. After (Sun & Yariv, 2008)

The modal area is a measure of how the modal field is distributed within the resonator. A highly localized mode having a small modal area can have strong interaction with the emitter. Figure 6 plots $A_{\text{mode}}^{\text{eff}}$ of the fundamental mode, within each single-mode range, for the three laser types. The top surface area of the laser resonator ($\pi x_b^2$) is also plotted to serve as a reference. The modal area of the disk Bragg laser is found to be at least one order of magnitude lower than those of the circular DFB and ring Bragg lasers. This is not surprising and can be inferred from their unique modal profiles listed in Table 1.

Fig. 6. Modal area of circular DFB, disk, and ring Bragg lasers. The top surface area of the laser resonator ($\pi x_b^2$) is also plotted as a reference. After (Sun & Yariv, 2008)

Internal Emission Efficiency

As mentioned earlier, the generated net power in the circular Bragg lasers is dissipated by two kinds of loss: vertical laser emission and peripheral power leakage. The internal emission efficiency $\eta_{\text{in}}$ is thus naturally defined as the fraction of the total power loss which is represented by the useful vertical laser emission. Figure 7 depicts the $\eta_{\text{in}}$ of the fundamental mode, within each single-mode range, for the three laser types. As expected,
all the lasers possess a larger \( \eta \) in with a larger device size. Comparing devices of identical dimensions, only the disk and ring Bragg lasers achieve high emission efficiencies. This is a result of their fundamental modes being located in a band gap while the circular DFB laser’s fundamental mode is at a band edge, i.e., in a band. Band-gap modes experience much stronger reflection from the Bragg gratings, yielding less peripheral power leakage than in-band modes.

Fig. 7. Internal emission efficiency of circular DFB, disk, and ring Bragg lasers. After (Sun & Yariv, 2008)

Summary of Comparison

In this subsection, by varying the device size we have obtained the single-mode range and compared the quality factor, modal area, and internal emission efficiency of the three types of lasers. It is demonstrated that, under similar conditions, disk Bragg laser has the highest quality factor, the smallest modal area, and the highest internal emission efficiency, indicating its suitability in high-efficiency, low-threshold, ultracompact laser design, while ring Bragg laser has a large single-mode range, large modal area, and high internal emission efficiency, indicating its wide application as a high-efficiency, large-area laser.

4. Above-threshold modal analysis

In Sec. 3 we have solved the modes and compared the near-threshold modal properties of the three types of surface-emitting circular Bragg lasers. This section focuses on an above-threshold modal analysis which includes gain saturation effect. The coupled-mode equations (2) and (3) will be solved numerically with boundary conditions. The relation of surface emission power versus pump power will be simulated. The laser threshold and external emission efficiency will be compared for these lasers under different pump profiles. Lastly, with the device size varying in a large range, the evolution curve of pump level for several lowest-order modes will be generated and the optimal design guidelines for these lasers will be suggested.

4.1 Surface emission power versus pump power relation

The numerical mode solving recipe is described in detail in Sec. 2.2. Simply put, Eqs. (2) and (3) are integrated along \( x \) from \( x = 0 \) to \( x = x_b \) with the initial boundary condition \( [A \ B] = \)
By identifying those satisfying the final boundary condition \( B(x_b) = 0 \) one finds the modes with corresponding \( g_0 \) and \( \delta \). The modal pump level is then given by \( P_{pump} = \int g_0(x) \cdot x \cdot dx \) in units of a proportionality constant \( P_0 \). Explained in Sec. 2.3, the surface emission power \( P_{em} \) from the laser is just the second term on the left-hand side of Eq. (18). By varying the value of \( A(0) \) at the beginning of the integration process, we are able to get the \((P_{pump}, P_{em})\) pairs which basically form the typical input–output relation for a laser mode.

