SHIFTED YANGIANS AND FINITE W-ALGEBRAS

JONATHAN BRUNDAN AND ALEXANDER KLESHCHEV

Abstract. We give a presentation for the finite W-algebra associated to a nilpotent matrix in the general linear Lie algebra over \( \mathbb{C} \). In the special case that the nilpotent matrix consists of \( n \) Jordan blocks each of the same size \( l \), the presentation is that of the Yangian of level \( l \) associated to \( \mathfrak{gl}_n \), as was first observed by Ragoucy and Sorba. In the general case, we are lead to introduce some generalizations of the Yangian which we call the shifted Yangians.

1. Introduction

Let \( \mathfrak{g} \) be a finite dimensional reductive Lie algebra over \( \mathbb{C} \) equipped with a non-degenerate invariant symmetric bilinear form \( (.,.) \). Pick a nilpotent element \( e \in \mathfrak{g} \), i.e. an element which acts nilpotently on every finite dimensional \( \mathfrak{g} \)-module. A \( \mathbb{Z} \)-grading \( \mathfrak{g} = \bigoplus_{j \in \mathbb{Z}} \mathfrak{g}_j \) of \( \mathfrak{g} \) is called a good grading for \( e \) if \( e \in \mathfrak{g}_2 \) and the linear map \( \text{ad} \ e : \mathfrak{g}_j \to \mathfrak{g}_{j+2} \) is injective for \( j \leq -1 \), surjective for \( j \geq -1 \). This definition originates in \( [KRW] \) in the study of certain W-algebras defined from affine Lie algebras by quantum Hamiltonian reduction. A complete classification of all good gradings of simple Lie algebras up to conjugacy can be found in \( [EK] \).

Since \( \text{ad} \ e : \mathfrak{g}_{-1} \to \mathfrak{g}_1 \) is bijective, the skew-symmetric bilinear form \( \langle ., . \rangle \) on \( \mathfrak{g}_{-1} \) defined by \( \langle x, y \rangle := ([x, y], e) \) is non-degenerate. Pick a Lagrangian subspace \( l \) of \( \mathfrak{g}_{-1} \) with respect to the form \( \langle ., . \rangle \) and set \( \mathfrak{m} := l \oplus \bigoplus_{j \leq -2} \mathfrak{g}_j \). This is a nilpotent subalgebra of \( \mathfrak{g} \), and the map \( \chi : \mathfrak{m} \to \mathbb{C}, \ x \mapsto \langle x, e \rangle \) defines a representation of \( \mathfrak{m} \). Let \( I_\chi \) denote the kernel of the corresponding associative algebra homomorphism \( U(\mathfrak{m}) \to \mathbb{C} \), where \( U(\mathfrak{m}) \) denotes the universal enveloping algebra of \( \mathfrak{m} \). Let

\[
\mathfrak{g}_j := U(\mathfrak{g}) \otimes_{U(\mathfrak{m})} \mathbb{C}_\chi \cong U(\mathfrak{g})/U(\mathfrak{g})I_\chi
\]

denote the induced \( \mathfrak{g} \)-module, and consider the endomorphism algebra

\[
W(\chi) := \text{End}_{U(\mathfrak{g})}(Q_\chi)^{op}.
\]

Following terminology used in the mathematical physics literature, we refer to these algebras as finite W-algebras; see e.g. \( [BT] \). Applying Frobenius reciprocity, it is often more convenient to view \( W(\chi) \) instead as the subspace of \( U(\mathfrak{g})/U(\mathfrak{g})I_\chi \) consisting of all cosets \( y + U(\mathfrak{g})I_\chi \) such that \( [x, y] \in U(\mathfrak{g})I_\chi \) for all \( x \in \mathfrak{m} \). In this realization, the algebra structure on \( W(\chi) \) is defined by the formula \( (y + U(\mathfrak{g})I_\chi)(y' + U(\mathfrak{g})I_\chi) = yy' + U(\mathfrak{g})I_\chi \) for \( y, y' \in U(\mathfrak{g}) \) such that \( [x, y], [x, y'] \in U(\mathfrak{g})I_\chi \) for all \( x \in \mathfrak{m} \).

In the special case that our fixed good grading is even, i.e. \( \mathfrak{g}_j = 0 \) for all odd \( j \), the algebras \( W(\chi) \) were already well studied by the end of the 1970s by Lynch \( [L] \).

Research partially supported by the NSF (grant no. DMS-0139019).

2000 Subject Classification: 17B37.
generalizing work of Kostant [K] treating regular nilpotent elements. Of course in the even case, we have simply that \( m = \bigoplus_{j \leq -2} g_j \). Letting \( p := \bigoplus_{j \geq 0} g_j \), the PBW theorem implies that

\[
U(g) = U(p) \oplus U(g)I_\chi.
\]

The projection \( pr_\chi : U(g) \rightarrow U(p) \) along this direct sum decomposition induces an isomorphism \( U(g)/U(g)I_\chi \cong U(p) \) which leads to an easier definition of the algebra \( W(\chi) \) in the even case as a subalgebra of \( U(p) \). To make this precise, define a twisted action of \( m \) on \( U(p) \) by \( x \cdot y := pr_\chi([x, y]) \) for \( x \in m \) and \( y \in U(p) \). Then \( pr_\chi \) induces an isomorphism between \( W(\chi) \) and subalgebra \( U(p)^m \) of \( U(p) \) consisting of all twisted \( m \)-invariants. This is the original definition used by Kostant and Lynch.

The most important examples of good gradings arise as follows. By the Jacobson-Morozov theorem, we can embed \( e \) into an \( sl_2 \)-triple \( (e, h, f) \), so \( [e, f] = h, [h, e] = 2e \) and \( [h, f] = -2f \). Then the representation theory of \( sl_2 \) implies that the ad-h-eigenspace decomposition of \( g \) is a good grading for \( e \). We refer to a good grading obtained in this way as a Dynkin grading. For a Dynkin grading, the module \( Q_\chi \) is a generalized Gelfand-Graev representation in the sense of Kawanaka [Ka] and Moeglin [M]. Its endomorphism algebra \( W(\chi) \) has been studied by Premet [P] as an application of results on Lie algebras in positive characteristic. Subsequently, a more direct approach has been given by Gan and Ginzburg [GG] which we follow here.

Returning to an arbitrary good grading, [EK] Lemma 1.1] shows that we can always embed the given element \( e \in g_2 \) into an \( sl_2 \)-triple \( (e, h, f) \) with \( h \in g_0 \) and \( f \in g_{-2} \). Letting \( c_\theta(f) \) denote the centralizer of \( f \) and \( m_\perp := \{ y \in g \mid [x, y] = 0 \text{ for all } x \in m \} \), the following crucial formula is proved as in [GG] §2.3, using [EK] Theorem 1.4]:

\[
m_\perp = [m, e] \oplus c_\theta(f).
\]

Remarkably, given this formula, all the arguments from [GG] in the context of Dynkin gradings extend absolutely unchanged to arbitrary good gradings. Let us just state briefly here the analogue of [P] Proposition 6.3] which we regard as the fundamental structure theorem for \( W(\chi) \); see also [GG] Theorem 4.1] and [L Theorem 2.3]. Introduce the Kazhdan filtration \( \cdots \subseteq F_d U(g) \subseteq F_{d+1} U(g) \subseteq \cdots \) of \( U(g) \) by declaring that a generator \( x \in g_j \) is of degree \( (j+2) \), i.e. \( F_d U(g) \) is the span of all monomials \( x_1 \cdots x_m \) for \( m \geq 0 \) and \( x_1 \in g_{j_1}, \ldots, x_m \in g_{j_m} \) with \( j_1 + 2 + \cdots + j_m + 2 \leq d \). Viewing \( W(\chi) \) as a subspace of the quotient \( U(g)/U(g)I_\chi \), there is an induced Kazhdan filtration on \( W(\chi) \); we denote the associated graded Poisson algebra by \( gr W(\chi) \). Recall also that the Slodowy slice through the nilpotent orbit containing \( e \) is the affine subspace \( e + c_\theta(f) \); see [S]. It has a natural Poisson structure which may be defined following [GG] §3.2 as the Hamiltonian reduction of the Kirillov-Kostant Poisson structure on \( g \). Now the basic fact is that there is a canonical isomorphism

\[
\nu : gr W(\chi) \rightarrow C[e + c_\theta(f)]
\]

of Poisson algebras; see [GG] §4.4] for its precise definition. Hence, \( W(\chi) \) can be viewed as a quantization of the Slodowy slice \( e + c_\theta(f) \). Moreover, up to canonical isomorphism, the algebra \( W(\chi) \) is independent of the particular choice of the Lagrangian subspace \( I \) of \( g_{-1} \); see [GG] §5.5].

Another fundamental result in this subject is Skryabin’s theorem proved in [SK] for Dynkin gradings; see also [GG] Theorem 6.1]. Again, Skryabin’s proof extends unchanged to any good grading. To state the result, let \( \mathcal{W}(\chi) \) be the category of
all \( \mathfrak{g} \)-modules on which \((x - \chi(x))\) act locally nilpotently for all \( x \in \mathfrak{m} \) (“generalized Whittaker modules”). If \( M \in \mathcal{W}(\chi) \) then the subspace
\[
M^m := \{ v \in M \mid (x - \chi(x))v = 0 \text{ for all } x \in \mathfrak{m} \} \cong \text{Hom}_{U(\mathfrak{g})}(Q, M)
\]
is a \( W(\chi) \)-module, hence \( M \mapsto M^m \) is a functor \( F \) from \( \mathcal{W}(\chi) \) to the category \( W(\chi)\)-Mod of all left \( W(\chi) \)-modules. Also, we have the functor \( G := Q_\chi\otimes W(\chi) \) from \( W(\chi)\)-Mod to \( \mathcal{W}(\chi) \). Skryabin’s theorem asserts that the functors \( F \) and \( G \) are quasi-inverse equivalences between \( \mathcal{W}(\chi) \) and \( W(\chi)\)-Mod. Moreover, every \( M \in \mathcal{W}(\chi) \) is an injective \( \mathfrak{m} \)-module and \( Q_\chi \) is a free right \( W(\chi) \)-module. Somewhat weaker results in the even case can already be found in the work of Kostant and Lynch; see for example [L, Theorems 2.4, 4.1].

In the remainder of the article we study the algebras \( W(\chi) \) in the special case that \( e \) is a nilpotent matrix of Jordan type \( p_1 \leq \cdots \leq p_n \) inside the Lie algebra \( \mathfrak{g} = \mathfrak{gl}_N \) over \( \mathbb{C} \), taking the bilinear form \((.,.)\) to be the usual trace form. Our main result gives an explicit set of generators and relations for the algebra \( W(\chi) \). One surprising consequence of our presentation is that in fact up to isomorphism the algebras \( W(\chi) \) only depend on the conjugacy class of \( e \), i.e. the partition \( \lambda = (p_n, p_{n-1}, \ldots, p_1) \) of \( N \), not on the particular choice of the good grading for \( e \).

The classification of good gradings for \( e \) is described in [EK, Theorem 4.2] in terms of certain diagrams called pyramids. A consequence of this classification is that, in type \( A \), it is sufficient in order to define all the algebras \( W(\chi) \) to restrict attention just to even good gradings. More precisely, every good grading for \( e \) is split in the sense that it is always possible to adjust the grading to obtain a new, even good grading for \( e \) with the property that the subalgebra \( \mathfrak{m} \) defined from the new grading coincides with the subalgebra \( \mathfrak{m} \) defined from the original grading for some particular choice of Lagrangian subspace \( l \). Hence the algebra \( W(\chi) \) defined from the new grading is equal to the algebra \( W(\chi) \) defined from the original grading using this choice of \( l \). (In the language of [EK, §4], the pyramid defining such a new grading may be obtained from the pyramid defining the original grading by shifting one place to the left all the boxes whose first coordinates are of different parity to the first coordinates of the boxes on the bottom row.)

So we may assume without loss of generality that the given good grading is even. The even good gradings for \( e \) are classified up to conjugacy in [EK, Proposition 4.3]; see also [L, Lemma 7.2]. Again we visualize the classification in terms of some pyramids as explained in [L] below. We will explain the idea in this introduction just with one example: the diagram
\[
\pi = \begin{array}{cccc}
1 & 3 & 6 \\
2 & 4 & 7 & 8 \\
\end{array}
\]
is a pyramid for \( \mathfrak{g} = \mathfrak{gl}_8 \) of height \( n = 3 \). Numbering the bricks \( 1, \ldots, 8 \) as indicated, the rows \( 1, \ldots, 3 \) from top to bottom and the columns \( 1, \ldots, 4 \) from left to right, we write row \((i)\) and \( \text{col}(i) \) for the row and column numbers of the \( i \)th brick in the pyramid, respectively. Denoting the \( ij \)-matrix unit by \( e_{i,j} \), the nilpotent matrix \( e \) associated to \( \pi \) is the matrix
\[
e = e_{1,3} + e_{3,6} + e_{2,4} + e_{4,7} + e_{7,8}
\]
defined by reading along the rows of the pyramid, and the even good grading associated to \( \pi \) is defined by declaring that \( e_{i,j} \) is of degree \( \text{col}(j) - \text{col}(i) \); actually, according to this definition, \( e \) is of degree 1 not 2 since in the case of an even good grading we prefer to divide all degrees by 2. Note that the Jordan type \((p_1, \ldots, p_n)\) of \( e \) in this example is \((1, 3, 4)\) (“row lengths”) and the parabolic subalgebra \( \mathfrak{p} := \bigoplus_{j \geq 0} \mathfrak{g}_j \) is of standard Levi shape \((2, 2, 3, 1)\) (“column heights”). From the pyramid \( \pi \) we also read off the level \( l := p_n \) and a certain shift matrix \( \sigma = (s_{i,j})_{1 \leq i, j \leq n} \) as explained in \([7]\) in our example,

\[
l = 4, \quad \sigma = \begin{pmatrix} 0 & 0 & 1 \\ 2 & 0 & 1 \\ 2 & 0 & 0 \end{pmatrix}.
\]

From now on we will denote the finite \( W \)-algebra \( W(\chi) \) instead by \( W(\pi) \); recall it may be defined in the even case as the subalgebra \( U(\mathfrak{p})^m \) of all twisted \( m \)-invariants in \( U(\mathfrak{p}) \).

Theorem \([11,1]\) below asserts for any pyramid \( \pi \) that \( W(\pi) \) is isomorphic to the shifted Yangian \( Y_{n,l}(\sigma) \) of level \( l \), namely, the quotient of the shifted Yangian \( Y_n(\sigma) \) by the two-sided ideal generated by elements \( \{D_1^{(r)}\}_{r \geq p_1} \). Here, \( Y_n(\sigma) \) denotes the algebra defined by generators \( \{D_1^{(r)}\}_{1 \leq i \leq n, r > 0}, \{E_i^{(r)}\}_{1 \leq i < n, r > s_{i,i+1}} \) and \( \{F_i^{(r)}\}_{1 \leq i < n, r > s_{i,i+1}} \) subject to the relations \([2.4] - [2.5] \) recorded below. In the special case that \( p_1 = \cdots = p_n \), i.e., all the Jordan blocks of \( e \) are of the same size \( l \), the pyramid \( \pi \) is an \( n \times l \) rectangle and the shift matrix \( \sigma \) is the zero matrix, the presentation is a variation on Drinfeld’s presentation \([11]\) for the Yangian \( Y_{n,l} \) of level \( l \) considered by Cherednik \([11]\). Hence in this case, \( W(\pi) \) is a quotient of the Yangian \( Y_n \) associated to the Lie algebra \( \mathfrak{gl}_n \), as was first noticed by Ragoucy and Sorba \([15]\).

The remainder of the article is organized as follows. In \([2]\) we define the shifted Yangian \( Y_n(\sigma) \) and prove a PBW theorem for it. In \([3]\) we introduce some more elaborate parabolic presentations for \( Y_n(\sigma) \) following \([BK1]\). These are important because they allow us in \([4]\) to write down an explicit formula for the so-called baby comultiplications. In \([5]\) we introduce the canonical filtration of \( Y_n(\sigma) \), which eventually turns out to correspond to the Kazhdan filtration of \( W(\pi) \). In \([6]\) we prove a PBW theorem for the finitely generated quotients \( Y_{n,l}(\sigma) \) of \( Y_n(\sigma) \). Then we turn our attention back to the finite \( W \)-algebras \( W(\pi) \), beginning in \([7]\) by explaining the classification of even good gradings in terms of pyramids. In \([8]\) we recall the setup of \([GG]\) in our special case in some detail. The most important section of the article is \([9]\) where we write down explicit formulae for elements of \( U(\mathfrak{p}) \) which eventually turn out to be precisely the generators \( D_i^{(r)}, E_i^{(r)} \) and \( F_i^{(r)} \) of \( W(\pi) \) that we are after. The main theorem is then proved by induction in \([10]\) the key tool for the induction step being the baby comultiplications. In \([11]\) we discuss more general comultiplications. Finally, \([12]\) gives a much simpler and more direct proof of the main theorem in the special case \( p_1 = \cdots = p_n \), using a different description of the generators of \( W(\pi) \) in this special case which is closely related to the Capelli determinant.

We finally note that one can replace the ground field \( \mathbb{C} \) used throughout the article with an arbitrary algebraically closed field of characteristic zero. In a subsequent article \([BK2]\), we will use the presentation for \( W(\pi) \) obtained here to study its highest weight representation theory. In particular we will explain the sense in which finite dimensional (rational) representations of \( W(\pi) \) categorify the polynomial representation of \( GL_{\infty} \) parametrized by the partition \( \lambda \).
Acknowledgements. We are grateful to Alexander Premet for illuminating discussions with the second author which triggered this work, Pavel Etingof for a useful discussion of [RS], and Gerhard Roehrle for showing us the paper [EK]. The first author also thanks Jeremy Rickard, Joseph Chuang and the Department of Mathematics at the University of Bristol for their hospitality whilst this paper was written up.

2. The shifted Yangian

Fix \( n \geq 1 \) and a matrix \( \sigma = (s_{i,j})_{1 \leq i,j \leq n} \) of non-negative integers ("shifts") such that
\[
s_{i,j} + s_{j,k} = s_{i,k}
\]
whenever \( |i - j| + |j - k| = |i - k| \). Note this means that \( s_{1,1} = \cdots = s_{n,n} = 0 \), and the matrix \( \sigma \) is completely determined by the upper diagonal entries \( s_{1,2}, s_{2,3}, \ldots, s_{n-1,n} \) and the lower diagonal entries \( s_{2,1}, s_{3,2}, \ldots, s_{n,n-1} \).

The shifted Yangian associated to the matrix \( \sigma \) is the algebra \( Y_n(\sigma) \) over \( \mathbb{C} \) defined by generators
\[
\{D^{(r)}_i\}_{1 \leq i \leq n, r > 0}, \quad \{E^{(r)}_i\}_{1 \leq i < n, r > s_{i,i+1}}, \quad \{F^{(r)}_i\}_{1 \leq i < n, r > s_{i+1,i}}
\]
subject to certain relations. In order to write down these relations, let
\[
D_i(u) := \sum_{r \geq 0} D^{(r)}_i u^{-r} \in Y_n(\sigma)[[u^{-1}]]
\]
where \( D^{(0)}_i := 1 \), and then define some new elements \( \tilde{D}^{(r)}_i \) of \( Y_n(\sigma) \) from the equation
\[
\tilde{D}_i(u) = \sum_{r \geq 0} \tilde{D}^{(r)}_i u^{-r} := -D_i(u)^{-1}.
\]
For example, \( \tilde{D}^{(0)}_i = -1, \tilde{D}^{(1)}_i = D^{(1)}_i, \tilde{D}^{(2)}_i = D^{(2)}_i - D^{(1)}_i D^{(1)}_i, \ldots \). With this notation, the relations are as follows.
\[
[D^{(r)}_i, D^{(s)}_j] = 0, \quad [F^{(r)}_i, D^{(s)}_j] = \delta_{i,j} \sum_{t=0}^{r+s-1} \tilde{D}^{(t)}_t D^{(r+s-1-t)}_i, \quad [D^{(r)}_i, E^{(s)}_j] = (\delta_{i,j} - \delta_{i,j+1}) \sum_{t=0}^{r-1} D^{(t)}_i E^{(r+s-1-t)}_j,
\]
\[
[D^{(r)}_i, F^{(s)}_j] = (\delta_{i,j+1} - \delta_{i,j}) \sum_{t=0}^{r-1} F^{(r+s-1-t)}_j D^{(t)}_i.
\]
\[
[E^{(r)}_i, E^{(s)}_i] = \sum_{t = s_{i,i+1} + 1}^{s - 1} E^{(t)}_i E^{(r+s-1-t)}_i - \sum_{t = s_{i,i+1} + 1}^{r - 1} E^{(t)}_i E^{(r+s-1-t)}_i, \quad (2.8)
\]

\[
[F^{(r)}_i, F^{(s)}_i] = \sum_{t = s_{i,i+1} + 1}^{r - 1} F^{(r+s-1-t)}_i F^{(t)}_i - \sum_{t = s_{i,i+1} + 1}^{s - 1} F^{(r+s-1-t)}_i F^{(t)}_i, \quad (2.9)
\]

\[
[E^{(r)}_i, E^{(s+1)}_{i+1}] - [E^{(r+1)}_i, E^{(s)}_{i+1}] = -E^{(r)}_i E^{(s)}_{i+1}, \quad (2.10)
\]

\[
[F^{(r+1)}_i, F^{(s)}_{i+1}] - [F^{(r)}_i, F^{(s+1)}_{i+1}] = -F^{(s)}_i F^{(r)}_i, \quad (2.11)
\]

\[
[E^{(r)}_i, E^{(s)}_j] = 0 \quad \text{if } |i - j| > 1, \quad (2.12)
\]

\[
[F^{(r)}_i, F^{(s)}_j] = 0 \quad \text{if } |i - j| > 1, \quad (2.13)
\]

\[
[E^{(r)}_i, E^{(s)}_j, E^{(t)}_j] + [E^{(s)}_i, E^{(r)}_j, E^{(t)}_j] = 0 \quad \text{if } |i - j| = 1, \quad (2.14)
\]

\[
[F^{(r)}_i, F^{(s)}_j, F^{(t)}_j] + [F^{(s)}_i, F^{(r)}_j, F^{(t)}_j] = 0 \quad \text{if } |i - j| = 1, \quad (2.15)
\]

for all admissible \( r, s, t, i, j \). (For an example of what we mean by “admissible” here, the relation (2.10) should be understood to hold for all \( i = 1, \ldots, n - 2, r > s_{i,i+1} \) and \( s > s_{i,i+1} + 2 \).)