As an example, we consider the circular DFB laser with \( x_b = 200 \) and the other structural parameters the same as those used in Sec. 3. The additional parameter used in the numerical integration, the nonsaturable internal loss \( \alpha \), is assumed to be \( 0.2 \times 10^{-3} \) (already normalized by \( \beta \)) for typical III–V quantum well lasers. With the simulated \((P_{pump}, P_{em})\) pairs, the typical laser input–output relation is obtained for the fundamental mode and plotted in Fig. 8. The laser threshold \( P_{th} \) is defined as the pump level at the onset of surface laser emission. The external emission efficiency (or, energy conversion efficiency) \( \eta_{ex} \) is defined as the slope \( dP_{em}/dP_{pump} \) of the linear fit of the simulated data points up to \( P_{em} = 10P_{sat} \). As can be seen, the output power varies linearly with the pump power above threshold, which is in agreement with the theoretical and experimental results for typical laser systems [see, e.g., Sec. 9.3 of (Yariv, 1989)].

![Fig. 8. Surface emission power \( P_{em} \) (in units of \( P_{sat} \)) versus pump power level \( P_{pump} \) for the fundamental mode of circular DFB laser (\( x_b = 200 \)) under uniform pumping. The laser threshold \( P_{th} \) is defined as the pump level at the onset of surface laser emission. The external emission efficiency \( \eta_{ex} \) is defined as the slope of the linear fit of the simulated data points up to \( P_{em} = 10P_{sat} \).]

4.2 Nonuniform pumping effects

So far our studies on the circular Bragg lasers have assumed a uniform pumping profile and thus a uniform gain distribution across the devices. In practical situations, the pumping profile is usually nonuniform, distributed either in a Gaussian shape in optical pumping (Olson et al., 1998; Scheuer et al., 2005a) or in an annular shape in electrical pumping (Wu et al., 1994). The effects of nonuniform pumping have been investigated theoretically (Kasunic et al., 1995; Greene & Hall, 2001) and experimentally (Turnbull et al., 2005) for circular DFB lasers. In this subsection we will study and compare the nonuniform effects on the three types of surface-emitting circular Bragg lasers.
Let us focus on three typical pumping profiles – uniform, Gaussian, and annular – as shown in Fig. 9. The pump level $P_{\text{pump}}$ can be expressed analytically in terms of the pump profile parameters:

a. Uniform:

$$g_0(x) = g_0, \quad 0 \leq x \leq x_p, \quad P_{\text{pump}} = \int_0^{x_b} g_0 \cdot x \cdot dx = \frac{1}{2} g_0 x_b^2,$$

(b) Gaussian:

$$g_0(x) = g_0 \exp\left(-\frac{x^2}{w_p^2}\right), \quad x \geq 0, \quad P_{\text{pump}} = \int_0^{\infty} g_0 \exp\left(-\frac{x^2}{w_p^2}\right) \cdot x \cdot dx = \frac{1}{2} g_0 w_p^2,$$

(c) Annular:

$$g_0(x) = g_0 \left[ \exp\left(-\frac{(x-x_p)^2}{w_p^2}\right) + \exp\left(-\frac{(x+x_p)^2}{w_p^2}\right) \right], \quad x \geq 0,$$

$$P_{\text{pump}} = \int_0^{\infty} g_0 \left[ \exp\left(-\frac{(x-x_p)^2}{w_p^2}\right) + \exp\left(-\frac{(x+x_p)^2}{w_p^2}\right) \right] \cdot x \cdot dx = g_0 w_p^2 \exp\left(-\frac{x_p^2}{w_p^2}\right) + \sqrt{\pi} w_p x_p \text{erf}\left(\frac{x_p}{w_p}\right),$$

where the error function $\text{erf}(x) \equiv \frac{2}{\sqrt{\pi}} \int_0^{x} \exp(-t^2) \, dt$.