If the matrix \( \sigma \) is the zero matrix, we denote \( Y_n(\sigma) \) simply by \( Y_n \). In this special case, the above presentation is a variation on Drinfeld’s presentation \([D]\) for the usual Yangian \( Y(\mathfrak{gl}_n) \) associated to the Lie algebra \( \mathfrak{gl}_n \); see \([BK1]\) Remark 5.12. We will prove in Corollary 2.2 below that the map sending the generators of \( Y_n(\sigma) \) to the elements with the same name in \( Y_n \) is an injective algebra homomorphism. Given this fact, the algebra \( Y_n(\sigma) \) is canonically a subalgebra of the usual Yangian \( Y_n \). By the relations, there is an anti-automorphism \( \tau : Y_n \to Y_n \) of order 2 defined by

\[
\tau(D^{(r)}_i) = D^{(r)}_i, \quad \tau(E^{(r)}_i) = F^{(r)}_i, \quad \tau(F^{(r)}_i) = E^{(r)}_i. \quad (2.16)
\]

This obviously interchanges the two subalgebras \( Y_n(\sigma) \) and \( Y_n(\sigma') \) of \( Y_n \), where \( \sigma' \) denotes the transpose of the matrix \( \sigma \). Hence \( \tau \) also induces an anti-isomorphism \( \tau : Y_n(\sigma) \to Y_n(\sigma') \). Suppose instead that \( \hat{\sigma} = (\hat{s}_{i,i})_{1 \leq i,j \leq n} \) is another shift matrix satisfying (2.11), such that \( \hat{s}_{i,i+1} + \hat{s}_{i+1,i} = s_{i,i+1} + s_{i+1,i} \) for all \( i = 1, \ldots, n - 1 \). Another check of relations shows that there is a unique algebra isomorphism \( \iota : Y_n(\sigma) \to Y_n(\hat{\sigma}) \) defined by

\[
\iota(D^{(r)}_i) = \hat{D}^{(r)}_i, \quad \iota(E^{(r)}_i) = \hat{E}^{(r-s_{i,i+1}+\hat{s}_{i,i+1})}_i, \quad \iota(F^{(r)}_i) = \hat{F}^{(r-s_{i,i+1}+\hat{s}_{i,i+1})}_i. \quad (2.17)
\]

(Here and later on we denote the generators \( D^{(r)}_i, E^{(r)}_i \) and \( F^{(r)}_i \) of \( Y_n(\sigma) \) instead by \( \hat{D}^{(r)}_i, \hat{E}^{(r)}_i \) and \( \hat{F}^{(r)}_i \) to avoid potential confusion.)

Let us now prove as promised that the canonical map \( Y_n(\sigma) \to Y_n \) is injective. Introduce the loop filtration \( L_0Y_n(\sigma) \subseteq L_1Y_n(\sigma) \subseteq \cdots \) by declaring that the generators \( D^{(r)}_i, E^{(r)}_i \) and \( F^{(r)}_i \) of \( Y_n(\sigma) \) are of degree \( (r - 1) \), i.e. \( L_dY_n(\sigma) \) is the span of all monomials in the generators of total degree \( \leq d \). For \( 1 \leq i < j \leq n \) and \( r > s_{i,j} \), define elements \( E^{(r)}_{i,j} \in Y_n(\sigma) \) recursively by

\[
E^{(r)}_{i,j+1} := E^{(r)}_{i,j}, \quad E^{(r)}_{i,j} := [E^{(r-s_{j,j-1})}_{i,j-1}, E^{(s_{j-1,j}+1)}_{j-1,j+1}]. \quad (2.18)
\]
Similarly, for $1 \leq i < j \leq n$ and $r > s_{i,j}$, define elements $F_{i,j}^{(r)} \in Y_n(\sigma)$ by

$$F_{i,i+1}^{(r)} := F_{i,1}^{(r)}, \quad F_{i,j}^{(r)} := [F_{j-1}^{(s_{i,j}-1+1)}, F_{i,j-1}^{(r-s_{i,j}-1)}]. \tag{2.19}$$

It is easy to see that $E_{i,j}^{(r)}$ and $F_{i,j}^{(r)}$ belong to $L_{r-1}Y_n(\sigma)$. For $1 \leq i, j \leq n$ and $r \geq s_{i,j}$, define

$$e_{i,j:r} := \begin{cases} \text{gr}_t D_i^{(r+1)} & \text{if } i = j, \\ \text{gr}_t E_{i,j}^{(r+1)} & \text{if } i < j, \\ \text{gr}_t F_{j,i}^{(r+1)} & \text{if } i > j, \end{cases} \tag{2.20}$$

all elements of the associated graded algebra $\text{gr}^t Y_n(\sigma)$. Let $\mathfrak{gl}_n[t]$ denote the Lie algebra $\mathfrak{gl}_n \otimes \mathbb{C}[t]$ on basis $\{e_{i,j:t^r}\}_{1 \leq i,j \leq n, r \geq 0}$, viewed as a graded Lie algebra so that $e_{i,j:t^r}$ is of degree $r$. In the special case $\sigma = 0$, the PBW theorem for the usual Yangian $Y_n$ implies that the ordered monomials in the elements $\{e_{i,j:r}\}_{1 \leq i,j \leq n, r \geq 0}$ are linearly independent in $\text{gr}^t Y_n$; see the proof of \cite{BK1} Lemma 5.10. Hence $\pi$ is an isomorphism in this case.

In general, the canonical map $Y_n(\sigma) \to Y_n$ is a homomorphism of filtered algebras, so induces a map $\text{gr}^t Y_n(\sigma) \to \text{gr}^t Y_n$ which sends $e_{i,j:r} \in \text{gr}^t Y_n(\sigma)$ to $e_{i,j:r} \in \text{gr}^t Y_n$ (despite the fact that it does not in general send $E_{i,j}^{(r+1)}, F_{i,j}^{(r+1)} \in Y_n(\sigma)$ to $E_{i,j}^{(r+1)}, F_{i,j}^{(r+1)} \in Y_n$ if $j - i > 1$). So the previous paragraph implies that the ordered monomials in the elements $\{e_{i,j:r}\}_{1 \leq i,j \leq n, r \geq s_{i,j}}$ are linearly independent in $\text{gr}^t Y_n(\sigma)$ too. Hence $\pi$ is an isomorphism in general.

\begin{corollary}
The canonical map $Y_n(\sigma) \to Y_n$ is injective.
\end{corollary}

\begin{proof}
We saw in the proof of Theorem \ref{thm:canonical} that the canonical map $Y_n(\sigma) \to Y_n$ is filtered and the associated graded map $\text{gr}^t Y_n(\sigma) \to \text{gr}^t Y_n$ is injective.
\end{proof}

The presentation of $Y_n(\sigma)$ is adapted to the natural triangular decomposition of this algebra. Let $Y_n^{+}(\sigma)$ denote the subalgebra of $Y_n(\sigma)$ generated by all the $D_i^{(r)}$’s, let $Y_n^{+}(1\nu)(\sigma)$ denote the subalgebra of $Y_n(\sigma)$ generated by all the $E_i^{(r)}$’s and let $Y_n^{-}(1\nu)(\sigma)$ denote the subalgebra generated by the all $F_i^{(r)}$’s.

\begin{theorem}
\begin{enumerate}
  \item The monomials in the elements $\{D_i^{(r)}\}_{1 \leq i \leq n, r \geq 0}$ taken in some fixed order form a basis for $Y_n^{+}(1\nu)(\sigma)$. \phantom{.}
  \item The monomials in the elements $\{E_{i,j}^{(r)}\}_{1 \leq i < j \leq n, r \geq s_{i,j}}$ taken in some fixed order form a basis for $Y_n^{+}(1\nu)(\sigma)$.
\end{enumerate}
\end{theorem}
(iii) The monomials in the elements \( \{ F_{i,j}^{(r)} \}_{1 \leq i < j \leq n, r > s_{i,j}} \) taken in some fixed order form a basis for \( Y_{(1^n)}^{-1}(\sigma) \).

(iv) The monomials in the union of the elements listed in (i)–(iii) taken in some fixed order form a basis for \( Y_n(\sigma) \).

Proof. Part (iv) follows from Theorem 2.1 and the PBW theorem for \( U(\mathfrak{g}\mathfrak{l}_n)[\ell](\sigma) \). The other parts are proved similarly, going back to (2.21).

\[ \square \]

Corollary 2.4. The natural multiplication map \( Y_{(1^n)}^{-1}(\sigma) \otimes Y_{(1^n)} \otimes Y_{(1^n)}^{-1}(\sigma) \rightarrow Y_n(\sigma) \) is a vector space isomorphism.

3. Parabolic presentations

We are going to need various more elaborate presentations of the shifted Yangian which are analogues of the parabolic presentations of [1]. In order to explain the relationship between all these presentations, we begin with an elementary remark about Gauss factorizations.

Let \( T = (T_{i,j})_{1 \leq i,j \leq n} \) be an \( n \times n \) matrix with entries in some ring such that the submatrices \( (T_{i,j})_{1 \leq i,j \leq m} \) are invertible for all \( m = 1, \ldots, n \). Fix also a tuple \( \nu = (\nu_1, \ldots, \nu_m) \) of positive integers summing to \( n \), which we think of as the shape of the standard Levi subgroup \( \mathfrak{g}\mathfrak{l}_\nu := \mathfrak{g}\mathfrak{l}_{\nu_1} \oplus \cdots \oplus \mathfrak{g}\mathfrak{l}_{\nu_m} \) of \( \mathfrak{g}\mathfrak{l}_n \). Working with \( m \times m \) block matrices so that the \( ab \)-block is of size \( \nu_a \times \nu_b \), the matrix \( T \) possesses a unique Gauss factorization \( T = \nu F \nu D \nu E \) where \( \nu D \) is a block diagonal matrix, \( \nu E \) is a block upper unitriangular matrix, and \( \nu F \) is a block lower unitriangular matrix:

\[
\nu D = \begin{pmatrix}
\nu D_1 & 0 & \cdots & 0 \\
0 & \nu D_2 & \cdots & 0 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & \nu D_{m-1} & 0 \\
0 & \cdots & 0 & \nu D_m
\end{pmatrix},
\]

\[
\nu E = \begin{pmatrix}
I_{\nu_1} & \nu E_1 & * & \cdots & * \\
0 & I_{\nu_2} & \nu E_2 & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & I_{\nu_{m-1}} & \nu E_{m-1} \\
0 & \cdots & 0 & I_{\nu_m}
\end{pmatrix},
\]

\[
\nu F = \begin{pmatrix}
I_{\nu_1} & 0 & \cdots & 0 \\
\nu F_1 & I_{\nu_2} & \cdots & 0 \\
* & \nu F_2 & I_{\nu_3} & \cdots \\
\vdots & \ddots & \ddots & \ddots \\
* & \cdots & * & \nu F_{m-1} & I_{\nu_m}
\end{pmatrix}.
\]

The diagonal blocks of \( \nu D \) define matrices \( \nu D_1, \ldots, \nu D_m \), the upper diagonal blocks of \( \nu E \) define matrices \( \nu E_1, \ldots, \nu E_{m-1} \), and the lower diagonal blocks of \( \nu F \) define matrices \( \nu F_1, \ldots, \nu F_{m-1} \). So \( \nu D_a \) is a \( \nu_a \times \nu_a \) matrix, \( \nu E_a \) is a \( \nu_a \times \nu_{a+1} \) matrix, and \( \nu F_a \) is a \( \nu_{a+1} \times \nu_a \) matrix. Now consider what happens when we split a block into two: suppose that \( \nu_b = \alpha + \beta \) for some \( 1 \leq b \leq m \) and \( \alpha, \beta \geq 1 \), and let \( \mu = (\nu_1, \ldots, \nu_{b-1}, \alpha, \beta, \nu_{b+1}, \ldots, \nu_m) \). The following lemma shows how to compute the matrices \( \mu D_1, \ldots, \mu D_{m+1}, \mu E_1, \ldots, \mu E_m \) and \( \mu F_1, \ldots, \mu F_{m-1} \) just from knowledge of the matrices \( \nu D_1, \ldots, \nu D_m, E_1, \ldots, E_m, F_1, \ldots, F_{m-1} \).
Lemma 3.1. In the above notation, define an $\alpha \times \alpha$ matrix $A$, an $\alpha \times \beta$ matrix $B$, a $\beta \times \alpha$ matrix $C$ and a $\beta \times \beta$ matrix $D$ from the equation

$$\nu D_b = \begin{pmatrix} I_\alpha & 0 \\ C & I_\beta \end{pmatrix} \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix} \begin{pmatrix} I_\alpha & B \\ 0 & I_\beta \end{pmatrix}. $$

Then,

(i) $\nu D_a = \nu D_a$ for $a < b$, $\nu D_b = A$, $\nu D_{b+1} = D$, and $\nu D_c = \nu D_{c-1}$ for $c > b + 1$;

(ii) $\nu E_a = \nu E_a$ for $a < b - 1$, $\nu E_{b-1}$ is the submatrix consisting of the first $\alpha$ columns of $\nu E_{b-1}$, $\nu E_b = B$, $\nu E_{b+1}$ is the submatrix consisting of the last $\beta$ rows of $\nu E_b$, and $\nu E_c = \nu E_{c-1}$ for $c > b + 1$;

(iii) $\nu F_a = \nu F_a$ for $a < b - 1$, $\nu F_{b-1}$ is the submatrix consisting of the first $\alpha$ rows of $\nu F_{b-1}$, $\nu F_b = C$, $\nu F_{b+1}$ is the submatrix consisting of the last $\beta$ columns of $\nu F_b$, and $\nu F_c = \nu F_{c-1}$ for $c > b + 1$;

Proof. Multiply matrices. \hfill \square

Now let us briefly recall the parabolic presentations for the Yangian $Y_n$ from [BKT]. As in [MNO], the Yangian can be defined in terms of the RTT presentation as the algebra over $\mathbb{C}$ defined by generators $\{T_{i,j}^{(r)}\}_{1 \leq i, j \leq n, r > 0}$ subject just to the relations

$$[T_{i,j}^{(r)}, T_{h,k}^{(s)}] = \sum_{t=0}^{\min(r,s)-1} \left( T_{i,k}^{(r+s-1-t)} T_{h,j}^{(t)} - T_{h,j}^{(t)} T_{i,k}^{(r+s-1-t)} \right) \quad (3.1)$$

for every $1 \leq h, i, j, k \leq n$ and $r, s > 0$, where $T_{i,j}^{(0)} := \delta_{i,j}$. Let $T_{i,j}^{(r)}(u) := \sum_{i \geq 0} T_{i,j}^{(r)} u^{-r}$ and let $T(u)$ denote the $n \times n$ matrix $(T_{i,j}(u))_{1 \leq i, j \leq n}$. Given a shape $\nu = (\nu_1, \ldots, \nu_m)$, consider the Gauss factorization $T(u) = F(u)D(u)E(u)$ where $D(u)$ is a block diagonal matrix, $E(u)$ is a block upper unitriangular matrix and $F(u)$ is a block lower unitriangular matrices, all block matrices being of shape $\nu$ like before. We will from now on omit any extra superscript $\nu$ since it should be clear from the context which shape $\nu$ we have in mind. The diagonal blocks of $D(u)$ define matrices $D_1(u), \ldots, D_m(u)$, the upper diagonal blocks of $E(u)$ define matrices $E_1(u), \ldots, E_{m-1}(u)$, and the lower diagonal blocks of $F(u)$ define matrices $F_1(u), \ldots, F_{m-1}(u)$. Thus $D_a(u) = (D_{a,i,j}(u))_{1 \leq i, j \leq \nu_a}$ is a $\nu_a \times \nu_a$ matrix, $E_a(u) = (E_{a,i,j}(u))_{1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1}}$ is a $\nu_a \times \nu_{a+1}$ matrix, and

$$F_a(u) = (F_{a,i,j}(u))_{1 \leq i \leq \nu_{a+1}, 1 \leq j \leq \nu_a}$$

is a $\nu_{a+1} \times \nu_a$ matrix. Write

$$D_{a;i,j}(u) = \sum_{r \geq 0} D_{a;i,j}^{(r)} u^{-r}, \quad E_{a;i,j}(u) = \sum_{r > 0} E_{a;i,j}^{(r)} u^{-r}, \quad F_{a;i,j}(u) = \sum_{r > 0} F_{a;i,j}^{(r)} u^{-r},$$

thus defining elements $D_{a;i,j}^{(r)}, E_{a;i,j}^{(r)}$ and $F_{a;i,j}^{(r)}$ of $Y_n$, all dependent of course on the fixed choice of $\nu$. Now [BKT] Theorem A] shows that the elements

$$\{D_{a;i,j}^{(r)}\}_{1 \leq a, m, 1 \leq i, j \leq \nu_a, r > 0},$$

$$\{E_{a;i,j}^{(r)}\}_{1 \leq a, m, 1 \leq i, \nu_a, 1 \leq j \leq \nu_{a+1}, r > 0},$$

$$\{F_{a;i,j}^{(r)}\}_{1 \leq a, m, 1 \leq \nu_{a+1}, 1 \leq j \leq \nu_a, r > 0}$$

generate $Y_n$ subject only to the relations (3.3) and (3.11) below (taking the shift matrix there to be the zero matrix). For example, the presentation for $Y_n$ from (2) is the special case $\nu = (1^n)$, in which case we denote $D_{i;i,1}^{(r)}, E_{i;i,1}^{(r)}$ and $F_{i;i,1}^{(r)}$ simply by $D_i^{(r)}, E_i^{(r)}$ and
\( F_i^{(r)} \) respectively, while the RTT presentation from (3.1) is the special case \( \nu = (n) \), in which case \( D_{i,j}^{(r)} = T_{i,j}^{(r)} \).

We are going to adapt these parabolic presentations to the shifted Yangian \( Y_n(\sigma) \). Return to the setup of (22) assuming that \( \sigma = (s_{i,j})_{1 \leq i,j \leq n} \) is a fixed shift matrix. Suppose in addition that the shape \( \nu = (\nu_1, \ldots, \nu_m) \) is \textit{admissible} for \( \sigma \), meaning that \( s_{i,j} = 0 \) for all \( \nu_1 + \cdots + \nu_{a-1} + 1 \leq i,j \leq \nu_1 + \cdots + \nu_a \) and \( a = 1, \ldots, m \). We will adopt the shorthand

\[
\nu_{a,b}(\nu) := \nu_{\nu_1+\cdots+\nu_a, \nu_1+\cdots+\nu_b},
\]

(3.2)
The shifts \((s_{i,j})_{1 \leq i,j \leq n}\) can be recovered from the “relative” shifts \((s_{a,b}(\nu))_{1 \leq a,b \leq m}\) given the admissible shape \( \nu \).

Define a new algebra \( \nu Y_n(\sigma) \) over \( \mathbb{C} \), which will shortly be identified with \( Y_n(\sigma) \) from (22) by generators

\[
\{ \tilde{D}_{a,i,j}^{(s)} \}_{1 \leq a \leq m, 1 \leq i,j \leq n, r > 0},
\]

\[
\{ \tilde{F}_{a,i,j}^{(s)} \}_{1 \leq a < s_{a,b}(\nu), 1 \leq i \leq n, r > s_{a,a+1}(\nu)}
\]

subject to certain relations. To write down these relations, we must introduce some \( \nu \)-dependent data. Let \( \tilde{D}_{a,i,j}(0) := \delta_{i,j}, \tilde{D}_{a,i,j}(u) := \sum_{r \geq 0} \tilde{D}_{a,i,j}^{(r)} u^{-r} \) and introduce the matrix \( \tilde{D}_{a}(u) := (\tilde{D}_{a,i,j}(u))_{1 \leq i,j \leq n} \), which will shortly be identified with \( \nu Y_n(\sigma) \) for each \( a = 1, \ldots, m \), \( 1 \leq i,j \leq \nu_a \) and \( r \geq 0 \). In particular, \( \tilde{D}_{a,0}^{(0)} = -\delta_{i,j} \) and \( \tilde{D}_{a,1}^{(1)} = \tilde{D}_{a,i,j}^{(1)} \). Now the relations are:

\[
[D_{a,i,j}^{(r)}, \tilde{D}_{b,h,k}^{(s)}] = \delta_{a,b} \sum_{t=0}^{\min(r,s)-1} D_{a,i,k}^{(r+s-t)} D_{a,h,j}^{(t)} - D_{a,i,k}^{(t)} D_{a,h,j}^{(r+s-t) - t},
\]

(3.3)

\[
[E_{a,i,j}^{(s)}, \tilde{F}_{b,h,k}^{(s)}] = \delta_{a,b} \sum_{r=0}^{s-1} \tilde{D}_{a,i,k}^{(r+s-1-t)} D_{a,h,j}^{(t)} - D_{a,i,k}^{(t)} \tilde{D}_{a,h,j}^{(r+s-1-t)},
\]

(3.4)

\[
[D_{a,i,j}^{(r)}, E_{b,h,k}^{(s)}] = \delta_{a,b} \sum_{t=0}^{r-1} \sum_{g=0}^{\nu_a} D_{a,i,g}^{(t)} \tilde{E}_{a,g,k}^{(r+s-t)} \delta_{h,j} - \delta_{a,b+1} \sum_{t=0}^{r-1} \sum_{g=0}^{\nu_a} D_{b+1,i,k}^{(t)} \tilde{E}_{b,h,j}^{(r+s-1-t)},
\]

(3.5)

\[
[D_{a,i,j}^{(r)}, F_{b,h,k}^{(s)}] = \delta_{a,b+1} \sum_{t=0}^{r-1} \sum_{g=0}^{\nu_a} \tilde{F}_{b,i,k}^{(r+s-t-1)} D_{b+1,h,j}^{(t)} - \delta_{a,b} \delta_{i,k} \sum_{t=0}^{r-1} \sum_{g=0}^{\nu_a} \tilde{F}_{a,h,g}^{(r+s-1-t)} D_{a,g,j}^{(t)},
\]

(3.6)

\[
[E_{a,i,j}^{(s)}, \tilde{E}_{a,h,k}^{(s)}] = \sum_{t=s_{a,a+1}(\nu)+1}^{s-1} \tilde{E}_{a,i,k}^{(t)} \tilde{E}_{a,h,j}^{(r+s-1-t)} - \sum_{t=s_{a,a+1}(\nu)+1}^{s-1} \tilde{E}_{a,i,k}^{(t)} \tilde{E}_{a,h,j}^{(r+s-1-t)},
\]

(3.7)

\[
[E_{a,i,j}^{(s)}, \tilde{F}_{a,h,k}^{(s)}] = \sum_{t=s_{a+1,a}(\nu)+1}^{r-1} \tilde{F}_{a,i,k}^{(r+s-1-t)} \tilde{F}_{a,h,j}^{(t)} - \sum_{t=s_{a+1,a}(\nu)+1}^{r-1} \tilde{F}_{a,i,k}^{(r+s-1-t)} \tilde{F}_{a,h,j}^{(t)},
\]

(3.8)
Theorem 2.3. ≤ the generators for all admissible \( \nu \) prove that this canonical homomorphism is injective and that its image is independent of the names (the ones we defined above in terms of Gauss factorizations). We are going to prove given in (iii).