To compare the nonuniform pumping effects, the typical exterior boundary radius $x_b = 200$ is again assumed for all the circular DFB, disk, and ring Bragg lasers. In addition, for the disk Bragg laser the inner disk radius is set to be $x_0 = x_b/2$, and for the ring Bragg laser the two interfaces separating the grating and no-grating regions are located at $x_L = x_b/2 - \pi$ and $x_R = x_b/2 + \pi$. Following the calculation procedure in Sec. 4.1, the threshold pump level $P_{\text{th}}$ and the external emission efficiency $\eta_{\text{ex}}$ of the fundamental mode of the three types of lasers were calculated with the uniform, Gaussian, and annular pump profiles, respectively, and the results are listed in Table 2. Without loss of generality, the Gaussian profile was assumed to follow Eq. (26) with $w_p = x_b/2 = 100$, and the annular profile was assumed to follow Eq. (27) with $x_p = x_b/2 = 100$ and $w_p = x_b/4 = 50$. The numbers shown in Table 2 indicate an inverse relation between $P_{\text{th}}$ and $\eta_{\text{ex}}$. The lowest $P_{\text{th}}$ and the highest $\eta_{\text{ex}}$ are achieved with the Gaussian pump for the circular DFB and disk Bragg lasers and with the annular pump for the ring Bragg laser.

These observations can actually be understood with fundamental laser physics: In any laser system the overlap factor between the gain spatial distribution and that of the modal intensity is crucial and proportionate. In semiconductor lasers once the pump power is strong enough to induce the population inversion the medium starts to amplify light. The lasing threshold is determined by equating the modal loss with the modal gain, which is the...
Table 2. Threshold pump level $P_{\text{th}}$ (in units of $P_0$) and external emission efficiency $\eta_{\text{ex}}$ (in units of $P_{\text{sat}}/P_0$) of circular DFB, disk, and ring Bragg lasers under different pump profiles. After (Sun & Yariv, 2009b)

| Pump profile | Circular DFB laser | Disk Bragg laser | Ring Bragg laser |
|--------------|--------------------|-----------------|-----------------|
|              | $P_{\text{th}}$    | $\eta_{\text{ex}}$ | $P_{\text{th}}$    | $\eta_{\text{ex}}$ | $P_{\text{th}}$    | $\eta_{\text{ex}}$ |
| Uniform      | 9.760              | 0.7369          | 6.565           | 0.4374           | 13.162           | 0.9278          |
| Gaussian     | 5.967              | 0.9961          | 2.373           | 0.8741           | 8.570            | 1.379           |
| Annular      | 6.382              | 0.9742          | 5.855           | 0.7358           | 7.010            | 1.500           |

Exponential gain constant experienced by the laser mode. This modal gain is proportional to the overlap integral between the spatial distribution of the gain and that of the modal intensity. Therefore if one assumes that, to the first order, the gain is proportional to the excess pump power over the transparency, then the threshold pump level $P_{\text{th}}$ is inversely proportional to the above overlap integral [see, e.g., Sec. 11.3 of (Yariv, 1989)]. On the other hand, since the rate of simulated emission per electron and thus the gain are proportional to the modal intensity as seen by the electron [see, e.g., Sec. 8.3 of (Yariv, 1989)], this leads to a direct proportion between the external emission efficiency $\eta_{\text{ex}}$ and the overlap integral. The bottom line is that a larger overlap between the pump profile and the modal intensity distribution results in more efficient energy conversion in the gain medium which consequently leads to a lower $P_{\text{th}}$ and a higher $\eta_{\text{ex}}$.

### 4.3 Considerations in optimal design

To obtain the optimal design for these circular Bragg lasers, we will again vary their device size in a large range and inspect their size-dependent behavior. Like what we have done in Sec. 3.3, we will vary the exterior boundary radius $x_b$ for all the lasers while keeping $x_0 = x_b/2$ for the disk Bragg laser and $x_L = x_b/2 - \pi$, $x_R = x_b/2 + \pi$ for the ring Bragg laser.

Figure 10 shows the dependence of the pump level $P_{\text{pump}}$ and the frequency detuning factor $\delta$ on the device size $x_b$ for the 3 lowest-order modes, under uniform pump profile, of the three types of lasers. In each subfigure, the modes are numbered in accord with those shown in Table 1. For both $P_{\text{pump}}$ and $\delta$, dashed lines mark their values obtained at threshold and solid lines at $P_{\text{em}} = 10P_{\text{sat}}$.

Seen from the upper left and right subplots of Fig. 10, the circular DFB and ring Bragg lasers still possess large discrimination between the modes even when operated in above-threshold regime (e.g., at $P_{\text{em}} = 10P_{\text{sat}}$), which ensures them a large single-mode range of at least 50–250. Additionally, we have identified low-pump ranges for their Mode 1 at $P_{\text{em}} = 10P_{\text{sat}}$, which are 100–160 for the circular DFB laser and 80–130 for the ring Bragg laser. The low-pump range is another important factor in designing such lasers for high-efficiency, high-power applications. The existence of this low-pump range is a result of competition between the pumped area and the required gain level: although larger devices require a larger area to be pumped, their longer radial Bragg gratings reduce the needed gain because of stronger reflection of the optical fields from the gratings.

Seen from the upper middle subplot of Fig. 10, the $P_{\text{pump}}$ for the disk Bragg laser exhibits interesting behaviors: (i) at $x_b = 200$, the order of Modes 1 and 2 exchanges from at threshold to above threshold due to the gain saturation effects; (ii) the single-mode range (for Mode 2) shifts from 60–140 at threshold to 90–175 at high surface emission level $P_{\text{em}} = 10P_{\text{sat}}$. Therefore the single-mode range for designing the disk Bragg laser should be the overlap of these two ranges, i.e., 90–140.
Fig. 10. Device-size-dependent pump level $P_{pump}$ and frequency detuning factor $\delta$ of the 3 lowest-order modes, under uniform pump profile, of (a) circular DFB, (b) disk, and (c) ring Bragg lasers. $x_b$ is the exterior boundary radius for all types of lasers. The inner disk radius $x_0$ of the disk Bragg laser is set to be $x_b/2$. The inner and outer edges of the annular defect of the ring Bragg laser are set to be $x_L = x_b/2 - \pi$ and $x_R = x_b/2 + \pi$, respectively. The modes are labeled in accord with those shown in Table 1. Dashed lines mark the values obtained at threshold and solid lines at $P_{em} = 10P_{sat}$. After (Sun & Yariv, 2009b)

Seen from the lower subplots of Fig. 10, all the laser modes have overlapped dashed and solid lines, which means their frequency detuning factors $\delta$ are unaffected by the surface emission level. This is because of $\delta$ being an intrinsic property of a laser mode.

5. Conclusion and outlook

In this chapter we have described and analyzed a type of on-chip microlasers whose surface emission is very useful for many applications. The main advantage of these lasers would be the relative high (say, more than tens of mW), single-mode optical power emitted broadside and coupled directly into a fiber or telescopic optics. Other areas of applications that can benefit from such lasers include ultrasensitive biochemical sensing (Scheuer et al., 2005b), all-optical gyroscopes (Scheuer, 2007), and coherent beam combination (Brauch et al., 2000) for high-power, high-radiance sources in communications and display technology. Furthermore, a thorough investigation of such lasers may also lead to a better understanding in designing and fabricating a nanosized analogue, if a surface-plasmon approach is employed.

Throughout this work we have been trying to make a small contribution to understanding of the circular Bragg lasers for their applications as high-efficiency, high-power, surface-emitting lasers. We have covered the basic concepts, calculation methods, near- and above-threshold modal properties, and design strategies for such lasers.
We have studied three typical configurations of such circular Bragg lasers – namely, circular DFB laser, disk Bragg laser, and ring Bragg laser. Following the grating design principle for linear DFB lasers, the gratings of circular Bragg lasers have to be in sync with the phases of optical waves in a circular (or cylindrical) geometry. Since the eigensolutions of wave equation in a circular geometry are Hankel functions, this leads to a varying period of the gratings in radial direction, i.e., radially chirped gratings. To obtain efficient output coupling in vertical direction, a second-order scheme has been employed, and a quarter duty cycle has proved to be a good choice.