Observe right away that there is a canonical homomorphism \( \nu: Y_n(\sigma) \to Y_n \) mapping the generators \( D_{a;i,j}, E_{a;i,j} \) and \( F_{a;i,j} \) of \( \nu Y_n(\sigma) \) to the elements of \( Y_n \) with the same names (the ones we defined above in terms of Gauss factorizations). We are going to prove that this canonical homomorphism is injective and that its image is independent of the particular choice of the admissible shape \( \nu \). In particular this will identify \( \nu Y_n(\sigma) \) with the algebra \( Y_n(\sigma) \) from § since that is the special case \( \nu = (1^n) \) of the present definition.

The proof that the canonical map \( \nu Y_n(\sigma) \to Y_n \) is injective is an extension of the proof given in §. For \( 1 \leq a < b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b \) and \( r > s_{a,b}(\nu) \), we define elements \( E_{a,b;i,j} \) inductively by

\[
E_{a,b;i,j}^{(r)} := \begin{cases} E_{a;i,j}^{(r)} & \text{if } a < b \\ E_{a;i,j}^{(r)} := [E_{a;i,j}^{(r-s_{a,b}(\nu))}, E_{b;i,j}^{(s_{a,b}(\nu)+1)}] \end{cases} \tag{3.15}
\]

where \( 1 \leq k \leq \nu_b-1 \). By the relations this definition is independent of the choice of \( k \); see for instance (6.9)) for a similar argument. Similarly for \( 1 \leq a < b \leq m, 1 \leq i \leq \nu_b, 1 \leq j \leq \nu_a \) and \( r > s_{b,a}(\nu) \), we define elements \( F_{a,b;i,j}^{(r)} \) by

\[
F_{a,b;i,j}^{(r)} := \begin{cases} F_{a;i,j}^{(r)} & \text{if } a < b \\ F_{a;i,j}^{(r)} := [F_{a;i,j}^{(r-s_{b,a}(\nu))}, F_{b;i,j}^{(s_{b,a}(\nu)+1)}] \end{cases} \tag{3.16}
\]

where \( 1 \leq k \leq \nu_b-1 \). Also let \( Y_\nu \) denote the subalgebra of \( \nu Y_n(\sigma) \) generated by all the \( D_{a;i,j}^{(r)} \)'s, let \( Y_\nu^+(\sigma) \) denote the subalgebra generated by all the \( E_{a;i,j}^{(r)} \)'s and let \( Y_\nu^-(\sigma) \) denote the subalgebra generated by all the \( F_{a;i,j}^{(r)} \)'s. The following theorem generalizes Theorem 2.3.

**Theorem 3.2.**

(i) The monomials in the elements \( \{D_{a;i,j}^{(r)}\}_{a=1,...,m,1 \leq i,j \leq \nu_a, r > 0} \) taken in some fixed order form a basis for \( Y_\nu \).

(ii) The monomials in the elements \( \{E_{a;i,j}^{(r)}\}_{1 \leq a < b \leq m, a \leq i \leq \nu_a, b \leq j \leq \nu_b, r > s_{a,b}(\nu)} \) taken in some fixed order form a basis for \( Y_\nu^+(\sigma) \).

(iii) The monomials in the elements \( \{F_{a;i,j}^{(r)}\}_{1 \leq a < b \leq m, a \leq i \leq \nu_a, b \leq j \leq \nu_b, r > s_{b,a}(\nu)} \) taken in some fixed order form a basis for \( Y_\nu^-(\sigma) \).

(iv) The monomials in the union of the elements listed in (i)-(iii) taken in some fixed order form a basis for \( \nu Y_n(\sigma) \).
Proof. Introduce the loop filtration $L_0 \nu Y_n(\sigma) \subseteq L_1 \nu Y_n(\sigma) \subseteq \cdots$ of $\nu Y_n(\sigma)$ by declaring that the generators $D_{a;i,j}^{(r)}$, $E_{a;i,j}^{(r)}$ and $F_{a;i,j}^{(r)}$ are all of degree $(r - 1)$. Define elements $\{e_{i,j;r}\}_{1 \leq i,j \leq n, r \geq s_{i,j}}$ of the associated graded algebra $\text{gr}^L \nu Y_n(\sigma)$ from the equations
\begin{align}
\text{gr}^L D_{a;i,j}^{(r+1)} &= e_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j}, \\
\text{gr}^L E_{a,b;i,j}^{(r+1)} &= e_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j}, \\
\text{gr}^L F_{a,b;i,j}^{(r+1)} &= e_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j}.
\end{align}

Following the proof of [BK1, Lemma 6.7], one checks that these elements satisfy the relations (3.3)–(3.14). Hence, there is a well-defined surjective homomorphism $\pi : U(\mathfrak{gl}_n[\mathbb{t}](\sigma)) \to \text{gr}^L \nu Y_n(\sigma)$ mapping $e_{i,j;r} \in U(\mathfrak{gl}_n[\mathbb{t}](\sigma))$ to $e_{i,j;r} \in \text{gr}^L \nu Y_n(\sigma)$.

In the special case $\sigma = 0$, we already know that $\nu Y_n(\sigma)$ is the usual Yangian $Y_n$, one checks using Lemma 3.1 and induction on the length $m$ of the shape $\nu$ that the element $e_{i,j;r}$ defined here is equal to $\text{gr}^L T_{i,j}^{(r+1)}$. In particular $e_{i,j;r}$ coincides with the element of $\text{gr}^L Y_n$ defined by (2.20). Hence like in the proof of Theorem 2.3, the PBW theorem for the usual Yangian implies that the ordered monomials in the elements $\{e_{i,j;r}\}_{1 \leq i,j \leq n, r \geq 0}$ are linearly independent in $\text{gr}^L Y_n$, and $\pi$ is an isomorphism.

In general, the canonical map $\nu Y_n(\sigma) \to Y_n$ is a homomorphism of filtered algebras, so induces a map $\text{gr}^L \nu Y_n(\sigma) \to \text{gr}^L Y_n$ which maps $e_{i,j;r} \in \text{gr}^L \nu Y_n(\sigma)$ to $e_{i,j;r} \in \text{gr}^L Y_n$. So the previous paragraph implies that the ordered monomials in the elements $\{e_{i,j;r}\}_{1 \leq i,j \leq n, r \geq s_{i,j}}$ are linearly independent in $\text{gr}^L \nu Y_n(\sigma)$ too. Hence $\pi$ is an isomorphism in general.

The theorem now follows like Theorem 2.3. \hfill \Box

The following two corollaries generalize Corollaries 2.2 and 2.4.

**Corollary 3.3.** The canonical map $\nu Y_n(\sigma) \to Y_n$ is injective.

**Corollary 3.4.** Multiplication $Y^\nu_\mu(\sigma) \times Y^\nu_\mu(\sigma) \to \nu Y_n(\sigma)$ is a vector space isomorphism.

So now for each admissible shape $\nu$, we have defined a subalgebra $\nu Y_n(\sigma)$ of $Y_n$. It remains to see that these subalgebras coincide for different $\nu$. Suppose $\nu_0 = \alpha + \beta$ for some $1 \leq b \leq m$ and $\alpha, \beta \geq 1$, and let $\mu = (\nu_1, \ldots, \nu_{b-1}, \alpha, \beta, \nu_{b+1}, \ldots, \nu_m)$. Then it suffices to show that $\nu Y_n(\sigma) = \mu Y_n(\sigma)$ as subalgebras of $Y_n$. Using Lemma 3.1 one checks that $\mu Y_n(\sigma) \subseteq \nu Y_n(\sigma)$. Now the equality $\mu Y_n(\sigma) = \nu Y_n(\sigma)$ follows easily because we have already seen in the proof of Theorem 3.2 that their associated graded algebras are equal in $\text{gr}^L Y_n$. We have now proved that the relations (3.3)–(3.14) give presentations for the shifted Yangian $Y_n(\sigma) = \nu Y_n(\sigma)$ for each admissible shape $\nu$.

**Remark 3.5.** As a first application of these parabolic presentations, one can introduce analogues of parabolic subalgebras of $Y_n(\sigma)$: for an admissible shape $\nu$, define $Y^\nu_\mu(\sigma) := Y^\nu_\mu Y^\nu_\sigma(\sigma)$ and $Y^\nu_\mu(\sigma) := Y^\nu_\mu(\sigma) Y^\nu_\sigma$. By the relations, these are indeed subalgebras of $Y_n(\sigma)$. Moreover, there are obvious surjective homomorphisms $Y^\nu_\mu(\sigma) \to Y^\nu_\sigma$ and $Y^\nu_\sigma(\sigma) \to Y^\nu_\sigma$ with kernels generated by all $E_{a;i,j}^{(r)}$ and all $F_{a;i,j}^{(r)}$ respectively.

**Remark 3.6.** In this remark, we describe the maps $\tau$ and $\iota$ from (2.16)–(2.17) in terms of the parabolic generators. The anti-isomorphism $\tau$ satisfies
\begin{align}
\tau(D_{a;i,j}^{(r)}) = D_{a;i,j}^{(r)}, \quad \tau(E_{a;i,j}^{(r)}) = F_{a;i,j}^{(r)}, \quad \tau(F_{a;i,j}^{(r)}) = E_{a;i,j}^{(r)}.
\end{align}
The usual Yangian $Y$ equation of the Yangian $Y$ evaluation homomorphism. There is also the admissible shape of smallest possible length $m$ for $(\nu_1, \ldots, \nu_m)$, parabolic presentation defined relative to this fixed shape. Theorem 4.1.

Let $\Delta$ be the minimal admissible shape for $\sigma = (\nu_1, \ldots, \nu_m)$, admissible if $\nu_1 + \cdots + \nu_{a-1} + 1 \leq i, j \leq \nu_1 + \cdots + \nu_a$ and $a = 1, \ldots, m$. Throughout the section, $\nu$ will denote the minimal admissible shape for $\sigma$, that is, the admissible shape of smallest possible length $m$. We will always work in terms of the parabolic presentation defined relative to this fixed shape $\nu$. For example in the case of the Yangian $Y_n$, this is the RTT presentation from (3.1).

Consider first the special case that $\sigma$ is the zero matrix, i.e. the case when $Y_n(\sigma)$ is the usual Yangian $Y_n$. It is well known that $Y_n$ is a Hopf algebra, with comultiplication $\Delta : Y_n \rightarrow Y_n \otimes Y_n$ which may be defined in terms of the RTT presentation by the equation

$$\Delta(T_{i,j}^{(r)}) = \sum_{s=0}^{r} \sum_{k=1}^{n} T_{i,k}^{(s)} \otimes T_{k,j}^{(r-s)}. \quad (4.1)$$

There is also the evaluation homomorphism $\kappa_1 : Y_n \rightarrow U(\mathfrak{gl}_n)$ defined by

$$\kappa_1(T_{i,j}^{(r)}) = \begin{cases} e_{i,j} & \text{if } r = 1, \\ 0 & \text{if } r > 1. \end{cases} \quad (4.2)$$

Let $\Delta_R := (\text{id} \otimes \kappa_1) \circ \Delta$ and $\Delta_L := (\kappa_1 \otimes \text{id}) \circ \Delta$, thus defining algebra homomorphisms

$$\Delta_R : Y_n \rightarrow Y_n \otimes U(\mathfrak{gl}_n), \quad T_{i,j}^{(r)} \mapsto T_{i,j}^{(r)} \otimes 1 + \sum_{k=1}^{n} T_{i,k}^{(r-1)} \otimes e_{k,j}, \quad (4.3)$$

$$\Delta_L : Y_n \rightarrow U(\mathfrak{gl}_n) \otimes Y_n, \quad T_{i,j}^{(r)} \mapsto 1 \otimes T_{i,j}^{(r)} + \sum_{k=1}^{n} e_{i,k} \otimes T_{k,j}^{(r-1)}. \quad (4.4)$$

The following theorem defines analogous “baby comultiplications” for the shifted Yangians in general.

**Theorem 4.1.** Let $\nu = (\nu_1, \ldots, \nu_m)$ be the minimal admissible shape for $\sigma$ and set $t := \nu_m$. For $1 \leq i, j \leq t$, let $\hat{e}_{i,j} := e_{i,j} + \delta_{i,j}(n-t) \in U(\mathfrak{gl}_t)$.

(i) If either $t = n$ or $\nu_{n-t,n-t+1} \neq 0$, define $\hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i, j \leq n}$ from

$$\hat{s}_{i,j} = \begin{cases} s_{i,j} - 1 & \text{if } i \leq n - t < j, \\ s_{i,j} & \text{otherwise}. \end{cases} \quad (4.5)$$

Now let us explain the real reason why the parabolic presentations of $Y_n(\sigma)$ from (3.1) are so important. Fix a shift matrix $\sigma = (s_{i,j})_{1 \leq i, j \leq n}$, where $s_{i,j} = 0$ for all $|i| + \cdots + |s_{a-1}(\nu)| + 1 \leq i, j \leq |\nu_1| + \cdots + |\nu_a|$ and $a = 1, \ldots, m$. For each $i, j$ in this admissible shape, this is the same map as in (2.17). If either $t = n$ or $\nu_{n-t,n-t+1} \neq 0$, define $\hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i, j \leq n}$ from

$$\hat{s}_{i,j} = \begin{cases} s_{i,j} - 1 & \text{if } i \leq n - t < j, \\ s_{i,j} & \text{otherwise}. \end{cases} \quad (4.5)$$

Now use Lemma 3.1 to check inductively that this is the same map as in (2.17).
Then, there is a unique algebra homomorphism $\Delta_R : Y_n(\sigma) \to Y_n(\hat{\sigma}) \otimes U(\mathfrak{g}_t)$ such that
\[
D^{(r)}_{a;i,j} \mapsto \hat{D}^{(r)}_{a;i,j} \otimes 1 + \delta_{a,m} \sum_{k=1}^{t} \hat{D}^{(r-1)}_{a;i,k} \otimes \hat{e}_{k,j},
\]
\[
E^{(r)}_{a;i,j} \mapsto \hat{E}^{(r)}_{a;i,j} \otimes 1 + \delta_{a,m-1} \sum_{k=1}^{t} \hat{E}^{(r-1)}_{a;i,k} \otimes \hat{e}_{k,j},
\]
\[
F^{(r)}_{a;i,j} \mapsto \hat{F}^{(r)}_{a;i,j} \otimes 1.
\]
(ii) If either $t = n$ or $s_{n-t+1, n-t} \neq 0$, define $\hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n}$ from
\[
\hat{s}_{i,j} = \begin{cases} 
    s_{i,j} - 1 & \text{if } j \leq n - t < i, \\
    s_{i,j} & \text{otherwise.}
\end{cases}
\]
Then, there is a unique algebra homomorphism $\Delta_L : Y_n(\sigma) \to U(\mathfrak{g}_t) \otimes Y_n(\hat{\sigma})$ such that
\[
D^{(r)}_{a;i,j} \mapsto 1 \otimes \hat{D}^{(r)}_{a;i,j} + \delta_{a,m} \sum_{k=1}^{t} \hat{e}_{i,k} \otimes \hat{D}^{(r-1)}_{a;k,j},
\]
\[
E^{(r)}_{a;i,j} \mapsto 1 \otimes \hat{E}^{(r)}_{a;i,j},
\]
\[
F^{(r)}_{a;i,j} \mapsto 1 \otimes \hat{F}^{(r)}_{a;i,j} + \delta_{a,m-1} \sum_{k=1}^{t} \hat{e}_{i,k} \otimes \hat{F}^{(r-1)}_{a;k,j}.
\]
(In both (i) and (ii) we are working in terms of the parabolic generators relative to the fixed shape $\nu$.)

Proof. Check the relations (3.3)–(3.14) (to check the relations (3.13) and (3.14) one needs to use (3.7), (3.8) and (3.9), (3.10) several times).

The next lemma explains how to compute the baby comultiplications on the higher root elements $E^{(r)}_{a,b;i,j}$ and $F^{(r)}_{a,b;i,j}$, still working in terms of the minimal admissible shape $\nu$ for $\sigma$.

Lemma 4.2. (i) Under the hypotheses of Theorem 4.1(i), we have for $1 \leq a < b - 1 < m$ and all admissible $i, j, r$ that
\[
\Delta_R(E^{(r)}_{a,b;i,j}) = \begin{cases} 
    \hat{E}^{(r)}_{a,b;i,j} \otimes 1 & \text{if } b < m, \\
    [\hat{E}_{a,m-1;i,h}^{(r-s_{m-1,m}(\nu))}, \hat{E}_{a,m-1;m,j}^{(s_{m-1,m}(\nu)+1)}] \otimes 1 + \sum_{k=1}^{t} \hat{e}_{i,k} \otimes \hat{e}_{k,j} & \text{if } b = m,
\end{cases}
\]
\[
\Delta_R(F^{(r)}_{a,b;i,j}) = \hat{F}^{(r)}_{a,b;i,j} \otimes 1,
\]
for any $1 \leq h \leq \nu_{m-1}$.

(ii) Under the hypotheses of Theorem 4.1(ii), we have for $1 \leq a < b - 1 < m$ and all admissible $i, j, r$ that
\[
\Delta_L(E^{(r)}_{a,b;i,j}) = 1 \otimes \hat{E}^{(r)}_{a,b;i,j},
\]
\[
\Delta_L(F^{(r)}_{a,b;i,j}) = \begin{cases} 
    1 \otimes \hat{F}^{(r)}_{a,b;i,j} & \text{if } b < m, \\
    1 \otimes [\hat{F}_{a,m-1;i,h}^{(s_{m-1,m}(\nu)+1)}, \hat{F}_{a,m-1;m,j}^{(r-s_{m-1,m}(\nu))}] + \sum_{k=1}^{t} \hat{e}_{i,k} \otimes \hat{e}_{k,j} & \text{if } b = m,
\end{cases}
\]
for any $1 \leq h \leq \nu_{m-1}$. 

\]
Proof. Let us just explain how to compute $\Delta_R(E_{a,m;i,j}^{(r)})$ for $1 \leq a < m - 1$, since all the other cases are similar. By definition, $E_{a,m;i,j}^{(r)} = [E_{a,m-1;i,h}^{(r)}, E_{m-1;i,h}^{(r)(s_{m-1,1})(m)((s_{m-1,1})(m) + 1)}]$ for any $1 \leq h \leq \nu_{m-1}$. Clearly $\Delta_R(E_{a,m-1;i,h}^{(r)}) = \hat{E}_{a,m-1;i,h}^{(r)(s_{m-1,1})(m)} \otimes 1$. Hence,

$$\Delta_R(E_{a,m;i,j}^{(r)}) = \left[\hat{E}_{a,m-1;i,h}^{(r)(s_{m-1,1})(m)}, \hat{E}_{m-1;i,h}^{(r)(s_{m-1,1})(m) + 1}\right] \otimes 1 + \sum_{k=1}^{t} \hat{E}_{a,m;k}^{(r)(s_{m-1,1})(m)} \otimes \hat{e}_{k,j},$$

as claimed. $\square$

Remark 4.3. In the notation of Theorem 4.1, the maps $\Delta_R$ and $\Delta_L$ are injective. One can see this as follows. Let $\varepsilon : U(\mathfrak{gl}_t) \rightarrow \mathbb{C}$ be the homomorphism with $\varepsilon(\hat{e}_{i,j}) = 0$ for $1 \leq i, j \leq t$. By definition, $Y_n(\sigma)$ and $Y_n(\hat{\sigma})$ are subalgebras of the Yangian with $Y_n(\sigma) \subseteq Y_n(\hat{\sigma})$. Now the point is that the compositions $(\text{id} \otimes \varepsilon) \circ \Delta_R$ and $(\varepsilon \otimes \text{id}) \circ \Delta_L$ coincide (when defined) with the natural embedding $Y_n(\sigma) \hookrightarrow Y_n(\hat{\sigma})$.

5. The canonical filtration

In this section, we introduce another important filtration of the shifted Yangian. It is easiest to start with the Yangian $Y_n$ itself defined by the RTT presentation as in (3). The canonical filtration $F_0 Y_n \subseteq F_1 Y_n \subseteq \cdots$ of $Y_n$ is defined by declaring that the generators $T_{i,j}^{(r)}$ are all of degree $r$, i.e. $F_d Y_n$ is the span of all monomials in these generators of total degree $\leq d$. It is obvious from the relations (5.1) that the associated graded algebra $\text{gr} Y_n$ is commutative.

Suppose instead that we are given a shape $\nu = (\nu_1, \ldots, \nu_m)$. Using the explicit definitions from (6.1)–(6.4), one checks that the parabolic generators $D_{a,i,j}^{(r)}$, $E_{a,b,i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ of $Y_n$ are linear combinations of monomials in the $T_{i,j}^{(s)}$ of total degree $r$ and conversely, if we define $D_{a,i,j}^{(r)}$, $E_{a,b;i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ all to be of degree $r$, each $T_{i,j}^{(s)}$ is a linear combination of monomials in these elements of total degree $s$. Hence $F_d Y_n$ can also be described as the span of all monomials in the elements $D_{a,i,j}^{(r)}$, $E_{a,b,i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ of total degree $\leq d$. For $1 \leq a, b \leq m$, $1 \leq i \leq \nu_a$, $1 \leq j \leq \nu_b$ and $r > 0$, define

$$e_{a,b;i,j}^{(r)} := \begin{cases} \text{gr}_r D_{a,i,j}^{(r)} & \text{if } a = b, \\ \text{gr}_r E_{a,b;i,j}^{(r)} & \text{if } a < b, \\ \text{gr}_r F_{b,a;i,j}^{(r)} & \text{if } a > b, \end{cases}$$

all elements of $\text{gr}_r Y_n$. Of course, this notation depends implicitly on the fixed shape $\nu$. The commutativity of $\text{gr}_r Y_n$ together with Theorem 3.2(iv) imply:

Theorem 5.1. For any shape $\nu = (\nu_1, \ldots, \nu_m)$, $\text{gr}_r Y_n$ is the free commutative algebra on generators $\{e_{a,b;i,j}^{(r)}\}_{1 \leq a, b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, r > 0}$.