After a series of comparison of the modal properties, it becomes clear that disk and ring Bragg lasers have superiority over circular DFB lasers in high-efficiency surface emission. More specifically, disk Bragg lasers are most useful in low-threshold, ultracompact laser design while ring Bragg lasers are excellent candidates for high-power, large-area lasers.

Considering above-threshold operation with a nonuniform pump profile, it has been numerically demonstrated and theoretically explained that a larger overlap between the pump profile and modal intensity distribution leads to a lower threshold and a higher energy conversion efficiency. To achieve the same level of surface emission, disk Bragg laser still requires the lowest pump power, even though its single-mode range is modified because of the gain saturation induced mode transition. Circular DFB and ring Bragg lasers find their low-pump ranges at high surface emission level. These results provide us useful information for designing these lasers for single-mode, high-efficiency, high-power applications.

Looking ahead, there is still more work to be done on this special topic. For example, it would be interesting to further investigate how the grating design effects on the modal far-field pattern and what design results in a pattern having all, or almost all, of the energy located in the zeroth-order lobe with narrow divergence. This will be useful for applications which require highly-directional, narrow-divergence laser beams. On the other hand, since this chapter is mainly theoretical analysis oriented, experimental work, of course, has to develop to verify the theoretical predictions. In the field of optoelectronics, a single-mode, high-power laser having controllable beam shape and compatible with on-chip integration is still being highly sought. Due to the many salient features that have been described, it is our belief that the surface-emitting circular Bragg lasers will take the place of the prevailing VCSELs and make the ideal on-chip light source for next-generation optical communications and many other areas.

Appendix A: Derivation of comprehensive coupled-mode theory for circular grating structure in an active medium

In the case that the polarization effects due to the waveguide structure are not concerned, we can start from the scalar Helmholtz equation for the $z$ component of electric field in cylindrical coordinates

$$
\left[\frac{1}{\rho} \frac{\partial}{\partial \rho} \left( \rho \frac{\partial}{\partial \rho} \right) + \frac{1}{\rho^2} \frac{\partial^2}{\partial \phi^2} + k_0^2 n^2 (\rho, z) + \frac{\partial^2}{\partial z^2} \right] E_z (\rho, \phi, z) = 0,
$$

(A1)

where $\rho$, $\phi$, and $z$ are respectively radial, azimuthal, and vertical coordinates, $k_0 = \omega/c = 2\pi/\lambda_0$ is the wave number in vacuum.
For an azimuthally propagating eigenmode, \( E_z \) in a passive uniform medium in which the dielectric constant \( \varepsilon_r(\rho, z) = \varepsilon_i(z) \) can be expressed as

\[
E_z(\rho, \varphi, z) = E_z^{(m)}(\rho, z) \exp(i m \varphi) = \left[ AH_m^{(1)}(\beta \rho) + BH_m^{(2)}(\beta \rho) \right] Z(z) \exp(i m \varphi),
\]

with \( m \) the azimuthal mode number, \( \beta = k_0 n_{\text{eff}} \) the in-plane propagation constant, and \( Z(z) \) the fundamental mode profile of the planar slab waveguide satisfying

\[
\left( k_0^2 \varepsilon_r(z) + \frac{\partial^2}{\partial z^2} \right) Z(z) = \beta^2 Z(z).
\]

In a radially perturbed gain medium, the dielectric constant can be expressed as \( n^2(\rho, z) = \varepsilon_i(z) + i \varepsilon(z) + \Delta \varepsilon(\rho, z) \) where \( \varepsilon_i(z) \) with \( | \varepsilon(z) | \ll \varepsilon_i(z) \) represents the medium gain or loss and \( \Delta \varepsilon(\rho, z) \) is the perturbation profile which in a cylindrical geometry can be expanded in Hankel-phased plane wave series:

\[
\Delta \varepsilon(\rho, z) = -\Delta \varepsilon_0 \sum_{l=1,2} a_I(z) \exp(-i l \Phi[H_m^{(1)}(\beta_{\text{design}} \rho)])
\]

\[
= -\Delta \varepsilon_0 \sum_{l=1,2} a_I(z) \exp(-i l \Phi[H_m^{(1)}(x)]) \exp(-i l \delta \cdot x)
\]

\[
= -\Delta \varepsilon_0 \left[ a_2(z) \frac{H_m^{(2)}}{H_m^{(1)}} e^{-2i \delta x} + a_{-2}(z) \frac{H_m^{(1)}}{H_m^{(2)}} e^{2i \delta x} + a_1(z) \frac{H_m^{(2)}}{H_m^{(1)}} e^{-i \delta x} + a_{-1}(z) \frac{H_m^{(1)}}{H_m^{(2)}} e^{i \delta x} \right].
\]

In the above expression, \( a_I(z) \) is the \( l \)th-order expansion coefficient of \( \Delta \varepsilon(\rho, z) \) at a given \( z \). \( x \) is the normalized radial coordinate defined as \( x = \beta \rho / \delta \). \( \delta = (\beta_{\text{design}} - \beta) / \beta \) (\( | \delta | \ll 1 \)), the normalized frequency detuning factor, represents a relative frequency shift of a resonant mode from the designed value.

To account for the vertical radiation, an additional term \( \Delta E(x, z) \) is introduced into the modal field so that

\[
E_z^{(m)}(x, z) = \left[ A(x) H_m^{(1)}(x) + B(x) H_m^{(2)}(x) \right] Z(z) + \Delta E(x, z).
\]

Assuming that the radiation field \( \Delta E(x, z) \) has an \( \exp(\pm ik_0 z) \) dependence on \( z \) in free space, i.e.,

\[
\left[ \frac{1}{\rho} \frac{\partial}{\partial \rho} \left( \rho \frac{\partial}{\partial \rho} \right) - \frac{m^2}{\rho^2} \right] \Delta E = 0,
\]

substituting Eqs. (A4), (A5), and (A6) into Eq. (A1), introducing the large-radius approximations (Scheuer & Yariv, 2003)

\[
\left| \frac{H_m^{(1,2)}(x)}{x} \right| \ll \left| \frac{d H_m^{(1,2)}(x)}{dx} \right|, \quad \frac{d^n H_m^{(1,2)}(x)}{dx^n} \approx (\pm i)^n H_m^{(1,2)}(x),
\]

neglecting the second derivatives of \( A(x) \) and \( B(x) \), and applying the modal solution in the passive unperturbed case, one obtains
The phase-matching condition requires that the source and wave have close phase dependence. Grouping the terms with the same kind of Hankel functions leads to the following set of coupled equations:

$$\begin{align*}
2i \frac{dA}{dx} H_m^{(1)} + i \frac{k_0^2 \epsilon_r}{\beta^2} H_m^{(1)} + \frac{1}{\beta^2} \left( k_0^2 \epsilon_r + i k_0^2 \epsilon_i + \frac{\partial^2}{\partial z^2} \right) \Delta E &= \frac{k_0 \Delta \epsilon_0}{\beta^2} \left[ a_2 H_m^{(2)} e^{-2i \delta_x} + a_2 H_m^{(2)} e^{2i \delta_x} + a_1 H_m^{(2)} e^{-i \delta_x} + a_1 H_m^{(2)} e^{i \delta_x} \right] \\
\times \left( A H_m^{(1)} + B H_m^{(2)} + \Delta E \right).
\end{align*}$$

(A8)

From Eq. (A11), $\Delta E$ can be expressed as

$$\Delta E = \left( s_1 A e^{-i \delta_x} + s_2 B e^{i \delta_x} \right) |H_m^{(1)}|,$$

(A12)

where

$$s_1(z) = k_0^2 \Delta \epsilon_0 \int_{-\infty}^{+\infty} a_1(z') G(z, z') dz',$$

(A13)

and $G(z, z')$ is the Green’s function satisfying

$$\left( k_0^2 \epsilon_r(z) + \frac{\partial^2}{\partial z^2} \right) G(z, z') = \delta(z - z').$$