Now consider the shifted Yangian. So let $\sigma = (s_{i,j})_{1 \leq i, j \leq n}$ be a shift matrix as in (2). Viewing $Y_n(\sigma)$ as a subalgebra of $Y_n$, introduce the canonical filtration $F_0 Y_n(\sigma) \subseteq F_1 Y_n(\sigma) \subseteq \cdots$ of $Y_n(\sigma)$ by defining $F_d Y_n(\sigma) := Y_n(\sigma) \cap F_d Y_n$. Thus, the inclusion of
$Y_*(\sigma)$ into $Y_*$ is filtered and the induced map $\text{gr} Y_*(\sigma) \to \text{gr} Y_*$ is injective. Hence, $\text{gr} Y_*(\sigma)$ is identified with a subalgebra of the commutative algebra $\text{gr} Y_*$. The following theorem describes this subalgebra explicitly.

**Theorem 5.2.** For an admissible shape $\nu = (\nu_1, \ldots, \nu_m)$, $\text{gr} Y_*(\sigma)$ is the subalgebra of $\text{gr} Y_*$ generated by the elements \( \{ e_{a,b;i,j}^{(r)} \}_{1 \leq a,b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, r > s_{a,b}(\nu) \} \).

*Proof.* Note in view of the relations (3.9)–(3.10) that the element $e_{a,b;i,j}^{(r)}$ of $\text{gr} Y_*(\sigma)$ is identified with the element of the same name in $\text{gr} Y_*$. Given this the theorem follows directly from Theorems 4.1 and 5.2(iv).

**Remark 5.3.** Theorem 5.2 means that, given an admissible shape $\nu$, we can define the canonical filtration on $Y_*(\sigma)$ intrinsically simply by declaring that the elements $D_{a,b;i,j}^{(r)}$, $E_{a,b;i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ of $Y_*(\sigma)$ are all of degree $r$, i.e. $F_d Y_*(\sigma)$ is the span of all monomials in these elements of total degree $\leq d$. In particular, this definition is independent of the particular choice of admissible shape $\nu$.

**Remark 5.4.** The comultiplication $\Delta : Y_* \to Y_* \otimes Y_*$ is a filtered map with respect to the canonical filtration, as follows immediately from (4.1). Similarly, the baby comultiplications $\Delta_n : Y_n(\sigma) \to Y_n(\sigma) \otimes U(\mathfrak{gl}_t)$ and $\Delta_L : Y_n(\sigma) \to U(\mathfrak{gl}_t) \otimes Y_n(\sigma)$ from Theorem 4.1 are filtered maps whenever they are defined, providing we extend the canonical filtration of $Y_n(\sigma)$ to $Y_n(\sigma) \otimes U(\mathfrak{gl}_t)$ and $U(\mathfrak{gl}_t) \otimes Y_n(\sigma)$ by declaring that the matrix units $e_{i,j} \in \mathfrak{gl}_t$ are of degree 1. This follows from Theorem 4.1 and Lemma 4.2.

The argument explained in Remark 5.3 shows moreover that the associated graded maps $\text{gr} \Delta_n$ and $\text{gr} \Delta_L$ are injective.

6. **Truncation**

Continue with a fixed shift matrix $\sigma = (s_{i,j})_{1 \leq i,j \leq n}$. Fix also an integer $l \geq s_{1,n} + s_{n,1}$ (the "level"), and for $i = 1, \ldots, n$ let

$$p_i := l - s_{i,n} - s_{n,i},$$

(6.1)

thus defining a tuple $(p_1, \ldots, p_n)$ of integers with $0 \leq p_1 \leq \cdots \leq p_n = l$. If $\nu = (\nu_1, \ldots, \nu_m)$ is an admissible shape, we will also use the shorthand

$$p_a(\nu) := p_{\nu_1} + \cdots + p_{\nu_a}$$

(6.2)

for each $a = 1, \ldots, m$; cf. (3.2). (A better way to keep track of all this data will be explained in the next section.)

The *shifted Yangian of level* $l$, denoted $Y_{n,l}(\sigma)$, is defined to be the quotient of $Y_*(\sigma)$ by the two-sided ideal generated by the elements $\{ D_{1}^{(r)} \}_{r > p_1}$. Alternatively, in terms of the parabolic presentation relative to an admissible shape $\nu = (\nu_1, \ldots, \nu_m)$, $Y_{n,l}(\sigma)$ is the quotient of $Y_*(\sigma)$ by the two-sided ideal generated by the elements $\{ D_{i,j}^{(r)} \}_{1 \leq i,j \leq \nu_1, r > p_1}$. The equivalence of all these definitions is easy to see since $D_{1}^{(r)} = D_{1}^{(1)}$ and all other $D_{i,j}^{(r)}$ for $r > p_1$ and $1 \leq i,j \leq \nu_1$ obviously lie in the two-sided ideal generated by $\{ D_{1,1}^{(r)} \}_{r > p_1}$ in view of the relation (3.3). For example, in the case that $\sigma$ is the zero matrix, when we denote $Y_{n,l}(\sigma)$ simply by $Y_{n,l}$, this algebra is the quotient of $Y_n$ by the two-sided ideal generated by $\{ T_{i,j}^{(r)} \}_{1 \leq i,j \leq n, r > l}$, which is precisely the definition of the *Yangian of level* $l$ from [C2].
In the hope that it is clear from context whether we are talking about $Y_n(\sigma)$ or $Y_{n,l}(\sigma)$, we will abuse notation and use the same symbols $D_{a;i,j}^{(r)}$, $\bar{D}_{a;i,j}^{(r)}$, $E_{a,b;i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ both for the generators of $Y_n(\sigma)$ and for their canonical images in the quotient $Y_{n,l}(\sigma)$. The anti-isomorphism $\tau$ from (2.10) factors through the quotients to induce an anti-isomorphism

$$\tau : Y_{n,l}(\sigma) \rightarrow Y_{n,l}(\sigma').$$

(6.3)

Similarly, given another shift matrix $\hat{\sigma}$ such that $\hat{s}_{i,i+1} = s_{i,i+1} + s_{i+1,i}$ for each $i = 1, \ldots, n - 1$, the isomorphism $\iota$ from (2.17) induces an isomorphism

$$\iota : Y_{n,l}(\sigma) \rightarrow Y_{n,l}(\hat{\sigma}).$$

(6.4)

So the isomorphism type of the algebra $Y_{n,l}(\sigma)$ only actually depends on the tuple $(p_1, \ldots, p_n)$.

We will exploit the canonical filtration $F_0Y_{n,l}(\sigma) \subseteq F_1Y_{n,l}(\sigma) \subseteq \cdots$ of $Y_{n,l}(\sigma)$ induced by the quotient map $Y_n(\sigma) \rightarrow Y_{n,l}(\sigma)$ and the canonical filtration of $Y_n(\sigma)$ from [5]. Recalling Remark 5.3 this may be defined directly given an admissible shape $\nu = (\nu_1, \ldots, \nu_m)$ by declaring all the elements $D_{a;i,j}^{(r)}$, $E_{a,b;i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ of $Y_{n,l}(\sigma)$ to be of degree $r$, and then $F_dY_{n,l}(\sigma)$ is the span of all monomials in these elements of total degree $\leq d$. For $1 \leq a, b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b$ and $r > s_{a,b}(\nu)$, define elements $e_{a,b;i,j}^{(r)}$ of the associated graded algebra $\text{gr} Y_{n,l}(\sigma)$ by the formula (5.1). Since $\text{gr} Y_{n,l}(\sigma)$ is a quotient of $\text{gr} Y_n(\sigma)$, Theorem 3.2 implies that it is commutative and is generated by all $\{e_{a,b;i,j}^{(r)}\}_{1 \leq a, b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, r > s_{a,b}(\nu)}$.

**Lemma 6.1.** For any admissible shape $\nu = (\nu_1, \ldots, \nu_m)$, $\text{gr} Y_{n,l}(\sigma)$ is generated just by the elements $\{e_{a,b;i,j}^{(r)}\}_{1 \leq a, b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) < r \leq s_{a,b}(\nu) + p_{\nu}(a,b)}$.

**Proof.** For $1 \leq c \leq m$, let $\Omega_c$ denote the set

$$\{D_{a;i,j}^{(r)}\}_{1 \leq a \leq c, 1 \leq i,j \leq \nu_a, 0 < r \leq p_a(\nu)} \cup \{E_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq c, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) < r \leq s_{a,b}(\nu) + p_a(\nu)}$$

$$\cup \{F_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq c, 1 \leq j \leq \nu_b, 1 \leq i \leq \nu_a, r > s_{a,b}(\nu) + p_a(\nu)},$$

and let $\hat{\Omega}_c$ denote

$$\{D_{a;i,j}^{(r)}\}_{1 \leq a \leq c, 1 \leq i,j \leq \nu_a, r > 0} \cup \{E_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq c, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, r > s_{a,b}(\nu)}$$

$$\cup \{F_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq c, 1 \leq j \leq \nu_b, 1 \leq i \leq \nu_a, r > s_{a,b}(\nu)}.$$
Next, we have by the relations that
\[
E^{(r)}_{c-1;i,j} = [D^{(r-s_{e,c-1},c)}_{c-1;i,i}, E^{(s_{e,c-1},c)(ν)+1}_{c-1;i,j}] - \sum_{t=1}^{r-s_{e,c-1},c} \sum_{h=1}^{ν-1} D^{(t)}_{c-1;i,h} E^{(r-t)}_{c-1;h,j}. \tag{6.5}
\]

By induction, \(D^{(r-s_{e,c-1},c)(ν)}\) is a linear combination of monomials in the elements of \(Ω_{c-1}\) of total degree \((r - s_{e,c-1},c)(ν)\). Hence by the relations, the first term on the right hand side of \(6.5\) is a linear combination of monomials in the elements of \(Ω_{c-1} \cup \{E^{(r)}_{a,c,i,j}\}_{1≤a<c,1≤i≤ν_a,1≤j≤ν_c,v_a,c(ν)<r≤s_{a,c}(ν)+p_0(ν)}\) of total degree \(r\). Now using \(6.5\) and induction on \(r\), one deduces that each \(E^{(r)}_{c-1;i,j}\) is a linear combination of monomials in the elements of \(Ω_c\) of total degree \(r\). A similar argument shows that each \(E^{(r)}_{c-1;i,j}\) is a linear combination of monomials in the elements of \(Ω_c\) of total degree \(r\), too.

Finally we must consider \(D^{(r)}_{c;i,j}\). Recall that \(p_c(ν) = p_{c-1}(ν) + s_{e,c-1}(ν) + s_{c,c-1}(ν)\). By the relations, we have for \(1 ≤ k ≤ ν_c-1\) that
\[
D^{(r)}_{c;i,j} = \sum_{t=0}^{r-1} \bar{D}^{(r-t)}_{c-1;k,k} D^{(t)}_{c;i,j} - [E^{(r-s_{c,c-1},c)(ν)}_{c-1;i,j}, E^{(s_{c,c-1},c)(ν)+1}_{c-1;i,j}], \tag{6.6}
\]

By the previous paragraph, \(E^{(r-s_{c,c-1},c)(ν)}_{c-1;i,j}\) is a linear combination of monomials in the elements from \(Ω_{c-1} \cup \{E^{(r)}_{a,c,i,j}\}_{1≤a<c,1≤i≤ν_a,1≤j≤ν_c,v_a,c(ν)<r≤s_{a,c}(ν)+p_0(ν)}\) of total degree \((r - s_{c,c-1},c)(ν)\). Hence by the relations, the second term on the right hand side of \(6.6\) is a linear combination of monomials in the elements of \(Ω_c\) of total degree \(r\). Now using \(6.6\) and induction on \(r\) one deduces that each \(D^{(r)}_{c;i,j}\) is a linear combination of monomials in the elements of \(Ω_c\) of total degree \(r\), to complete the induction step. \(\Box\)

Assume additionally for the next paragraph that the level \(l > 0\). Let \(t ∈ \{1, \ldots, n\}\) be maximal such that \(s_{i,j} = 0\) for all \(n - t + 1 ≤ i, j ≤ n\). If either \(t = n\) or \(s_{n-t,n-t+1} ≠ 0\), it is easy to check that the baby comultiplication \(Δ_R\) from Theorem 4.1(i) factors through the quotients to induce a map
\[
Δ_R : Y_{n,l}(σ) \to Y_{n,l-1}(σ) ⊗ U(gl), \tag{6.7}
\]
where \(σ\) is as in \(4.5\). Similarly, if either \(t = n\) or \(s_{n-t,n-t} ≠ 0\), the baby comultiplication \(Δ_L\) from Theorem 4.1(ii) induces a map
\[
Δ_L : Y_{n,l}(σ) \to U(gl) ⊗ Y_{n,l-1}(σ), \tag{6.8}
\]
where \(σ\) is as in \(4.6\). Recalling Remark 5.4 these maps \(Δ_R\) and \(Δ_L\) are filtered, so induce homomorphisms
\[
\text{gr} Δ_R : \text{gr} Y_{n,l}(σ) \to \text{gr}(Y_{n,l-1}(σ) ⊗ U(gl)), \tag{6.9}
\]
\[
\text{gr} Δ_L : \text{gr} Y_{n,l}(σ) \to \text{gr}(U(gl) ⊗ Y_{n,l-1}(σ)) \tag{6.10}
\]
of graded algebras.

**Theorem 6.2.** For any admissible shape \(ν = (ν_1, \ldots, ν_m)\), \(\text{gr} Y_{n,l}(σ)\) is the free commutative algebra on generators \(\{E^{(r)}_{a,b,i,j}\}_{1≤a,b≤m,1≤i≤ν_a,1≤j≤ν_b,v_a,b(ν)<r≤s_{a,b}(ν)+p_{\min(a,b)}(ν)}\). Moreover, the maps \(\text{gr} Δ_R\) and \(\text{gr} Δ_L\) from \(6.7\) and \(6.8\) are injective whenever they are defined, hence so are the maps \(6.7\) and \(6.8\).
Proof. We proceed by induction on the level $l$, the case $l = 0$ being trivial. Now suppose that $l > 0$ and that the first statement of the theorem has been proved for all smaller $l$. In view of Lemma 6.1 it suffices to check the induction step in the special case that $\nu = (\nu_1, \ldots, \nu_m)$ is the minimal admissible shape for $\sigma$. At least one of the maps $\Delta_R$ or $\Delta_L$ is always defined. We will assume without loss of generality that $\Delta_R$ is defined; the theorem in the other case can be deduced from this one using the anti-isomorphism $\tau$. Introduce the following elements of $\text{gr}(Y_{n,l-1}(\hat{\sigma}) \otimes U(\mathfrak{gl}_t))$:

\[
\hat{e}^{(r)}_{a,b;i,j} := \begin{cases} 
\text{gr}_r D^{(r)}_{a;i,j} \otimes 1 & \text{if } a = b, \\
\text{gr}_r E^{(r)}_{a,b;i,j} \otimes 1 & \text{if } a < b, \\
\text{gr}_r F^{(r)}_{a,b;i,j} \otimes 1 & \text{if } a > b.
\end{cases}
\]

Also let $x_{i,j} := \text{gr}_1 \otimes e_{i,j}$ for $1 \leq i, j \leq t$. By Theorem 4.1(i), Lemma 4.2(i) and Lemma 6.1 there exist polynomials $f^{(r)}_{a;i,j}$ in all the variables $e^{(r)}_{a,b;i,j}$ such that $\text{gr} \Delta_R$ maps

\[
e^{(r)}_{a,b;i,j} \mapsto \hat{e}^{(r)}_{a,b;i,j}
\]

for $1 \leq a \leq m, 1 \leq b < m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b$ and $s_{a,b}(<r) < s_{a,b}(\nu) + r \leq s_{a,b}(\nu) + p_{\min(a,b)}(\nu)$, and

\[
e^{(r)}_{a,m;i,j} \mapsto \sum_{k=1}^{t} \hat{e}^{(r-1)}_{a,m;i,k} x_{k,j} + f^{(r)}_{a;i,j}
\]

for $1 \leq a \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_m$ and $s_{a,m}(\nu) < s_{a,m}(\nu) + p_{a}(\nu) - 1$. By the induction hypothesis and the PBW theorem for $U(\mathfrak{gl}_t)$, the elements

\[
\{x_{i,j}\}_{1 \leq i, j \leq t} \\
\{\hat{e}^{(r)}_{a,b;i,j}\}_{1 \leq a \leq m, 1 \leq b < m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(<r) \leq s_{a,b}(\nu) + p_{\min(a,b)}(\nu)} \\
\{\hat{e}^{(r)}_{a,m;i,j}\}_{1 \leq a \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_m, s_{a,m}(\nu) + \delta_{a,m-1} < r \leq s_{a,m}(\nu) + p_{a}(\nu) - 1}
\]

are algebraically independent in $\text{gr}(Y_{n,l-1}(\hat{\sigma}) \otimes U(\mathfrak{gl}_t))$. Using this and (6.11)–(6.12), one verifies explicitly that the images of the generators

\[
\{D^{(r)}_{a;i,j}\}_{1 \leq a \leq m, 1 \leq i, j \leq \nu_a, 0 < r \leq p_a(\nu)} \\
\{E^{(r)}_{a,b;i,j}\}_{1 \leq a < b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) < s_{a,b}(<r) + p_a(\nu)} \\
\{F^{(r)}_{a,b;i,j}\}_{1 \leq a < b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) + p_{\min(a,b)}(\nu) < r \leq s_{a,b}(\nu) + p_{a}(\nu)}
\]

of $\text{gr} Y_{n,l}(\sigma)$ from Lemma 6.1 under the map $\text{gr} \Delta_R$ are algebraically independent in $\text{gr} Y_{n,l-1}(\hat{\sigma}) \otimes U(\mathfrak{gl}_t)$. Hence $\Delta_R$ is injective and these generators must already be algebraically independent in $\text{gr} Y_{n,l}(\sigma)$. This completes the proof of the induction step. \hfill \Box

Corollary 6.3. For any admissible shape $\nu = (\nu_1, \ldots, \nu_m)$, the monomials in the elements

\[
\{D^{(r)}_{a;i,j}\}_{1 \leq a \leq m, 1 \leq i, j \leq \nu_a, 0 < r \leq p_a(\nu)} \\
\{E^{(r)}_{a,b;i,j}\}_{1 \leq a < b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) < s_{a,b}(\nu) + p_a(\nu)} \\
\{F^{(r)}_{a,b;i,j}\}_{1 \leq a < b \leq m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_b, s_{a,b}(\nu) + p_{\min(a,b)}(\nu) < r \leq s_{a,b}(\nu) + p_a(\nu)}
\]

taken in any fixed order form a basis for $Y_{n,l}(\sigma)$. 

\[\text{(6.12)}\]
Remark 6.4. Obviously by their definition there is an inverse system
\[ Y_{n,l}(\sigma) \leftarrow Y_{n,l+1}(\sigma) \leftarrow Y_{n,l+2}(\sigma) \leftarrow \cdots \]
Moreover, the maps are homomorphisms of filtered algebras with respect to the canonical filtrations. Comparing the basis theorems proved in Corollary 6.3 and Theorem 3.2(iv), it follows that
\[ Y_n(\sigma) = \lim_{\leftarrow} Y_{n,l}(\sigma) \]
where the inverse limit is taken in the category of filtered algebras. Hence we can view the shifted Yangian \( Y_n(\sigma) \) as the limiting case \( l \to \infty \) of the shifted Yangian \( Y_{n,l}(\sigma) \) of level \( l \).

7. Pyramids

In this section we introduce the combinatorics of pyramids. (In the more general language of [EK, §4] the things we call pyramids here should be called even pyramids.) Suppose to start with that we are given a tuple \( (q_1, q_2, \ldots, q_l) \) of positive integers. We associate a diagram \( \pi \) consisting of \( q_1 \) bricks stacked in the first (leftmost) column, \( q_2 \) bricks stacked in the second column, \( \ldots, q_l \) bricks stacked in the \( l \)th (rightmost) column. For instance if \( l = 4 \) and \( (q_1, q_2, q_3, q_4) = (4, 2, 3, 3) \), then
\[
\begin{array}{cccc}
1 & & & \\
2 & 7 & 10 & \\
3 & 5 & 8 & 11 \\
4 & 6 & 9 & 12
\end{array}
\]
Call \( \pi \) a pyramid of level \( l \) and height \( \max(q_1, \ldots, q_l) \) if each row of the diagram consists of a single connected horizontal strip. Equivalently, \( \pi \) is a pyramid if the sequence \( (q_1, q_2, \ldots, q_l) \) of column heights is a unimodal sequence, i.e.
\[ 0 < q_1 \leq \cdots \leq q_k, \quad q_{k+1} \geq \cdots \geq q_l > 0 \quad (7.1) \]
for some \( 0 \leq k \leq l \). Of course, the above diagram is not a pyramid, since there is a gap between the entries 2 and 7.

Given a diagram \( \pi \) (not necessarily a pyramid), we pick an integer \( n \geq \max(q_1, \ldots, q_l) \) and number the rows of the diagram \( 1, 2, \ldots, n \) from top to bottom. Let \( p_i \) denote the number of bricks in the \( i \)th row, thus defining the tuple \( (p_1, \ldots, p_n) \) of row lengths with
\[ 0 \leq p_1 \leq \cdots \leq p_n = l. \quad (7.2) \]
Fix also some numbering of the bricks of the diagram by \( 1, 2, \ldots, N \). Usually we have in mind the numbering down columns from left to right as in the above example but any bijective numbering will do. For \( i = 1, \ldots, N \), let \( \text{row}(i) \) and \( \text{col}(i) \) denote the row and column numbers of the brick in which \( i \) appears, respectively.