(A14)

Substituting Eq. (A12) into Eqs. (A9) and (A10), multiplying both sides by $Z(z)$, and integrating over $z$ yield

$$\begin{align*}
\frac{dA}{dx} &= (g_{A} - h_{-1,1}) A - (h_{-1,-1} + ih_{-1,1}) B e^{2i \delta_x}, \\
\frac{dB}{dx} &= -(g_{A} - h_{-1,1}) B + (h_{-1,1} + ih_{-1,1}) A e^{-2i \delta_x},
\end{align*}$$

(A15)

(A16)

where the gain coefficient

$$g_{A} = -\frac{k_0^2}{2 P \beta^2} \int_{-\infty}^{+\infty} \epsilon_i(z) Z^2(z) dz.$$

(A17)
the radiation coupling coefficients

$$h_{1,1} = \frac{ik_0^2 \Delta \varepsilon_0}{2P \beta^2} \int_{-\infty}^{+\infty} a_{1,1}(z) s_{1,1}(z) Z(z) \, dz,$$

(A18)

the feedback coupling coefficients

$$h_{2,2} = \frac{k_0^2 \Delta \varepsilon_0}{2P \beta^2} \int_{-\infty}^{+\infty} a_{2,2}(z) Z^2(z) \, dz,$$

(A19)

and the normalization constant

$$P \equiv \int_{-\infty}^{+\infty} Z^2(z) \, dz.$$

(A20)

In the case of an index grating, we can choose the phase of the grating such that $a_{-1} = a_1$, $a_{-2} = a_2$, then we denote $h_1 = h_{2,1}$, $z_1 = h_2 = h_{2,2}$. By defining $u = g_A - h_1$ and $v = h_1 + ih_2$, Eqs. (A15) and (A16) become

$$\frac{dA(x)}{dx} = u(x) \cdot A(x) - v(x) \cdot B(x) \cdot e^{2i\delta x},$$

(A21)

$$\frac{dB(x)}{dx} = -u(x) \cdot B(x) + v(x) \cdot A(x) \cdot e^{-2i\delta x}.$$  

(A22)

Specifically, in the unperturbed (i.e., no-grating) region where $\Delta \varepsilon = 0$, $h_1$ and $h_2$ vanish, and Eqs. (A21) and (A22) reduce to

$$\frac{dA(x)}{dx} = g_{A,1}(x) \cdot A(x),$$

(A23)

$$\frac{dB(x)}{dx} = -g_{A,1}(x) \cdot B(x).$$

(A24)

Appendix B: Grating design procedure and calculations of the numerical Green’s function $G(z, z')$, coefficients $h_1$, $h_2$, and $s_1$

Since we have previously fabricated such Hankel-phased circular Bragg lasers in InGaAsP active semiconductor material (Scheuer et al., 2005a), we will use the layer structure therein as an example for our numerical study. The target lasing wavelength $\lambda_0$ is 1.55 $\mu$m. For simplicity, we approximate the complicated layer structure by an effective index profile comprising five layers as illustrated in Table B1. The vertical mode profile $Z(z)$ and the effective index $n_{\text{eff}}$ can be obtained numerically using a 1-D mode solver. The effective index $n_{\text{eff}}$ was calculated to be 2.83 and the in-plane propagation constant $\beta = k_0 n_{\text{eff}} = 11.47 \, \mu$m$^{-1}$. Numerical calculations of the mode profile and effective index of the approximated layer structure indicate negligible deviations from those of the exact one.