Now let \( g \) denote the Lie algebra \( \mathfrak{gl}_N \) over \( \mathbb{C} \) and introduce a \( \mathbb{Z} \)-grading \( g = \bigoplus_{j \in \mathbb{Z}} g_j \) of \( g \) by declaring that the \( ij \)-matrix unit \( e_{i,j} \) is of degree \( (\text{col}(j) - \text{col}(i)) \). Let
\[ p := \bigoplus_{j \geq 0} g_j, \quad h := g_0, \quad m := \bigoplus_{j < 0} g_j. \quad (7.3) \]
Thus \( p \) is a parabolic subalgebra of \( g \) with Levi factor \( h \cong \mathfrak{gl}_{q_1} \oplus \cdots \oplus \mathfrak{gl}_{q_l} \), and \( m \) is the nilradical of the opposite parabolic to \( p \) with respect to \( h \). Let \( P, H \) and \( M \) be the
corresponding closed subgroups of the algebraic group $G := GL_N$ over $\mathbb{C}$. Also let

$$e := \sum_{1 \leq i,j \leq N \atop \text{row}(i) = \text{row}(j) \atop \text{col}(i) = \text{col}(j) - 1} e_{i,j}.$$  \hspace{1cm} (7.4)

By a dimension calculation, one checks that $e$ belongs to the unique dense orbit of $H$ on $\mathfrak{g}_1$, regardless of whether the diagram $\pi$ is a pyramid or not. Moreover, the Jordan block sizes of the matrix $e$ are precisely the lengths of the maximal connected horizontal strips in the diagram $\pi$, hence $e$ is of Jordan type $(p_1, \ldots, p_n)$ if and only if the diagram $\pi$ is a pyramid.

Recall from [Ca, §5.2] that an element $e$ of the nilradical of $\mathfrak{p}$ is called a Richardson element for $\mathfrak{p}$ if its orbit under the adjoint action of $P$ is dense in the nilradical of $\mathfrak{p}$; equivalently,

$$\dim c_{\mathfrak{g}}(e) = \dim \mathfrak{h}. \hspace{1cm} (7.5)$$

By another dimension calculation (as observed originally by Kraft [Kr]) the Jordan type of a Richardson element for $\mathfrak{p}$ is given by the row lengths $(p_1, \ldots, p_n)$ of the diagram $\pi$, again regardless of whether $\pi$ is a pyramid or not. We say that $\mathfrak{p}$ is a good parabolic if $\mathfrak{g}_1$ contains a Richardson element for $\mathfrak{p}$. Such an element $e$ then clearly belongs both to the dense orbit of $P$ on the nilradical of $\mathfrak{p}$ and to the dense orbit of $H$ on $\mathfrak{g}_1$. Hence up to conjugacy, we may assume that $e$ given by (7.4). Since its Jordan type must also be $(p_1, \ldots, p_n)$, we obtain the following special case of [L, Lemma 7.2]:

**Theorem 7.1.** $\mathfrak{p}$ is a good parabolic if and only if the diagram $\pi$ is a pyramid.

**Remark 7.2.** In view of [EK, Theorem 2.1], this theorem implies that there is a bijective map from pyramids to conjugacy classes of even good gradings of $\mathfrak{g} = \mathfrak{gl}_N$, as defined in the introduction. The map sends a pyramid $\pi$ to twice the grading defined here, which is an even good grading for the nilpotent matrix $e$ defined by (7.4).

To make the connection with the earlier sections, we point out that pyramids provide an extremely convenient way to visualize the data needed to define the shifted Yangian $Y_{n,l}(\sigma)$ of level $l$. Indeed, given a shift matrix $\sigma = (s_{i,j})_{1 \leq i,j \leq n}$ and a level $l \geq s_{1,n} + s_{n,1}$, we define $(p_1, \ldots, p_n)$ from $p_i := l - s_{i,n} - s_{n,i}$ like in (6.1). Now draw a pyramid $\pi$ with $p_i$ bricks on the $i$th row indented $s_{n,i}$ columns from the left hand edge and $s_{i,n}$ columns from the right hand edge, for each $i = 1, \ldots, n$. Conversely, given a pyramid $\pi$ of height $\leq n$, define a shift matrix $\sigma = (s_{i,j})_{1 \leq i,j \leq n}$ from the equation

$$s_{i,j} = \begin{cases} \# \{ c = 1, \ldots, k \mid i > n - q_c \geq j \} & \text{if } i \geq j, \\ \# \{ c = k + 1, \ldots, l \mid i \leq n - q_c < j \} & \text{if } i \leq j, \end{cases} \hspace{1cm} (7.6)$$

where $(q_1, \ldots, q_l)$ are the column heights and $k$ is chosen as in (7.1). This definition is independent of the choice of $k$ only if the pyramid $\pi$ is of height exactly $n$, in which case $s_{i,j}$ is simply the number of bricks the $i$th row is indented from the $j$th row at the left edge of the diagram if $i \geq j$, at the right edge of the diagram if $i \leq j$. For example,

$$l = 7, \sigma = \begin{pmatrix} 0 & 1 & 1 & 3 \\ 0 & 0 & 0 & 2 \\ 1 & 1 & 0 & 2 \\ 2 & 2 & 1 & 0 \end{pmatrix} \quad \leftrightarrow \quad n = 4, \pi = \begin{array}{cccccccccccccccc} & & & & & & & & & & & & & & & & \\ & & & & & & & & & & & & & & & & \\ & & & & & & & & & & & & & & & & \\ & & & & & & & & & & & & & & & & \\ \end{array}$$
Now we have a convenient notation to record the explicit description of the centralizer $c_{\tilde{\mathfrak{g}}}(e)$ of the nilpotent element $e$ associated to a pyramid $\pi$; see [SS IV.1.6].

**Lemma 7.3.** Let $\pi$ be a pyramid of height $\leq n$ with row lengths $(p_1, \ldots, p_n)$ and associated shift matrix $\sigma = (s_{i,j})_{1 \leq i, j \leq n}$, and let $e$ be the nilpotent matrix defined by (7.4). For $1 \leq i, j \leq n$ and $r \geq 0$, let

$$c_{i,j}^{(r)} := \sum_{\substack{1 \leq h, k \leq N \\row(h) = i, \row(k) = j \\col(k) - \col(h) + 1 = r}} c_{h,k}.$$ 

Then, the vectors $\{c_{i,j}^{(r)} \}_{1 \leq i, j \leq n, s_{i,j} < r} \cup \{p_{\text{min}(i,j)} \}$ give a basis for $c_{\tilde{\mathfrak{g}}}(e)$.

8. Finite $W$-algebras

Continue with $g = g_1$ and $G = GL_N$ acting on $g$ by the adjoint action $\text{Ad}$. Fixing a pyramid $\pi$ with bricks numbered $1, \ldots, N$, we have the associated $\mathbb{Z}$-grading on $g$ as in (7) so that $c_{i,j}$ is of degree $\text{col}(j) - \text{col}(i)$. Also define $p, h, m$ and the nilpotent matrix $e \in g_1$ according to (7.3)–(7.4). Define $h \in g_0$ and $f \in g_1$ to be the unique matrices so that $(e, h, f)$ is an $\mathfrak{sl}_2$-triple in $g$. Let $m$ and $p$ denote the orthogonal complements of $m$ and $p$ with respect to the trace form $(\cdot, \cdot)$ on $g$, i.e.

$$m = \bigoplus_{j \leq 0} g_j \text{ and } p = \bigoplus_{j > 0} g_j.$$ 

**Lemma 8.1.** In the above notation,

(i) $m = [m, e] \oplus c_{\tilde{\mathfrak{g}}}(f)$;
(ii) $p = [p, f] \oplus c_{\tilde{\mathfrak{g}}}(e)$;
(iii) $c_{\tilde{\mathfrak{g}}}(f) = m \oplus [p, f]$.

**Proof.** Since $e$ is a Richardson element for $p$, we know that $\dim c_{\tilde{\mathfrak{g}}}(e) = \dim h$ and $c_{\tilde{\mathfrak{g}}}(e) \subseteq p$. Hence the map $m \to [m, e], x \mapsto [x, e]$ is a bijection. Similarly, $\dim c_{\tilde{\mathfrak{g}}}(f) = \dim h$ and $c_{\tilde{\mathfrak{g}}}(f) \subseteq m$. Hence the map $p \to [p, f], y \mapsto [y, f]$ is a bijection. So

$$\dim [m, e] + \dim c_{\tilde{\mathfrak{g}}}(f) = \dim m + \dim h = \dim m,$$

$$\dim [p, f] + \dim c_{\tilde{\mathfrak{g}}}(e) = \dim p + \dim h = \dim p.$$ 

Also by $\mathfrak{sl}_2$ theory, $[m, e] \cap c_{\tilde{\mathfrak{g}}}(f) = [p, f] \cap c_{\tilde{\mathfrak{g}}}(e) = 0$. Parts (i) and (ii) follow. For (iii), we have that

$$\dim m + \dim [p, f] = \dim g - \dim h = \dim c_{\tilde{\mathfrak{g}}}(f),$$

and clearly $m \cap [p, f] = 0$, so we just have to check that $m \subseteq c_{\tilde{\mathfrak{g}}}(f)$ and that $[p, f] \subseteq c_{\tilde{\mathfrak{g}}}(f)$. The former statement is true since $c_{\tilde{\mathfrak{g}}}(f) \subseteq m$. For the latter, note for any $x \in p$ and $y \in c_{\tilde{\mathfrak{g}}}(f)$ that $([x, f], y) = (x, [f, y]) = 0$ by the invariance of the trace form.

To recall the definition of the algebra $W(\pi)$ from the introduction, let $\chi : m \to C$ denote the representation mapping $x \mapsto (x, e)$ for each $x \in m$. Let $I_x$ denote the kernel of the corresponding algebra homomorphism $U(m) \to C$ and $\text{pr}_\chi : U(g) \to U(p)$ be the projection along the direct sum decomposition

$$U(g) = U(p) \oplus U(g)I_x.$$ 

(8.1)
For \( x \in \mathfrak{m} \) and \( y \in U(\mathfrak{p}) \), we set \( x \cdot y := \text{pr}_\chi([x, y]) = \text{pr}_\chi(xy) - \chi(x)y \), to define the twisted action of \( \mathfrak{m} \) on \( U(\mathfrak{p}) \). Then, the finite \( W \)-algebra \( W(\pi) \) associated to the pyramid \( \pi \) is the space \( U(\mathfrak{p})^m \) of twisted \( \mathfrak{m} \)-invariants in \( U(\mathfrak{p}) \). Equivalently,

\[
W(\pi) = \{ y \in U(\mathfrak{p}) \mid (x - \chi(x))y \in U(\mathfrak{g})I_\chi \text{ for all } x \in \mathfrak{m} \},
\]

from which it follows easily that \( W(\pi) \) is actually a subalgebra of \( U(\mathfrak{p}) \). For example, in the special case that \( \pi \) consists of a single column, we obviously have that \( \mathfrak{p} = \mathfrak{g} \), \( m = 0 \) and \( e = 0 \), hence \( W(\pi) = U(\mathfrak{g}_N) \).

We need the Kazhdan filtration \( \cdots \subseteq F_dU(\mathfrak{g}) \subseteq F_{d+1}U(\mathfrak{g}) \subseteq \cdots \) of \( U(\mathfrak{g}) \) defined by declaring that the generator \( e_{i,j} \) is of degree

\[
\deg(e_{i,j}) := \col(j) - \col(i) + 1
\]

for each \( 1 \leq i, j \leq N \), i.e. \( F_dU(\mathfrak{g}) \) is spanned by all monomials \( e_{i_1,j_1} \cdots e_{i_m,j_m} \) for \( m \geq 0 \) and \( \deg(e_{i_1,j_1}) + \cdots + \deg(e_{i_m,j_m}) \leq d \). The adjoint action of \( \mathfrak{g} \) on \( U(\mathfrak{g}) \) is filtered in the sense that \( [\mathfrak{g}_j, F_dU(\mathfrak{g})] \subseteq F_{d+1}U(\mathfrak{g}) \) for each \( j, d \in \mathbb{Z} \). Hence the associated graded algebra \( \text{gr} \ U(\mathfrak{g}) \) is naturally a graded \( \mathfrak{g} \)-module. Of course by the PBW theorem we can identify \( \text{gr} \ U(\mathfrak{g}) \) with the symmetric algebra \( S(\mathfrak{g}) \) with the usual \( \mathfrak{g} \)-action, but viewed as a graded algebra via the Kazhdan grading also defined by (8.3).

There are induced Kazhdan filtrations of the subalgebras \( U(\mathfrak{p}) \) and \( W(\pi) \) defined by setting \( F_dU(\mathfrak{p}) := \text{pr}_\chi(F_dU(\mathfrak{g})) \) and \( F_dW(\pi) := W(\pi) \cap F_dU(\mathfrak{p}) \). This time we have that \( F_dU(\mathfrak{p}) = F_dW(\pi) = 0 \) for all \( d < 0 \). The projection \( \text{pr}_\chi : U(\mathfrak{g}) \to U(\mathfrak{p}) \) is filtered, hence so is the twisted action of \( \mathfrak{m} \) on \( U(\mathfrak{p}) \), and \( \text{gr} \text{pr}_\chi : \text{gr} U(\mathfrak{g}) \to \text{gr} U(\mathfrak{p}) \) is a graded \( \mathfrak{m} \)-module homomorphism. If we identify \( \text{gr} U(\mathfrak{p}) \) with \( S(\mathfrak{p}) \) graded via (8.3), then we can describe the map \( \text{gr} \text{pr}_\chi \) simply as the algebra homomorphism \( p : S(\mathfrak{g}) \to S(\mathfrak{p}) \) that acts as the identity on elements of \( \mathfrak{p} \) and sends \( x \in \mathfrak{m} \) to \( \chi(x) \). This explains the top left hand quadrant of the following commutative diagram:

\[
\begin{array}{ccc}
\text{gr} U(\mathfrak{g}) & \overset{\text{pr}_\chi}{\longrightarrow} & S(\mathfrak{g}) \\
\downarrow & & \downarrow_{\sim \alpha} \\
\text{gr} U(\mathfrak{p}) & \overset{p}{\longrightarrow} & S(\mathfrak{p}) \\
\downarrow & & \downarrow_{\sim \beta} \\
\text{gr} W(\pi) & \overset{\beta}{\longrightarrow} & S(\mathfrak{c}_0(e)) \overset{\sim \gamma}{\longrightarrow} \mathbb{C}[e + \mathfrak{c}_0(f)]
\end{array}
\]

To make sense of the bottom left hand quadrant, let \( i : W(\pi) \to U(\mathfrak{p}) \) be the inclusion, and let \( q : S(\mathfrak{p}) \to S(\mathfrak{c}_0(e)) \) be the algebra homomorphism induced by the projection \( \mathfrak{p} \to \mathfrak{c}_0(e) \) along the direct sum decomposition from Lemma 8.1(ii). Note both \([\mathfrak{p}^+, f] \) and \( \mathfrak{c}_0(e) \) are graded subspaces of \( \mathfrak{g} \); in the latter case one way to see this is by Lemma 7.3 since the basis element \( e_{i,j}^{(r)} \) there is clearly of degree \( r \) with respect to the Kazhdan grading. Hence the map \( q \) is a graded map. Finally let \( \theta : \text{gr} W(\pi) \to S(\mathfrak{c}_0(e)) \) be the composite \( q \circ \text{gr} i \).

Now we turn our attention to the right hand half of the diagram. Imitating [GG §2.1], let \( \gamma : \mathbb{C}^\times \to G \) be the group homomorphism defined by letting

\[
\gamma(t) := \text{diag}(t^{-\col(1)}, t^{-\col(2)}, \ldots, t^{-\col(N)}) \in GL_N
\]

(8.5)
for each $t \in \mathbb{C}^\times$. So $\text{Ad} \gamma(t)$ acts on $\mathfrak{g}_j$ by the scalar $t^j$ for each $t \in \mathbb{C}^\times$ and $j \in \mathbb{Z}$.

Introduce a linear action $\rho$ of $\mathbb{C}^\times$ on the variety $\mathfrak{g}$ by letting
\[
\rho(t)(x) := t^{-1} \text{Ad} \gamma(t)(x)
\]
for each $t \in \mathbb{C}^\times$, $x \in \mathfrak{g}$. Thus, $\rho(t)(e_{i,j}) = t^{-\deg(e_{i,j})}e_{i,j}$ for each $1 \leq i, j \leq N$. In particular, $\rho(t)(e) = e$ for every $t \in \mathbb{C}^\times$ and
\[
\lim_{t \to \infty} \rho(t)(x) = 0
\]
for all $x \in \mathfrak{m}^\perp$. We get an induced action $\tilde{\rho}$ of $\mathbb{C}^\times$ on the coordinate algebra $\mathbb{C}[\mathfrak{g}]$ with
\[
(\tilde{\rho}(t)(f))(x) = f(\rho(t^{-1})(x))
\]
for each $f \in \mathbb{C}[\mathfrak{g}]$, $x \in \mathfrak{g}$. Using this, we define a grading on $\mathbb{C}[\mathfrak{g}]$ by declaring that $f \in \mathbb{C}[\mathfrak{g}]$ is of degree $j$ if $\tilde{\rho}(t)(f) = t^j f$ for each $t \in \mathbb{C}^\times$. Since $e$ is a $\rho$-fixed point, it is easy to see that each $\rho(t)$ leaves both $e + \mathfrak{m}^\perp$ and the Slodowy slice $e + \mathfrak{c}_\theta(f)$ invariant.

So just like for $\mathbb{C}[\mathfrak{g}]$, we get induced actions $\tilde{\rho}$ of $\mathbb{C}^\times$ on the coordinate algebras $\mathbb{C}[e + \mathfrak{m}^\perp]$ and $\mathbb{C}[e + \mathfrak{c}_\theta(f)]$ which we use to introduce a grading on these algebras. The natural restriction maps $r : \mathbb{C}[\mathfrak{g}] \to \mathbb{C}[e + \mathfrak{m}^\perp]$ and $s : \mathbb{C}[e + \mathfrak{m}^\perp] \to \mathbb{C}[e + \mathfrak{c}_\theta(f)]$ are $\tilde{\rho}$-equivariant, hence are graded.

The trace form defines an isomorphism $\alpha : S(\mathfrak{g}) \to \mathbb{C}[\mathfrak{g}]$ of graded algebras. It maps the kernel of the homomorphism $p : S(\mathfrak{g}) \to S(\mathfrak{p})$ isomorphically onto the annihilator in $\mathbb{C}[\mathfrak{g}]$ of the closed subvariety $e + \mathfrak{m}^\perp$. Hence $\alpha$ induces a graded algebra isomorphism $\beta : S(\mathfrak{p}) \to \mathbb{C}[e + \mathfrak{m}^\perp]$. Similarly by Lemma 8.1(ii),(iii), $\beta$ maps the kernel of the homomorphism $q : S(\mathfrak{p}) \to S(\mathfrak{c}_\theta(e))$ isomorphically onto the annihilator in $\mathbb{C}[e + \mathfrak{m}^\perp]$ of $e + \mathfrak{c}_\theta(f)$, hence induces a graded algebra isomorphism $\gamma : S(\mathfrak{c}_\theta(e)) \to \mathbb{C}[e + \mathfrak{c}_\theta(f)]$.

To complete the picture, we need to introduce an action of the subgroup $M$ of $G$ corresponding to the subalgebra $\mathfrak{m}$ of $\mathfrak{g}$. The adjoint action of $G$ on $\mathfrak{g}$ induces an action of $G$ on $\mathbb{C}[\mathfrak{g}]$ by algebra automorphisms, such that the derived action of $\mathfrak{g}$ corresponds under the isomorphism $\alpha$ to the usual $\mathfrak{g}$-action on $S(\mathfrak{g})$. The subgroup $M$ of $G$ leaves $e + \mathfrak{m}^\perp$ invariant, hence we get induced actions of $M$ and $\mathfrak{m}$ on $\mathbb{C}[e + \mathfrak{m}^\perp]$, such that the action of $\mathfrak{m}$ agrees under the isomorphism $\beta$ with the twisted action of $\mathfrak{m}$ on $S(\mathfrak{p})$. In particular since $S(\mathfrak{p})$ is a graded $\mathfrak{m}$-module, it follows that the space $\mathbb{C}[e + \mathfrak{m}^\perp]^M = \mathbb{C}[e + \mathfrak{m}^\perp]^M$ of $\mathfrak{m}$-invariants/$M$-fixed points is a graded subalgebra of $\mathbb{C}[e + \mathfrak{m}^\perp]$. One can see this directly by introducing an action $\rho$ of $\mathbb{C}^\times$ on $M \times (e + \mathfrak{m}^\perp)$ defined by
\[
\rho(t)(m, x) := (\gamma(t)m\gamma(t)^{-1}, \rho(t)(x))
\]
for all $m \in M, x \in e + \mathfrak{m}^\perp$ and $t \in \mathbb{C}^\times$. The following calculation checks that the adjoint action $\varphi : M \times (e + \mathfrak{m}^\perp) \to e + \mathfrak{m}^\perp$ is $\rho$-equivariant:
\[
\text{Ad}(\gamma(t)m\gamma(t)^{-1})\rho(t)(x) = t^{-1} \text{Ad} \gamma(t) \text{Ad} m \text{Ad} \gamma(t)^{-1} \text{Ad} \gamma(t)(x)
\]
\[
= t^{-1} \text{Ad} \gamma(t) \text{Ad} m(x) = \rho(t)(\text{Ad} m(x)).
\]
This now implies that the space of $M$-fixed points in $\mathbb{C}[e + \mathfrak{m}^\perp]$ is invariant under each $\rho(t)$, hence is graded. Let us also note that
\[
\lim_{t \to \infty} (\gamma(t)m\gamma(t)^{-1}) = 1
\]
for all $m \in M$.

It just remains to prove that the composite of the inclusion $\mathbb{C}[e + \mathfrak{m}^\perp]^M \hookrightarrow \mathbb{C}[e + \mathfrak{m}^\perp]$ and the projection $s : \mathbb{C}[e + \mathfrak{m}^\perp] \to \mathbb{C}[e + \mathfrak{c}_\theta(f)]$ is an isomorphism. This follows from
the following key result, which is due originally to Kostant [K, Theorem 1.2], and is proved in this generality in [L, Theorem 1.2] using Zariski’s Main Theorem. The alternative argument sketched here is due to Gan and Ginzburg; see [GG, Lemma 2.1].

**Theorem 8.2.** The adjoint action \( \varphi : M \times (e + \mathfrak{c}_g(f)) \to e + m^\perp \) is an isomorphism of affine varieties.

**Proof.** We just verify the hypothesis needed to apply the general result from the proof of [GG, Lemma 2.1]: An equivariant morphism \( \varphi : X_1 \to X_2 \) of smooth affine \( \mathbb{C}^\times \)-varieties with contracting \( \mathbb{C}^\times \)-actions which induces an isomorphism between the tangent spaces at the \( \mathbb{C}^\times \)-fixed points must be an isomorphism. We have already defined actions \( \rho \) of \( \mathbb{C}^\times \) on \( e + m^\perp \) \((8.9)\) and on \( M \times (e + \mathfrak{c}_g(f)) \) \((8.10)\) and checked that \( \varphi \) is \( \rho \)-equivariant. By \((8.9)\) and \((8.10)\), we have that \( \lim_{t \to \infty} \rho(t)(m, x) = (1, e) \) for each \( (m, x) \in M \times (e + \mathfrak{c}_g(f)) \) and that \( \lim_{t \to \infty} \rho(t)(x) = e \) for each \( x \in e + m^\perp \). Hence the \( \mathbb{C}^\times \)-actions are both contracting. So finally we need to check that the differential \( d\varphi_{(1, e)} \) is an isomorphism between the tangent spaces \( T_{(1, e)}(M \times (e + \mathfrak{c}_g(f))) \) and \( T_e(e + m^\perp) \). But if we identify the tangent spaces with \( m \oplus \mathfrak{c}_g(f) \) and \( m^\perp \) respectively, then the differential is the map \( (x, y) \mapsto [x, e] + y \). Hence it is an isomorphism by Lemma \((9.1)\). \( \square \)

The crucial thing that we can now read off from the diagram \((8.3)\) is the following:

**Corollary 8.3.** The map \( \theta : \text{gr} W(\pi) \to S(\mathfrak{c}_g(e)) \) is an injective graded algebra homomorphism.

**Proof.** Clearly \( \text{gr} i \) maps \( \text{gr} W(\pi) \) injectively into the space of \( m \)-invariants in \( \text{gr} U(\mathfrak{p}) \). Hence, \( \beta \circ \text{gr} i \) maps \( \text{gr} W(\pi) \) into \( \mathbb{C}[e + m^\perp]^M \). Hence \( s \circ \beta \circ \text{gr} i \) is injective. But this is \( \gamma \circ \theta \) by the commutativity of the diagram, hence \( \theta \) is injective too. \( \square \)

**Remark 8.4.** It is known by [L, Theorem 2.3] that the map \( \theta \) is actually an isomorphism, hence \( \text{gr} W(\pi) \) is isomorphic to the coordinate algebra \( \mathbb{C}[e + \mathfrak{c}_g(f)] \) of the Slodowy slice as stated in the introduction. A quicker proof can also be given by following the arguments of [GG, §5]. However we do not need to use this fact yet, and we will be able deduce it later on as a consequence of the main result of the article; see Corollary \((10.2)\).

9. Invariants

In this section we define some remarkable elements of \( U(\mathfrak{p}) \), many of which will eventually turn out to be \( m \)-invariant, i.e. to belong to the subalgebra \( W(\pi) \). Letting \((q_1, \ldots, q_l)\) denote the column heights of our fixed pyramid \( \pi \), pick an integer \( n \geq \max(q_1, \ldots, q_l) \). Define \( \rho = (\rho_1, \ldots, \rho_l) \) by setting

\[
\rho_r := n - q_r - q_{r+1} - \cdots - q_l \quad (9.1)
\]

for each \( r = 1, \ldots, l \). For \( 1 \leq i, j \leq N \), define

\[
\tilde{e}_{i,j} := (-1)^{\text{col}(j) - \text{col}(i)} (e_{i,j} + \delta_{i,j} \rho_{\text{col}(i)}) \quad (9.2)
\]

so

\[
[\tilde{e}_{i,j}, \tilde{e}_{h,k}] = (\tilde{e}_{i,k} - \delta_{i,k} \rho_{\text{col}(i)}) \delta_{h,j} - \delta_{i,k} (\tilde{e}_{h,j} - \delta_{h,j} \rho_{\text{col}(j)}). \quad (9.3)
\]
Let us also spell out the effect of the homomorphism $U(m) \to \mathbb{C}$ induced by the character $\chi$: we have that
\[
\tilde{e}_{i,j} \mapsto \begin{cases} 
-1 & \text{if } \text{row}(i) = \text{row}(j) \text{ and } \text{col}(i) = \text{col}(j) + 1; \\
0 & \text{otherwise}.
\end{cases}
\] (9.4)

For $1 \leq i, j \leq n$ and signs $\sigma_1, \ldots, \sigma_n \in \{\pm\}$, we let $T^{(0)}_{i:j;\sigma_1,\ldots,\sigma_n} := \delta_{i,j}\sigma_i$ and for $r \geq 1$ define
\[
T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_n} := \sum_{s=1}^{r} \sum_{i_1, \ldots, i_s, j_1, \ldots, j_s} \sigma_{\text{row}(j_1)} \cdots \sigma_{\text{row}(j_{s-1})} \tilde{e}_{i_1,j_1} \cdots \tilde{e}_{i_s,j_s}
\] (9.5)
where the second sum is over all $1 \leq i_1, \ldots, i_s, j_1, \ldots, j_s \leq N$ such that
1. $\deg(e_{i_1,j_1}) + \cdots + \deg(e_{i_s,j_s}) = r$ (recall (8.3));
2. $\text{col}(i_t) \leq \text{col}(j_t)$ for each $t = 1, \ldots, s$;
3. if $\sigma_{\text{row}(j_t)} = +$ then $\text{col}(j_t) < \text{col}(i_{t+1})$ for each $t = 1, \ldots, s - 1$;
4. if $\sigma_{\text{row}(j_t)} = -$ then $\text{col}(j_t) \geq \text{col}(i_{t+1})$ for each $t = 1, \ldots, s - 1$;
5. $\text{row}(i_1) = i$, $\text{row}(j_s) = j$;
6. $\text{row}(j_t) = \text{row}(i_{t+1})$ for each $t = 1, \ldots, s - 1$.

Note the assumptions (1) and (2) imply that $T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_n}$ belongs to $F_rU(p)$. For $x = 0, 1, \ldots, n$, let $T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_n}$ denote $T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_n}$ in the special case that $\sigma_1 = \cdots = \sigma_x = -$, $\sigma_{x+1} = \cdots = \sigma_n = +$. Define
\[
T_{i,j;x}(u) := \sum_{r \geq 0} T^{(r)}_{i,j;x} u^{-r} \in U(p)[[u^{-1}]].
\] (9.6)
Since this is the most critical definition in the entire paper, let us give some simple examples.

**Example 9.1.** For any $1 \leq i, j \leq n$ and $x = 0, 1, \ldots, n$,
\[
T^{(1)}_{i,j;x} = \sum_{1 \leq h, k \leq N} \tilde{e}_{h,k},
\]
\[
T^{(2)}_{i,j;x} = \sum_{1 \leq h, k \leq N} \tilde{e}_{h,k} - \sum_{1 \leq h_1, k_1, k_2 \leq N} \tilde{e}_{h_1,k_1} \tilde{e}_{h_2,k_2}
\]
\[
- \sum_{1 \leq h_1, k_1, k_2 \leq N} \tilde{e}_{h_1,k_1} \tilde{e}_{h_2,k_2}
\]
\[
+ \sum_{1 \leq h_1, k_1, k_2 \leq N} \tilde{e}_{h_1,k_1} \tilde{e}_{h_2,k_2}.
\]

**Lemma 9.2.** Suppose $0 \leq x < y \leq n$.

(i) If $x < i \leq y$ and $y < j \leq n$ then
\[
T_{i,j;x}(u) = \sum_{k=x+1}^{y} T_{i,k;x}(u) T_{k,j;y}(u).
\]
(ii) If $y < i \leq n$ and $x < j \leq y$ then

$$T_{i,j;x}(u) = \sum_{k=x+1}^{y} T_{i,k;y}(u)T_{k,j;x}(u).$$

(iii) If $y < i, j \leq n$ then

$$T_{i,j;x}(u) = T_{i,j;y}(u) + \sum_{k,l=x+1}^{y} T_{i,k;y}(u)T_{k,l;x}(u)T_{l,j;y}(u).$$

(iv) If $x < i, j \leq y$ then

$$\sum_{k=x+1}^{y} T_{i,k;x}(u)T_{k,j;y}(u) = -\delta_{i,j}.$$

**Proof.** Let $\xi_{i,j} := e_{i,j}u^{-\deg(e_{i,j})}$ for short.

(i) The right hand side of the formula in (i) is a sum of monomials of the form

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}),$$

(9.7)

for various $r \geq 0, s \geq 1$, where $\pm\xi_{i_1,j_1} \cdots \xi_{i_r,j_r}$ appears in $T_{i,k;x}(u)$ and $\pm\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{k,j;y}(u)$ for some $x < k \leq y$. Let $X$ be the sum of all such monomials for which $\text{col}(j_r) < \text{col}(k_1)$ if $r > 0$ and for which $\text{row}(l_t) \notin \{x+1, \ldots, y\}$ for all $1 \leq t < s$. Let $Y$ be the sum of all remaining monomials. Thus, the right hand side of the formula in (i) is equal to $X + Y$. Now we proceed to show that $X = T_{i,j;x}(u)$ and that $Y = 0$.

First consider $X$. Take a monomial of the form (9.7) appearing in $X$, so $\text{col}(j_r) < \text{col}(k_1)$ if $r > 0$ and $\text{row}(l_t) \notin \{x+1, \ldots, y\}$ for all $1 \leq t < s$. It is easy to see that this monomial also appears in the expansion of $T_{i,j;x}(u)$, with the same sign. Moreover, the monomial (9.7) appears in $X$ exactly once: otherwise we would be able to obtain this monomial in the expansion of $X$ in another way by splitting it *either* as

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r}\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}),$$

for some $1 \leq t < s$ so that, writing $h = \text{row}(l_t)$, $\pm\xi_{i_1,j_1} \cdots \xi_{i_r,j_r}\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{i,h;x}(u)$ and $\pm\xi_{k_1,l_1+1} \cdots \xi_{k_s,l_s}$ appears in $T_{h,j;y}(u)$, or as

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_{t-1},j_{t-1}})(\xi_{i_{t-1},j_t} \cdots \xi_{i_r,j_r}\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}),$$

for some $1 \leq u < r$ so that, writing $h = \text{row}(l_u)$, $\pm\xi_{i_1,j_1} \cdots \xi_{i_{u-1},j_{u-1}} \cdots \xi_{i_r,j_r}\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{i,h;x}(u)$ and $\pm\xi_{i_{u-1},j_{u-1}} \cdots \xi_{i_r,j_r}\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{h,j;y}(u)$. The former case does not happen since we have that $h \notin \{x+1, \ldots, y\}$ by assumption. The latter case does not happen since $\text{col}(j_r) < \text{col}(k_1)$ contrary to the definition of the monomials arising in $T_{h,j;y}(u)$.

To complete the proof that $X = T_{i,j;x}(u)$, we need to show that every monomial $\pm\xi_{p_1,q_1} \cdots \xi_{p_u,q_u}$ appearing in $T_{i,j;x}(u)$ also appears in $X$. Take $r \geq 0$ to be the maximal index such that $\pm\xi_{p_1,q_1} \cdots \xi_{p_r,q_r}$ appears in $T_{i,k;x}(u)$ for some $x < k \leq y$. Such an $r$ exists as for $r = 0$ the monomial 1 appears in $T_{i,x}(u)$. It remains to observe that $\text{col}(q_r) < \text{col}(p_{r+1})$ and that $\text{row}(q_1) \notin \{x+1, \ldots, y\}$ for all $r < t < u$, for otherwise $r$ could be made bigger. In particular this means that $\pm\xi_{p_{r+1},q_{r+1}} \cdots \xi_{p_u,q_u}$ appears in $T_{k,j;y}(u)$. Hence if we split our monomial as $\pm(\xi_{p_1,q_1} \cdots \xi_{p_r,q_r})(\xi_{p_{r+1},q_{r+1}} \cdots \xi_{p_u,q_u})$, we have something of the form (9.7) that appears in $X$.

Now consider $Y$. Take a monomial of the form (9.7) appearing in $Y$, i.e. either $r > 0$ and $\text{col}(j_r) \geq \text{col}(k_1)$ or there is some $1 \leq t < s$ such that $x < \text{row}(l_t) \leq y$. We
show that this monomial appears exactly twice in the expansion of $Y$, with opposite signs. There are two cases.

Suppose first that $r > 0$ and that $\text{col}(j_r) \geq \text{col}(k_1)$. Let $t \leq r$ be the maximal index such that $x < \text{row}(i_t) \leq y$; such a $t$ exists since $\text{row}(i_1) = i$ and $x < t \leq y$. Let $h := \text{row}(i_t)$. Then the monomial $\pm \xi_{i_1,j_1} \cdots \xi_{i_{t-1},j_{t-1}}$ appears in $T_{i_1,h;x}(u)$ and the monomial $\pm \xi_{i_t,j_t} \cdots \xi_{i_{t+1},j_{t+1}} \cdots \xi_{k_s,l_s}$ appears in $T_{h,j;y}(u)$. Moreover, using the facts that $\text{col}(j_{t-1}) < \text{col}(i_t)$ if $t > 1$, $\text{col}(j_r) \geq \text{col}(k_1)$, and the maximality of the choice of $t$, we see that

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_s,l_s}) = \pm(\xi_{i_1,j_1} \cdots \xi_{i_{t-1},j_{t-1}})(\xi_{i_t,j_t} \cdots \xi_{k_s,l_s})$$

are the only ways to split the monomial so the left hand term occurs in $T_{i,g;x}(u)$ and the right hand term appears in $T_{g,j;y}(u)$ for some $x < g \leq y$. It just remains to check that the two have opposite signs.

Suppose instead that $\text{col}(j_r) < \text{col}(k_1)$ if $r > 0$ and that $x < \text{row}(l_t) \leq y$ for some $1 \leq t < s$. Choose the minimal such $t$ and let $h := \text{row}(l_t)$. Then the monomial $\pm \xi_{i_1,j_1} \cdots \xi_{i_r,j_r} \xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{i_1,h;x}(u)$ and the monomial $\pm \xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{h,j;y}(u)$. Moreover using the facts that $\text{col}(j_r) < \text{col}(k_1)$ if $r > 0$, $\text{col}(l_t) \geq \text{col}(k_{t+1})$, and the maximality of the choice of $t$, we have that

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}) = \pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r} \xi_{k_1,l_1} \cdots \xi_{k_s,l_s})$$

are the only ways to split the monomial so the first multiple occurs in $T_{i,g;x}(u)$ and the second multiple appears in $T_{g,j;y}(u)$ for some $x < g \leq y$. The two have opposite signs.

(ii) Similar.

(iii) Using (ii), we can rewrite (iii) as

$$T_{i,j;x}(u) - T_{i,j;y}(u) = \sum_{k=x+1}^{y} T_{i,k;x}(u)T_{k,j;y}(u). \tag{9.8}$$

The terms on the right hand side of (9.8) look like

$$\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}),$$

for various $r, s \geq 1$, where $\pm \xi_{i_1,j_1} \cdots \xi_{i_r,j_r}$ appears in $T_{i,k;x}(u)$ and $\pm \xi_{k_1,l_1} \cdots \xi_{k_s,l_s}$ appears in $T_{k,j;y}(u)$ for some $x < k \leq y$. Let $X$ be the sum of all such monomials for which $\text{col}(j_r) < \text{col}(k_1)$ and $\text{row}(l_t) \notin \{x + 1, \ldots, y\}$ for all $1 \leq t < s$. Let $Y$ be the sum of all such monomials for which $\text{col}(j_r) \geq \text{col}(k_1)$ and $\text{row}(l_t) \notin \{x + 1, \ldots, y\}$ for all $1 \leq t < r$. Let $Z$ be the sum of all the remaining monomials, so the right hand side of (9.8) is equal to $X + Y + Z$. We will show that $X + Y = T_{i,j;x}(u) - T_{i,j;y}(u)$ and that $Z = 0$.

So first consider $X + Y$. By definition, $T_{i,j;x}(u)$ is a sum of monomials of the form $\pm \xi_{p_1,q_1} \cdots \xi_{p_u,q_u}$. Let $A$ denote the sum of all these monomials with the property that $x < \text{row}(q_t) \leq y$ for some $1 \leq t < u$. Let $B$ be the sum of all the remaining monomials, so $T_{i,j;x}(u) = A + B$. Similarly, $T_{i,j;y}(u)$ is a sum of monomials $\pm \xi_{p_1,q_1} \cdots \xi_{p_u,q_u}$. Let $C$ denote the sum of all the ones with the property that $x < \text{row}(q_t) \leq y$ for some $1 \leq t < u$. Let $D$ denote the sum of all the rest, so $T_{i,j;y}(u) = C + D$. Now one checks that $X = A, Y = -C$ and $B = D$. Hence $X + Y = (A + B) - (C + D) = T_{i,j;x}(u) - T_{i,j;y}(u)$ as claimed.

It remains to show that $Z = 0$. Recall that $Z$ is the sum of all monomials of the form such that either $\text{col}(j_r) < \text{col}(k_1)$ and $x < \text{row}(l_t) \leq y$ for some $1 \leq t < s,$
or \( \text{col}(j_t) \geq \text{col}(k_1) \) and \( x < \text{row}(j_t) \leq y \) for some \( 1 \leq t < r \). In the former case, choose the minimal index \( t \geq 1 \) for which \( x < \text{row}(l_t) \leq y \). Then

\[
\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}), \pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r},\xi_{k_1,l_1} \cdots \xi_{k_t,l_t})(\xi_{k_{t+1},l_{t+1}} \cdots \xi_{k_s,l_s})
\]

are the only two ways to split the monomial \((9.10)\) so that the left hand term appears in \( T_{i,g;x}(u) \) and the right hand term appears in \( T_{g,j;y}(u) \) for some \( x < g \leq y \). Moreover, they appear in the expansion of \( Z \) with opposite signs. The latter case is similar, but one uses the maximal index \( t < r \) for which \( x < \text{row}(j_t) \leq y \).

(iv) The left hand side of the formula in (iv) is a sum of monomials of the form

\[
\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s})
\]

for various \( r, s \geq 0 \), where \( \pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r}) \) appears in \( T_{i,k;x}(u) \) and \( \pm(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}) \) appears in \( T_{k,j;y}(u) \) for some \( x < k \leq y \). Note that \( r = 0 \) is allowed only if \( i = k \), and \( s = 0 \) is allowed only if \( k = j \). So if \( i = j \) we get a contribution \(-1\) from the \( r = s = 0 \) term, while if \( i \neq j \) then there is no \( r = s = 0 \) term. Now the formula in (iv) will follow if we can show that whenever \((r, s) \neq (0, 0)\), the monomial \((9.10)\) appears exactly twice on the left hand side with opposite signs. We consider two cases.

First, suppose that \( s > 0 \) and that \( \text{col}(j_r) < \text{col}(k_1) \) if \( r > 0 \). Let \( t \geq 1 \) be the minimal index such that \( x < \text{row}(l_t) \leq y \); such a \( t \) exists as \( \text{row}(l_t) = j \) and \( x < j \leq y \). Let \( h := \text{row}(l_t) \). Then \( \pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r},\xi_{k_1,l_1} \cdots \xi_{k_t,l_t}) \) appears in \( T_{i,h;x}(u) \), and \( \pm(\xi_{k_{t+1},l_{t+1}} \cdots \xi_{k_s,l_s}) \) appears in \( T_{h,j;y}(u) \). Moreover, using the facts that \( \text{col}(l_t) \geq \text{col}(k_{t+1}) \) if \( t < s \), \( \text{col}(j_r) < \text{col}(k_1) \) if \( r > 0 \), and the minimality of the choice of \( t \), we see that

\[
\pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r})(\xi_{k_1,l_1} \cdots \xi_{k_s,l_s}), \pm(\xi_{i_1,j_1} \cdots \xi_{i_r,j_r},\xi_{k_1,l_1} \cdots \xi_{k_t,l_t})(\xi_{k_{t+1},l_{t+1}} \cdots \xi_{k_s,l_s})
\]

are the only ways to split the monomial \((9.10)\) so that the left term occurs in \( T_{i,g;x}(u) \) and the right term occurs in \( T_{g,j;y}(u) \) for some \( x < g \leq y \). The two have opposite signs.

For the second case, suppose either that \( s = 0 \) or that \( r, s > 0 \) and \( \text{col}(j_r) \geq \text{col}(k_1) \). Let \( t \leq r \) be the maximal index such that \( x < \text{row}(i_t) \leq y \) and argue in a similar fashion. \(\square\)

To explain the significance of this lemma, let \( T(u) := (T_{i,j;0}(u))_{1 \leq i,j \leq n} \), an \( n \times n \) matrix with entries in \( U(p)[[u^{-1}]] \). Also let \( \nu = (\nu_1, \ldots, \nu_m) \) be a fixed shape. Consider the Gauss factorization \( T(u) = F(u)D(u)E(u) \) where \( D(u) \) is a block diagonal matrix, \( E(u) \) is a block upper unitriangular matrix, and \( F(u) \) is a block lower unitriangular matrix, all block matrices being of shape \( \nu \). The diagonal blocks of \( D(u) \) define matrices \( D_1(u), \ldots, D_n(u) \), the upper diagonal blocks of \( E(u) \) define matrices \( E_1(u), \ldots, E_{m-1}(u) \), and the lower diagonal matrices of \( F(u) \) define matrices \( F_1(u), \ldots, F_{m-1}(u) \). Also let \( \bar{D}_a(u) := -D_a(u)^{-1} \). Thus \( D_a(u) = (D_{a,i;j}(u))_{1 \leq i,j \leq \nu_a} \) and \( \bar{D}_a(u) = (\bar{D}_{a,i;j}(u))_{1 \leq i,j \leq \nu_a} \) are \( \nu_a \times \nu_a \)-matrices, \( E_a(u) = (E_{a,i;j}(u))_{1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1}} \) is a \( \nu_a \times \nu_{a+1} \)-matrix, and \( F_a(u) = (F_{a,i;j}(u))_{1 \leq i \leq \nu_{a+1}, 1 \leq j \leq \nu_a} \) is a \( \nu_{a+1} \times \nu_a \)-matrix. Write

\[
D_{a,i;j}(u) = \sum_{r \geq 0} D_{a,i;j}^{(r)} u^{-r}, \quad \bar{D}_{a,i;j}(u) = \sum_{r \geq 0} \bar{D}_{a,i;j}^{(r)} u^{-r},
\]

\[
E_{a,i;j}(u) = \sum_{r > 0} E_{a,i;j}^{(r)} u^{-r}, \quad F_{a,i;j}(u) = \sum_{r > 0} F_{a,i;j}^{(r)} u^{-r},
\]
thus defining elements $D_{a;i,j}^{(r)}$, $E_{a;i,j}^{(r)}$ and $F_{a;i,j}^{(r)}$ of $U(p)$, all dependent of course on the fixed choice of $\nu$. All this parallels the definition of the elements of $Y_n$ with the same names in the paragraph following Lemma 9.1.