We focus our analysis on the case of a partially etched grating with an etch depth of 185 nm. The numerical Green’s function $G(z, z')$ that satisfies Eq. (A14) with the given layer structure was calculated for $-\infty < z < \infty$ and $z'$ between the top and bottom surfaces of the laser resonator. A surface plot of the real part of $G(z, z')$ is displayed in Fig. B1.
Table B1. Approximated layer structure for numerical study

| Layer description       | Refractive index $n$ | Thickness  |
|-------------------------|----------------------|------------|
| Upper cladding          | 1.54                 | $\infty$   |
| Third layer             | 3.281                | 60.5 nm    |
| Second layer (active region) | 3.4057               | 129 nm     |
| First layer             | 3.281                | 60.5 nm    |
| Lower cladding          | 1.54                 | $\infty$   |

To favor a circularly symmetric laser mode, $m = 0$ is specially chosen in the grating phase design. In such case, a Hankel-phased grating modulation with rectangular profile

$$\Theta(\Phi[H^{(l)}_{m}(x)], \alpha) = \begin{cases} 1, & \cos(\Phi[H^{(l)}_{m}(x)]) \geq \alpha \\ 0, & \cos(\Phi[H^{(l)}_{m}(x)]) < \alpha \end{cases}$$

(B1)

can be expanded in Fourier series as

$$\arccos \frac{\alpha}{\pi} + \frac{2}{\pi} \sum_{l=1}^{\infty} \sin(l \arccos \alpha) \frac{\cos(l \Phi[H^{(l)}_{m}(x)])}{l} = \arccos \frac{\alpha}{\pi} + \frac{2}{\pi} \left[ \sin(\arccos \alpha) \cos(\Phi[H^{(1)}_{m}(x)]) + \frac{\sin(2 \arccos \alpha)}{2} \cos(2 \Phi[H^{(1)}_{m}(x)]) + \cdots \right]$$

(B2)

$$= d_c + \frac{1}{2\pi} \sin(2\pi d_c) \left[ \exp(-i2\Phi[H^{(1)}_{m}(x)]) + \exp(i2\Phi[H^{(1)}_{m}(x)]) \right]$$

$$+ \frac{1}{\pi} \sin(\pi d_c) \left[ \exp(-i\Phi[H^{(1)}_{m}(x)]) + \exp(i\Phi[H^{(1)}_{m}(x)]) \right] + \cdots.$$  

The expansion yields the coefficients

$$a_2 = a_{-2} = \frac{\sin(2\pi d_c)}{2\pi}$$

and
\[ a_i = a_{-1} = \frac{\sin(\pi d_c)}{\pi} \]

where

\[ d_c \equiv \frac{\text{arccos} \alpha}{\pi} \quad (-1 < \alpha < 1, \quad 0 < d_c < 1) \]

is the duty cycle of the Hankel-phased rectangular grating. It should be emphasized that the duty cycle has a significant role in determining the coupling coefficients \( h_1 \) and \( h_2 \) (Barlow et al., 2004). Figure B2 plots \( h_1 \) and \( h_2 \) as a function of the duty cycle \( d_c \). A judicious choice would be \( d_c = 0.25 \) where \( h_2 \) is maximal and Re\((h_1)\) is not small so that we can have a large ratio of vertical emission to power leakage, hence a high emission efficiency. Based on Eqs. (A18) and (A19), the grating’s coupling coefficients were found to be \( h_1 = 0.0072 + 0.0108i \) and \( h_2 = 0.0601 \). Calculated from Eq. (A13), \( s_1 \) and \( s_{-1} \) at the emission surface (i.e., the top surface of the laser resonator) were found to be \( 0.1725 - 0.0969i \).

Fig. B2. Radiation coupling coefficient \( h_1 \) and feedback coupling coefficient \( h_2 \) as a function of the duty cycle \( d_c \) of the Hankel-phased rectangular grating. After (Sun et al., 2007)

As the editor, I feel extremely happy to present to the readers such a rich collection of chapters authored/co-authored by a large number of experts from around the world covering the broad field of guided wave optics and optoelectronics. Most of the chapters are state-of-the-art on respective topics or areas that are emerging. Several authors narrated technological challenges in a lucid manner, which was possible because of individual expertise of the authors in their own subject specialties. I have no doubt that this book will be useful to graduate students, teachers, researchers, and practicing engineers and technologists and that they would love to have it on their book shelves for ready reference at any time.