**Theorem 9.3.** With $\nu = (\nu_1, \ldots, \nu_m)$ fixed as above and all admissible $a, i, j$, we have that

$$
D_{a;i,j}(u) = T_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a-1}}(u),
$$

$$
\overline{D}_{a;i,j}(u) = T_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a}}(u),
$$

$$
E_{a;i,j}(u) = T_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a} + j; \nu_1 + \cdots + \nu_{a}}(u),
$$

$$
F_{a;i,j}(u) = T_{\nu_1 + \cdots + \nu_{a} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a}}(u).
$$

**Proof.** Note it suffices to prove the formulae for $D$, $E$ and $F$, since the one for $\overline{D}$ follows from the one for $D$ by Lemma 9.2(iv) taking $x = \nu_1 + \cdots + \nu_{a-1}$ and $y = \nu_1 + \cdots + \nu_{a}$. Now we proceed by induction on $m$, the base case $m = 1$ being trivial. For the induction step, suppose the theorem has been proved for the shape $\nu = (\nu_1, \ldots, \nu_m)$. So, in terms of matrices, we have that

$$
\nu D_{a}(u) = \left( T_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a-1}}(u) \right)_{1 \leq i, j \leq \nu_a},
$$

$$
\nu E_{a}(u) = \left( T_{\nu_1 + \cdots + \nu_{a-1} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a}}(u) \right)_{1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1}},
$$

$$
\nu F_{a}(u) = \left( T_{\nu_1 + \cdots + \nu_{a} + i, \nu_1 + \cdots + \nu_{a-1} + j; \nu_1 + \cdots + \nu_{a}}(u) \right)_{1 \leq i \leq \nu_{a+1}, 1 \leq j \leq \nu_a},
$$

where we have added a superscript $\nu$ for clarity. Write $\nu_b = \alpha + \beta$ for some $1 \leq b \leq m$ and $\alpha, \beta \geq 1$, and let $\mu = (\nu_1, \ldots, \nu_{b-1}, \alpha, \beta, \nu_{b+1}, \ldots, \nu_m)$. Define matrices $A, B, C$ and $D$ by

$$
A = \left( T_{\nu_1 + \cdots + \nu_{b-1} + i, \nu_1 + \cdots + \nu_{b-1} + j; \nu_1 + \cdots + \nu_{b-1}}(u) \right)_{1 \leq i, j \leq \alpha},
$$

$$
B = \left( T_{\nu_1 + \cdots + \nu_{b-1} + i, \nu_1 + \cdots + \nu_{b-1} + \alpha + j; \nu_1 + \cdots + \nu_{b-1} + \alpha}(u) \right)_{1 \leq i \leq \alpha, 1 \leq j \leq \beta},
$$

$$
C = \left( T_{\nu_1 + \cdots + \nu_{b-1} + \alpha + i, \nu_1 + \cdots + \nu_{b-1} + j; \nu_1 + \cdots + \nu_{b-1} + \alpha}(u) \right)_{1 \leq i \leq \beta, 1 \leq j \leq \alpha},
$$

$$
D = \left( T_{\nu_1 + \cdots + \nu_{b-1} + \alpha + i, \nu_1 + \cdots + \nu_{b-1} + \alpha + j; \nu_1 + \cdots + \nu_{b-1} + \alpha}(u) \right)_{1 \leq i, j \leq \beta}.
$$

Then Lemma 9.2(i)–(iii) with $x = \nu_1 + \cdots + \nu_{b-1}$ and $y = \nu_1 + \cdots + \nu_{b-1} + \alpha$ tell us that

$$
\nu D_{b}(u) = \left( \begin{array}{cc} A & AB \\ CA & D + CAB \end{array} \right) = \left( \begin{array}{cc} I_{\alpha} & 0 \\ C & I_{\beta} \end{array} \right) \left( \begin{array}{cc} A & 0 \\ 0 & D \end{array} \right) \left( \begin{array}{cc} I_{\alpha} & B \\ 0 & I_{\beta} \end{array} \right).
$$

Lemma 9.1 explains how to read off the matrices $\nu D_{a}(u)$, $\nu E_{a}(u)$ and $\nu F_{a}(u)$ from this factorization to get that

$$
\nu D_{a}(u) = \left( T_{\mu_1 + \cdots + \mu_{a-1} + i, \mu_1 + \cdots + \mu_{a-1} + j; \mu_1 + \cdots + \mu_{a-1}}(u) \right)_{1 \leq i, j \leq \mu_a},
$$

$$
\nu E_{a}(u) = \left( T_{\mu_1 + \cdots + \mu_{a-1} + i, \mu_1 + \cdots + \mu_{a} + j; \mu_1 + \cdots + \mu_{a}}(u) \right)_{1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{a+1}},
$$

$$
\nu F_{a}(u) = \left( T_{\mu_1 + \cdots + \mu_{a} + i, \mu_1 + \cdots + \mu_{a-1} + j; \mu_1 + \cdots + \mu_{a}}(u) \right)_{1 \leq i \leq \mu_{a+1}, 1 \leq j \leq \mu_a}.
$$

This completes the induction step. \qed

In the extreme case that $\nu = (1^n)$, we write simply $D_{i}^{(r)}$, $\overline{D}_{i}^{(r)}$, $E_{i}^{(r)}$ and $F_{i}^{(r)}$ for the elements $D_{i;1,1}^{(r)}$, $\overline{D}_{i;1,1}^{(r)}$, $E_{i;1,1}^{(r)}$ and $F_{i;1,1}^{(r)}$ of $U(p)$, respectively.
Corollary 9.4. $D_i^{(r)} = T_i^{(r)}_{i,i-1}, \tilde{D}_i^{(r)} = T_i^{(r)}_{i,i}, E_i^{(r)} = T_i^{(r)}_{i,i+1}$ and $F_i^{(r)} = T_{i+1,i,i}$.

10. Main theorem

Let $\pi$ be a pyramid of level $l$ with column heights $(q_1, \ldots, q_l)$. Pick an integer $n \geq \max(q_1, \ldots, q_l)$ and read off from the pyramid $\pi$ a shift matrix $\sigma = (s_{i,j})_{1 \leq i,j \leq n}$ according to (7.6). Define the finite $W$-algebra $W(\pi) = U(p)^m$ viewed as a filtered algebra via the Kazhdan filtration as in §8. Define the shifted Yangian $Y_{n,l}(\sigma)$ of level $l$ viewed as a filtered algebra via the canonical filtration as in §§2 and §5. Suppose also that $\nu = (\nu_1, \ldots, \nu_m)$ is an admissible shape for $\sigma$, and recall the notation $s_{a,b}(\nu)$ and $p_a(\nu)$ from §2 and §3. We have the elements $D_{a,i,j}^{(r)}, \tilde{D}_{a,i,j}^{(r)}, E_{a,i,j}^{(r)}$ and $F_{a,i,j}^{(r)}$ of $U(p)$ defined as in §9 relative to this fixed shape; see Theorem 9.3 for the explicit formulae. We also have the parabolic generators $D_{a,i,j}^{(r)}, \tilde{D}_{a,i,j}^{(r)}, E_{a,i,j}^{(r)}$ and $F_{a,i,j}^{(r)}$ of $Y_{n,l}(\sigma)$ as in §8. The main result of the article is as follows.

Theorem 10.1. There is a unique isomorphism $Y_{n,l}(\sigma) \sim W(\pi)$ of filtered algebras such that for any admissible shape $\nu = (\nu_1, \ldots, \nu_m)$ the generators

\[
\{D_{a,i,j}^{(r)}\}_{1 \leq a \leq m, 1 \leq i,j \leq \nu_a, r > 0},
\{E_{a,i,j}^{(r)}\}_{1 \leq a < m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1}, r > s_{a,b}(\nu)},
\{F_{a,i,j}^{(r)}\}_{1 \leq a < m, 1 \leq i \leq \nu_{a+1}, 1 \leq j \leq \nu_a, r > s_{a,b}(\nu)}
\]

of $Y_{n,l}(\sigma)$ map to the elements of $U(p)$ with the same names. In particular, these elements of $U(p)$ are $m$-invariants and they generate $W(\pi)$.

The proof will take up most of the rest of the section. First however let us record a couple of corollaries of the theorem.

Corollary 10.2. The map $\theta : gr W(\pi) \to S(c_\varphi(e))$ from (8.4) is an isomorphism.

Proof. Since we already know by Corollary 8.3 that the map $\theta$ is an injective, graded homomorphism, it suffices given Theorem 10.1 to show that $gr Y_{n,l}(\sigma)$ and $S(c_\varphi(e))$ have the same dimension in each degree. This follows from Theorem 8.2 and Lemma 7.3 (the element $c_{i,j}^{(r)}$ there is of degree $r$ with respect to the Kazhdan grading). \hfill $\square$

For the next corollary, let $\tilde{\pi}$ be another pyramid with the same row lengths as $\pi$, i.e. the nilpotent matrix $\hat{e}$ defined from $\tilde{\pi}$ is conjugate to the nilpotent matrix $e$ defined from $\pi$. Let $\tilde{\sigma} = (\tilde{s}_{i,j})_{1 \leq i,j \leq n}$ be a shift matrix corresponding to the pyramid $\tilde{\pi}$. By Theorem 10.1, the formulae in §9 define generators $D_{a,i,j}^{(r)}, \tilde{D}_{a,i,j}^{(r)}, E_{a,i,j}^{(r)}$ and $\tilde{F}_{a,i,j}^{(r)}$ of $W(\tilde{\pi})$ for each admissible shape $\nu$.

Corollary 10.3. There is an algebra isomorphism $\iota : W(\pi) \to W(\tilde{\pi})$ defined on parabolic generators with respect to an admissible shape $\nu$ by (6.24).

Proof. This follows from Theorem 10.1 and (6.3). \hfill $\square$

So now we must prove Theorem 10.1. The first reduction is to observe that it suffices to prove it in the special case that $\nu$ is the minimal admissible shape for $\sigma$. It then follows for all other admissible shapes by Lemma 8.1 and induction on the length of the shape. So we assume from now on that $\nu = (\nu_1, \ldots, \nu_m)$ is the minimal admissible
shape for $\sigma$, and let $t := \nu_m = \min(q_1, q_l)$. We proceed to prove Theorem $10.1$ by induction on the level $l$. Consider first the base case $l = 1$, i.e. $\pi$ consists of a single column of height $t$. Since the nilpotent element $e$ from (7.3) is zero in this case, we have by definition that $W(\pi) = U(\mathfrak{gl}_t)$. Moreover, according to Theorem 9.3 we have that $D_m^{(1)} = \delta_{1,j} = e_{i,j} = \delta_{1,j}, (n-t)$ for $1 \leq i, j \leq t$, and all other elements $F^{(r)}_{a^i,j}$ and $E^{(r)}_{a^i,j}$ of $W(\pi)$ are equal to zero. On the other hand, it follows from the relations and Corollary 6.3 that

$$\pi \, \Rightarrow \, U(\mathfrak{gl}_t) \quad \text{such that} \quad D_m^{(1)} \mapsto e_{i,j}, \quad \text{with all the other parabolic generators} \quad F^{(r)}_{a^i,j}, E^{(r)}_{a^i,j} \quad \text{of} \quad W(\pi) \quad \text{mapping to zero.}$$

Assume from now on that $t > 1$ and that the theorem has been proved for all smaller levels. The verification of the induction step splits into two cases corresponding to the two possible baby combinolutions $\Delta_R$ and $\Delta_L$ that were defined in (6.7)–(6.8):

**Case $\Delta_R$:** either $t = n$ or $s_{n-t, n-t+1} \neq 0$;

**Case $\Delta_L$:** either $t = n$ or $s_{n-t+1, n-t} \neq 0$.

The argument in the two cases is quite similar. We will explain it in detail in case $\Delta_R$, then briefly indicate the changes in case $\Delta_L$.

So assume that either $t = n$ or $s_{n-t, n-t+1} = s_{n-1, n} \neq 0$; in particular, $q_1 \geq q_l$.

For notational convenience, assume that the numbering of the bricks of the pyramid $\pi$ is the standard numbering down columns from left to right. Let $\hat{\pi}$ be the pyramid obtained from $\pi$ by removing the rightmost column, i.e. the bricks numbered $(N - t + 1), (N - t + 2), \ldots, N$, from the pyramid $\pi$. Let $\sigma = (s_{i,j})_{1 \leq i, j \leq n}$ be the shift matrix corresponding to the pyramid $\hat{\pi}$ defined by (1.5). Define $\hat{\mathfrak{g}}, \hat{\mathfrak{m}}$ and $\hat{\mathfrak{e}}$ in $\hat{\mathfrak{g}} = \mathfrak{gl}_{N-t}$ according to (7.3)–(7.4) and let $\hat{\chi} : \hat{\mathfrak{m}} \to \mathbb{C}$ be the character $x \mapsto (x, \hat{\mathfrak{e}})$. Let $\hat{D}^{(r)}_{a^i,j}, \hat{F}^{(r)}_{a^i,j}, \hat{E}^{(r)}_{a^i,j}$ and $\hat{F}^{(r)}_{a^i,j}$ denote the elements of $U(\hat{\mathfrak{g}})$ as defined in (9.3) relative to the shape $\nu$. By the induction hypothesis, Theorem 10.1 holds for $\hat{\pi}$, so we know already that the following elements of $U(\hat{\mathfrak{g}})$ are invariant under the twisted action of $\hat{\mathfrak{m}}$, i.e. they belong to finite $W$-algebra $W(\hat{\pi}) = U(\hat{\mathfrak{g}})$:

(i) $\hat{D}^{(r)}_{a^i,j}, \hat{D}^{(r)}_{a^i,j}$ for $1 \leq a \leq m, 1 \leq i, j < \nu_a$ and $r > 0$;

(ii) $\hat{E}^{(r)}_{a^i,j}$ for $1 \leq a < m, 1 \leq i < \nu_a, 1 \leq j < \nu_{a+1}$ and $r > s_{a,a+1}(\nu) - \delta_{a,m-1}$;

(iii) $\hat{F}^{(r)}_{a^i,j}$ for $1 \leq a < m, 1 \leq i < \nu_{a+1}, 1 \leq j < \nu_a$ and $r > s_{a+1,a}(\nu)$.

Recalling (9.2), we must work now with the non-standard embedding of $U(\mathfrak{g})$ into $U(\mathfrak{g})$ under which the generators $\hat{\mathfrak{e}}_{i,j}$ of $U(\hat{\mathfrak{g}})$ defined from the pyramid $\pi$, for $1 \leq i, j \leq N-t$. This also embeds $U(\mathfrak{p})$ into $U(\mathfrak{g})$ and $\hat{\mathfrak{m}}$ into $\hat{\mathfrak{m}}$. Moreover, recalling (7.2), the character $\hat{\chi}$ of $\hat{\mathfrak{m}}$ is the restriction of the character $\chi$ of $\mathfrak{m}$, hence the twisted action of $\hat{\mathfrak{m}}$ on $U(\hat{\mathfrak{g}})$ is the restriction of the twisted action of $\mathfrak{m}$ on $U(\mathfrak{p})$. The following crucial lemma gives us an inductive description of the elements $\hat{D}^{(r)}_{a^i,j}, \hat{E}^{(r)}_{a^i,j}$ and $\hat{F}^{(r)}_{a^i,j}$ of $U(\hat{\mathfrak{g}})$; this should be compared with Theorem 4.1.
Lemma 10.4. The following equations hold for $r > 0$, all admissible $a, i, j$ and any fixed $1 \leq h \leq t$:

\[
D_{a;i,j}^{(r)} = \tilde{D}_{a;i,j}^{(r)} + \delta_{a,m} \left( \sum_{k=1}^{t} \tilde{D}_{a;i,k}^{(r-1)} \tilde{e}_{N-t+k,N-t+j} + \left[ \tilde{D}_{a;i,h}^{(r-1)} \tilde{e}_{N-2t+h,N-t+j} \right] \right),
\]

(10.1)

\[
E_{a;i,j}^{(r)} = \tilde{E}_{a;i,j}^{(r)} + \delta_{a,m-1} \left( \sum_{k=1}^{t} \tilde{E}_{a;i,k}^{(r-1)} \tilde{e}_{N-t+k,N-t+j} + \left[ \tilde{E}_{a;i,h}^{(r-1)} \tilde{e}_{N-2t+h,N-t+j} \right] \right),
\]

(10.2)

\[
F_{a;i,j}^{(r)} = \tilde{F}_{a;i,j}^{(r)},
\]

(10.3)

where for (10.2) we are assuming that $r > 1$ if $a = m - 1$.

Proof. This follows using Theorem 9.3 and the explicit form of the elements $T_{i;j;x}^{(r)}$ from

In the next few lemmas we will use these inductive descriptions to show that the elements $D_{a;i,j}^{(r)}$, $E_{a;i,j}^{(r)}$, and $F_{a;i,j}^{(r)}$ of $U(\mathfrak{p})$ are $m$-invariants for the appropriate $r$.

Lemma 10.5. The following elements of $U(\mathfrak{p})$ are invariant under the twisted action of $m$:

(i) $D_{a;i,j}^{(r)}$ and $\tilde{D}_{a;i,j}^{(r)}$ for $1 \leq a \leq m - 1$, $1 \leq i, j \leq \nu_a$ and $r > 0$;

(ii) $E_{a;i,j}^{(r)}$ for $1 \leq a < m - 1$, $1 \leq i \leq \nu_a$, $1 \leq j \leq \nu_{a+1}$ and $r > s_{a,a+1}(\nu)$;

(iii) $F_{a;i,j}^{(r)}$ for $a = 1 \leq a < m$, $1 \leq i \leq \nu_{a+1}$, $1 \leq j \leq \nu_a$ and $r > s_{a+1,a}(\nu)$.

Proof. By Lemma 10.4 and the definitions of $\tilde{D}_{a;i,j}^{(r)}$ and $\tilde{D}_{a;i,j}^{(r)}$, all these elements of $U(\mathfrak{p})$ coincide with the corresponding elements of $\tilde{U}(\mathfrak{p})$. Hence by the induction hypothesis we already know they are invariant under the twisted action of $\tilde{m}$. It remains to show that the elements are invariant under the twisted action of all $\tilde{e}_{f,g}$ with $1 \leq g \leq N - t < f \leq N$. By Theorem 9.3 and the explicit form of (9.5), all the elements we are considering are linear combinations of monomials of the form $\tilde{e}_{i_1,j_1} \cdots \tilde{e}_{i_r,j_r} \in U(\mathfrak{p})$ with $1 \leq i_s \leq N - t$ and $1 \leq j_s \leq N - 2t$ for all $s = 1, \ldots, r$. Using just the fact that $\chi(\tilde{e}_{f,g}) = 0$ for all $1 \leq g \leq N - 2t$ and $N - t < f \leq N$, it is easy to see that all such monomials are invariant under the twisted action of all $\tilde{e}_{f,g}$ with $1 \leq g \leq N - t < f \leq N$.

Lemma 10.6. The following elements of $U(\mathfrak{p})$ are invariant under the twisted action of $\tilde{m}$:

(i) $D_{m;i,j}^{(r)}$ for $1 \leq i, j \leq \nu_m$ and $r > 0$;

(ii) (assuming $t < n$) $E_{m-1;i,j}^{(r)}$ for $1 \leq i \leq \nu_{m-1}$, $1 \leq j \leq \nu_m$ and $r > s_{m-1,m}(\nu)$.

Proof. (i) Take $x \in \tilde{m}$. According to Lemma 10.4 we have that

\[
D_{m;i,j}^{(r)} = \tilde{D}_{m;i,j}^{(r)} + \sum_{k=1}^{t} \tilde{D}_{m;i,k}^{(r-1)} \tilde{e}_{N-t+k,N-t+j} + \left[ \tilde{D}_{m;i,h}^{(r-1)} \tilde{e}_{N-2t+h,N-t+j} \right].
\]

Noting that $[x, \tilde{e}_{N-t+k,N-t+j}] = [x, \tilde{e}_{N-2t+h,N-t+j}] = 0$ and using the induction hypothesis, one deduces easily from this equation that $\text{pr}_\chi([x, D_{m;i,j}^{(r)}]) = 0$ as required.

(ii) Similar.
Lemma 10.7. The following elements of $U(p)$ are invariant under the twisted action of $\delta_{f,g}$ for all $1 \leq g \leq N - t < f \leq N$:

(i) $D_{m;i,j}^{(1)}$ for $1 \leq i, j \leq \nu_m$;

(ii) (assuming $t < n$ and $s_{m-1,m}(\nu) = 1$) $D_{m;i,j}^{(2)}$ for $1 \leq i, j \leq \nu_m$;

(iii) (assuming $t < n$ and $s_{m-1,m}(\nu) = 1$) $E_{m-1;i,j}^{(2)}$ for $1 \leq i \leq \nu_{m-1}$, $1 \leq j \leq \nu_m$.

Proof. Part (i) is easily checked directly using (10.3) and (10.4) and the explicit formula for $D_{m;i,j}^{(1)}$ given by Theorem 10.3 and Example 10.1. The proofs of (ii) and (iii) are similar, though the calculations are not so easy.

Lemma 10.8. Suppose that $t < n$ and $s_{m-1,m}(\nu) = 1$. Then, the following equations hold in $U(p)$ for $r > 1$, all admissible $i,j$ and any fixed $1 \leq g \leq \nu_{m-1}$:

$$D_{m;i,j}^{(r+1)} = [F_{m-1;i,g}^{(2)} E_{m-1,g,j}^{(r)}] + \sum_{s=0}^{r} D_{m-1;i,g}^{(r+1-s)} D_{m;i,j}^{(s)},$$  \hspace{1cm} (10.4)

$$E_{m-1;i,j}^{(r+1)} = [D_{m-1;i,g}^{(2)} E_{m-1,g,j}^{(r)}] - \sum_{f=1}^{\nu_{m-1}} D_{m-1;i,f}^{(1)} E_{m-1;f,j}^{(r)},$$  \hspace{1cm} (10.5)

Proof. We prove (10.5), the first equation being a similar trick. By the induction hypothesis and the relation (3.5), we know for all $r > 0$ that

$$[\dot{D}_{m-1;i,g}^{(2)} \dot{E}_{m-1,g,j}^{(r)}] = \dot{E}_{m-1;i,j}^{(r+1)} + \sum_{f=1}^{\nu_{m-1}} \dot{D}_{m-1;i,f}^{(1)} \dot{E}_{m-1;f,j}^{(r)}.$$  \hspace{1cm}

By Lemma 10.4 we have for $r > 1$ that

$$E_{m-1,g,j}^{(r)} = \dot{E}_{m-1,g,j}^{(r)} + \sum_{k=1}^{t} E_{m-1,g,k}^{(r-1)} \delta_{N-t+k,N-t+j} + [E_{m-1,g,h}^{(r-1)} \delta_{N-2t+h,N-t+j}].$$

Obviously, $[\dot{D}_{m-1;i,g}^{(2)} \dot{\delta}_{N-t+k,N-t+j}] = 0$. Moreover, by Theorem 9.3 and the form of (9.5), no monomial in the expansion of $\dot{D}_{m-1;i,g}^{(2)}$ involves any matrix unit of the form $\delta_{N-t+k,N-t+j}$. Hence $[\dot{D}_{m-1;i,g}^{(2)} \dot{\delta}_{N-2t+h,N-t+j}] = 0$ too. Now we can commute with $\dot{D}_{m-1;i,g}^{(2)}$ to deduce that

$$[D_{m-1;i,g}^{(2)} E_{m-1;g,j}^{(r)}] = \dot{E}_{m-1;i,j}^{(r+1)} + \sum_{f=1}^{\nu_{m-1}} \dot{D}_{m-1;i,f}^{(1)} \dot{E}_{m-1;f,j}^{(r)}$$

$$+ \sum_{k=1}^{t} \left\{ \dot{E}_{m-1;i,k}^{(r)} + \sum_{f=1}^{\nu_{m-1}} \dot{D}_{m-1;i,f}^{(1)} \dot{E}_{m-1;f,k}^{(r-1)} \right\} \delta_{N-t+k,N-t+j}$$

$$+ \left[ \dot{E}_{m-1;i,h}^{(r)} + \sum_{f=1}^{\nu_{m-1}} \dot{D}_{m-1;i,f}^{(1)} \dot{E}_{m-1;f,h}^{(r-1)} \right] \delta_{N-2t+h,N-t+j}.$$  \hspace{1cm}

Finally rewrite the right hand side using Lemma 10.4 again to see that it equals $E_{m-1;i,j}^{(r+1)} + \sum_{f=1}^{\nu_{m-1}} D_{m-1;i,f}^{(1)} E_{m-1;f,j}^{(r)}$. \qed
Lemma 10.9. Suppose that $t = n$ and $l > 1$ or that $t < n$ and $s_{m-1,m}(\nu) > 1$. Then the following elements of $U(\mathfrak{p})$ are invariant under the twisted action of $\tilde{e}_{N-t+f,N-2t+g}$ for all $1 \leq f, g \leq t$.

(i) $D_{m,i,j}^{(r)}$ for $1 \leq i, j \leq \nu_m$ and $r > 1$;

(ii) (assuming $t < n$) $E_{m-1,i,j}^{(r)}$ for $1 \leq i \leq \nu_{m-1}$, $1 \leq j \leq \nu_m$ and $r > s_{m-1,m}(\nu)$.

Proof. (i) Let $\hat{\pi}$ denote the pyramid obtained by removing the rightmost column from the pyramid $\pi$, i.e., the bricks numbered $(N - 2t + 1), (N - 2t + 2), \ldots, (N - t)$. Define $\tilde{p}, \tilde{m}$ and $\tilde{e}$ in $\tilde{\mathfrak{g}} = gl_{N-2t}$ according to (7.3)–(7.4), and embed $U(\tilde{\mathfrak{g}})$ into $U(\mathfrak{g})$ in exactly the same (non-standard) way as we embedded $U(\tilde{\mathfrak{g}})$ into $U(\mathfrak{g})$. We will make use of the elements $\tilde{D}_{a,i,j}^{(r)}$ of $W(\tilde{\pi})$. By Lemma 10.4 applied to $\tilde{\pi}$, the following equation holds for $r > 0$, $1 \leq i, j \leq \nu_m$ and any fixed $1 \leq h \leq t$:

$$\tilde{D}_{m;i,j}^{(r)} = \tilde{D}_{m;i,j}^{(r)} + \sum_{c=1}^{t} \tilde{D}_{m;i,c}^{(r-1)} \tilde{e}_{N-2t+c,N-2t+j} + [\tilde{D}_{m;i,h}^{(r-1)}, \tilde{e}_{N-3t+h,N-2t+j}].$$

Substituting this into (10.1) and simplifying a little using (9.3) we deduce for $r > 1$ that $D_{m;i,j}^{(r)} = A + B + C + D + E + F + G + H$ where

$$A = \tilde{D}_{m;i,j}^{(r)}, \quad E = \sum_{k,c=1}^{t} \tilde{D}_{m;i,c}^{(r-2)} \tilde{e}_{N-2t+c,N-2t+k,N-t+j},$$

$$B = \sum_{c=1}^{t} \tilde{D}_{m;i,c}^{(r-1)} \tilde{e}_{N-2t+c,N-2t+j}, \quad F = \sum_{k=1}^{t} \tilde{D}_{m;i,h}^{(r-2)} \tilde{e}_{N-3t+h,N-2t+k} \tilde{e}_{N-t+k,N-t+j},$$

$$C = [\tilde{D}_{m;i,h}^{(r-1)}, \tilde{e}_{N-3t+h,N-2t+j}], \quad G = \sum_{c=1}^{t} \tilde{D}_{m;i,c}^{(r-2)} \tilde{e}_{N-2t+c,N-t+j},$$

$$D = \sum_{k=1}^{t} \tilde{D}_{m;i,k}^{(r-1)} \tilde{e}_{N-t+k,N-t+j}, \quad H = [\tilde{D}_{m;i,h}^{(r-2)}, \tilde{e}_{N-3t+h,N-t+j}].$$

Now commute each of these elements in turn with $x := \tilde{e}_{N-t+f,N-2t+g}$ then apply $\text{pr}_x$, using (10.1), (10.3), (10.4) and the observation that $x$ commutes with all elements of $U(\tilde{\mathfrak{p}})$, to deduce that

$$\text{pr}_x([x, A]) = 0, \quad \text{pr}_x([x, C]) = 0,$$

$$\text{pr}_x([x, B]) = -\delta_{f,j} \tilde{D}_{m;i,g}^{(r-1)} \tilde{e}_{N-t+f,N-t+j}, \quad \text{pr}_x([x, D]) = \delta_{f,j} \tilde{D}_{m;i,g}^{(r-1)},$$

$$\text{pr}_x([x, E]) = t\delta_{f,j} \tilde{D}_{m;i,g}^{(r-2)} \tilde{e}_{N-t+f,N-t+j} - \delta_{f,j} \tilde{D}_{m;i,g}^{(r-2)} \tilde{e}_{N-2t+c,N-2t+g},$$

$$\text{pr}_x([x, F]) = \delta_{f,j} [\tilde{D}_{m;i,h}^{(r-2)}, \tilde{e}_{N-3t+h,N-2t+g}],$$

$$\text{pr}_x([x, G]) = \tilde{D}_{m;i,g}^{(r-2)} \tilde{e}_{N-t+f,N-t+j} - t\delta_{f,j} \tilde{D}_{m;i,g}^{(r-2)} - \delta_{f,j} \sum_{c=1}^{t} \tilde{D}_{m;i,c}^{(r-2)} \tilde{e}_{N-2t+c,N-2t+g},$$

$$\text{pr}_x([x, H]) = -\delta_{f,j} [\tilde{D}_{m;i,h}^{(r-2)}, \tilde{e}_{N-3t+h,N-2t+g}].$$

These sum to zero, hence $\text{pr}_x([x, D_{m;i,j}^{(r)}]) = 0$. 

(ii) Similar.

**Lemma 10.10.** The following elements of $U(\mathfrak{p})$ are invariant under the twisted action of $\mathfrak{m}$:

(i) $D_{a;i,j}^{(r)}$ for $1 \leq a \leq m$, $1 \leq i, j \leq \nu_a$ and $r > 0$;

(ii) $E_{a;i,j}^{(r)}$ for $1 \leq a < m$, $1 \leq i \leq \nu_a$, $1 \leq j \leq \nu_{a+1}$ and $r > s_{a,a+1}(\nu)$;

(iii) $F_{a;i,j}^{(r)}$ for $1 \leq a < m$, $1 \leq i \leq \nu_{a+1}$, $1 \leq j \leq \nu_a$ and $r > s_{a+1,a}(\nu)$.

**Proof.** This is just a matter of assembling the pieces. Lemma 10.5 covers all the elements except $D_{m;i,j}^{(r)}$ and (assuming $t < n$) $E_{m-1;i,j}^{(r)}$. Since $\mathfrak{m}$ is generated by $\tilde{m}$ and the elements $\tilde{e}_{f,g}$ for all $1 \leq f, g \leq N$ with col($f$) = $l$, col($g$) = $l - 1$, Lemma 10.9 reduces the problem to showing that the elements $D_{m;i,j}^{(r)}$ for $r > 0$ and (assuming $t < n$) $E_{m-1;i,j}^{(r)}$ for $r > s_{m-1,m}(\nu)$ are invariant under all such $\tilde{e}_{f,g}$. Suppose first that $t = n$. Then the required invariance is checked in Lemma 10.7(i) and Lemma 10.9(i). Now assume that $t < n$. If $s_{m-1,m}(\nu) = 1$, then the invariance of $D_{m;i,j}^{(1)}$, $D_{m;i,j}^{(2)}$ and $E_{m-1;i,j}^{(r)}$ is checked in Lemma 10.7. The invariance of all higher $D_{m;i,j}^{(r)}$ and $E_{m-1;i,j}^{(r)}$ then follows by Lemma 10.5, Lemma 10.8 and induction on $r$. Finally if $s_{m-1,m}(\nu) > 1$ then the invariance of $D_{m;i,j}^{(1)}$ is checked in Lemma 10.7(i), and the remaining elements are covered by Lemma 10.9. □

Now we complete the proof of the induction step in case $\Delta_R$. By the induction hypothesis, we can identify the shifted Yangian $Y_{n,t-1}(\tilde{\sigma})$ with $W(\tilde{\pi}) \subseteq U(\tilde{\mathfrak{p}})$, so that the generators $\tilde{D}_{a;i,j}^{(r)}$, $\tilde{E}_{a;i,j}^{(r)}$ and $\tilde{F}_{a;i,j}^{(r)}$ of $Y_{n,t-1}(\tilde{\sigma})$ coincide with the elements of $W(\tilde{\pi})$ with the same name. Theorem 5.2 then shows that there is an injective algebra homomorphism $\Delta_R : Y_{n,t}(\sigma) \to U(\mathfrak{p}) \otimes U(\mathfrak{gl}_t)$. Observe moreover comparing Theorem 6.2 with Lemma 7.5 (like in the proof of Corollary 10.2) that for each $d \geq 0$,

$$\dim \Delta_R(F_dY_{n,t}(\sigma)) = \dim F_dY_{n,t}(\sigma) = \dim F_dS(\mathfrak{e}(\mathfrak{g})(e)), \quad (10.6)$$

where $F_dS(\mathfrak{e}(\mathfrak{g})(e))$ denotes the sum of all the graded pieces of $S(\mathfrak{e}(\mathfrak{g})(e))$ of degree $\leq d$ in the Kazhdan grading. Define elements $E_{a,b;i,j}^{(r)}$ and $F_{a,b;i,j}^{(r)}$ of $F_tU(\mathfrak{p})$ recursively by the formulae 8.15 - 8.16, making arbitrary choices for the integers $k$ appearing there. Let $X_d$ denote the subspace of $U(\mathfrak{p})$ spanned by all monomials in

$$\{D_{a;i,j}^{(r)}\}_{1 \leq a \leq m, 1 \leq i, j \leq \nu_a, 0 < r \leq s_a(\nu)};$$

$$\{E_{a,b;i,j}^{(r)}\}_{1 \leq a < m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1}, s_{a,a+1}(\nu) + p_a(\nu) < r \leq s_{a,b}(\nu)};$$

$$\{F_{a,b;i,j}^{(r)}\}_{1 \leq a < m, 1 \leq i \leq \nu_b, 1 \leq j \leq \nu_{a,b}, s_{b,a}(\nu) + p_b(\nu) < r \leq s_{a,b}(\nu) + p_a(\nu)}$$

taken in some fixed order and of total degree $\leq d$. By Lemma 10.10, $X_d$ is actually a subspace of $F_dW(\pi)$. Define an algebra homomorphism $\varphi_R : U(\mathfrak{p}) \to U(\mathfrak{p}) \otimes U(\mathfrak{gl}_t)$ by

$$\varphi_R(\tilde{e}_{i,j}) = \begin{cases} \tilde{e}_{i,j} \otimes 1 & \text{if } \text{col}(i) \leq \text{col}(j) \leq l - 1, \\ 0 & \text{if } \text{col}(i) \leq l - 1, l = \text{col}(j), \\ 1 \otimes \tilde{e}_{i-N+t,j-N+t} & \text{if } l = \text{col}(i) = \text{col}(j), \end{cases} \quad (10.7)$$
where \( \tilde{e}_{i-N+t,j-N+t} \in U(\mathfrak{gl}_t) \) denotes \( e_{i-N+t,j-N+t} + \delta_{i,j}(n-t) \) like in Theorem 4.1.

By Lemma 10.4, we have that

\[
\varphi_R(D^{(r)}_{a,i,j}) = \hat{D}^{(r)}_{a,i,j} \otimes 1 + \delta_{a,m} \sum_{k=1}^t \hat{D}^{(r-1)}_{a,i,k} \otimes \tilde{e}_{k,j},
\]

\( (10.8) \)

\[
\varphi_R(E^{(r)}_{a,i,j}) = \hat{E}^{(r)}_{a,i,j} \otimes 1 + \delta_{a,m-1} \sum_{k=1}^t \hat{E}^{(r-1)}_{a,i,k} \otimes \tilde{e}_{k,j},
\]

\( (10.9) \)

\[
\varphi_R(F^{(r)}_{a,i,j}) = \hat{F}^{(r)}_{a,i,j} \otimes 1.
\]

\( (10.10) \)

Comparing this with Theorem 4.1(i) and recalling the PBW basis for \( F_d Y_{n,l}(\sigma) \) from Theorem 6.2 and Corollary 6.3, we see that \( \varphi_R(X_d) = \Delta_R(F_d Y_{n,l}(\sigma)) \). Combining this with (10.6) and Corollary 8.3, we deduce that

\[ \dim F_d S(\epsilon_d(e)) = \dim \varphi_R(X_d) \leq \dim X_d \leq \dim F_d W(\pi) \leq \dim F_d S(\epsilon_d(e)). \]

Hence equality holds everywhere, so we get that \( X_d = F_d W(\pi) \) for each \( d \geq 0 \), and the map \( \varphi_R : W(\pi) \rightarrow U(\hat{\mathfrak{g}}) \otimes U(\mathfrak{gl}_t) \) is injective with the same image as \( \Delta_R : Y_{n,l}(\sigma) \rightarrow U(\hat{\mathfrak{g}}) \otimes U(\mathfrak{gl}_t) \). In particular this shows that the elements listed in Theorem 10.1 generate \( W(\pi) \), and the map \( \varphi_R^{-1} \circ \Delta_R : Y_{n,l}(\sigma) \rightarrow W(\pi) \) is exactly the filtered algebra isomorphism described in the statement of Theorem 10.1. This completes the proof of the induction step in the case \( \Delta_R \).

Finally we must sketch the proof of the induction step in the case \( \Delta_L \). So assume that either \( t = n \) or \( s_{n-t+1,n-t} = s_{m,m-1}(\nu) \neq 0 \); in particular, \( q_1 \leq q_t \). This time it is notationally convenient to number of the bricks of the pyramid \( \pi \) down columns from right to left, not from left to right as before. For instance, the entries down the first (leftmost) column of the pyramid are \( (N-t+1), (N-t+2), \ldots, N \) in this new numbering. Let \( \hat{\sigma} \) be the pyramid obtained from \( \pi \) by removing this column from the pyramid \( \pi \). Let \( \hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n} \) be the shift matrix corresponding to the pyramid \( \hat{\pi} \) defined by (4.6). Define \( \hat{\mathfrak{g}}, \hat{m} \) and \( \hat{e} \) in \( \hat{\mathfrak{g}} = \mathfrak{gl}_{N-t} \) according to (7.8)–(7.9). This time, we can work simply with the natural embedding of \( U(\mathfrak{g}) \) into \( U(\hat{\mathfrak{g}}) \) induced by the usual embedding of \( \mathfrak{g} \) into \( \hat{\mathfrak{g}} \), since this already maps the elements \( \tilde{e}_{i,j} \) of \( U(\hat{\mathfrak{g}}) \) to the elements \( \tilde{e}_{i,j} \) of \( U(\mathfrak{g}) \) for \( 1 \leq i,j \leq N-t \). The algebra \( W(\hat{\pi}) = U(\hat{\mathfrak{g}}) \hat{m} \) is a subalgebra of \( U(\hat{\mathfrak{g}}) \subset U(\mathfrak{g}) \), \( \hat{m} \) is a subalgebra of \( \hat{m} \), and the twisted action of \( \hat{m} \) on \( U(\hat{\mathfrak{g}}) \) is the restriction of the twisted action of \( \hat{m} \) on \( U(\mathfrak{g}) \). Let \( \hat{D}^{(r)}_{a,i,j}, \hat{D}^{(r)}_{a,\hat{i},j}, \hat{E}^{(r)}_{a,i,j} \) and \( F^{(r)}_{a,i,j} \) denote the elements of \( U(\hat{\mathfrak{g}}) \) as defined in (4) relative to the shape \( \nu \). The all-important analogue of Lemma 10.4 is as follows.

**Lemma 10.11.** The following equations hold for \( r > 0 \), all admissible \( a, i, j \) and any fixed \( 1 \leq l \leq t \):

\[
D^{(r)}_{a,i,j} = \hat{D}^{(r)}_{a,i,j} + \delta_{a,m} \left( \sum_{k=1}^t \tilde{e}_{N-t+i,N-t+k} \hat{E}^{(r-1)}_{a,k,j} + \left[ \tilde{e}_{N-t+i,N-2t+h} \hat{D}^{(r-1)}_{a,h,j} \right] \right),
\]

\( (10.11) \)

\[
E^{(r)}_{a,i,j} = \hat{E}^{(r)}_{a,i,j},
\]

\( (10.12) \)

\[
F^{(r)}_{a,i,j} = \hat{F}^{(r)}_{a,i,j} + \delta_{a,m-1} \left( \sum_{k=1}^t \tilde{e}_{N-t+i,N-t+k} \hat{F}^{(r-1)}_{a,k,j} + \left[ \tilde{e}_{N-t+i,N-2t+h} \hat{F}^{(r-1)}_{a,h,j} \right] \right),
\]

\( (10.13) \)
where for (10.15) we are assuming that \( r > 1 \) if \( a = m - 1 \).

Combining this with the induction hypothesis and imitating the arguments in Lemmas 10.5, 10.10 one can now check:

**Lemma 10.12.** The following elements of \( U(p) \) are invariant under the twisted action of \( m \):

(i) \( D_{a;i,j}^{(r)} \) for \( 1 \leq a \leq m, 1 \leq i, j \leq \nu_a \) and \( r > 0 \);

(ii) \( E_{a;i,j}^{(r)} \) for \( 1 \leq a < m, 1 \leq i \leq \nu_a, 1 \leq j \leq \nu_{a+1} \) and \( r > s_{a,a+1}(\nu) \);

(iii) \( F_{a;i,j}^{(r)} \) for \( 1 \leq a < m, 1 \leq i \leq \nu_{a+1}, 1 \leq j \leq \nu_a \) and \( r > s_{a+1,a}(\nu) \).

Finally, define an algebra homomorphism \( \varphi_L : U(p) \to U(gl_t) \otimes U(\hat{p}) \) by

\[
\varphi_L(e_{i,j}) = \begin{cases} 
\tilde{e}_{i-N+t,j-N+t} \otimes 1 & \text{if } \text{col}(i) = \text{col}(j) = 1, \\
0 & \text{if } \text{col}(i) = 1, 2 \leq \text{col}(j), \\
1 \otimes \tilde{e}_{i,j} & \text{if } 2 \leq \text{col}(i) \leq \text{col}(j),
\end{cases}
\]

where \( \tilde{e}_{i-N+t,j-N+t} \in U(gl_t) \) denotes \( e_{i-N+t,j-N+t} + \delta_{i,j}(n-t) \) like in Theorem 4.1.

By Lemma 10.11 we have that

\[
\varphi_L(D_{a;i,j}^{(r)}) = 1 \otimes D_{a;i,j}^{(r)} + \delta_{a,m} \sum_{k=1}^{t} \tilde{e}_{i,k} \otimes \hat{D}_{a;k,j}^{(r-1)},
\]

\[
\varphi_L(E_{a;i,j}^{(r)}) = 1 \otimes E_{a;i,j}^{(r)} + \delta_{a,m-1} \sum_{k=1}^{t} \tilde{e}_{i,k} \otimes \hat{E}_{a;k,j}^{(r-1)},
\]

\[
\varphi_L(F_{a;i,j}^{(r)}) = 1 \otimes F_{a;i,j}^{(r)}.
\]

If we identify \( Y_{n,l-1}(\hat{\pi}) \) with \( W(\hat{\pi}) \subseteq U(\hat{p}) \) using the induction hypothesis, these are the same as the images of the corresponding elements of \( Y_{n,l}(\pi) \) under the baby comultiplication \( \Delta_L \) from Theorem 4.1(ii). So now the proof of the induction step in the case \( \Delta_L \) can be completed like before. Theorem 10.11 is proved.

11. Grown-up comultiplication

Fix a pyramid \( \pi \) of height \( \leq n \) with column heights \( (q_1, \ldots, q_l) \). Throughout the section, we will work with the numbering of the bricks of \( \pi \) down columns from left to right. Define \( p, h, m \) and \( e \) from (4.3), and let \( W(\pi) := U(p)^m \) be the corresponding finite \( W \)-algebra. Suppose we are given \( \ell', \ell'' \geq 0 \) with \( \ell' + \ell'' = l \). Let \( \pi' \) and \( \pi'' \) denote the pyramids consisting just of the leftmost \( \ell' \) and the rightmost \( \ell'' \) columns of \( \pi \), respectively. We write \( \pi = \pi' \otimes \pi'' \) whenever a pyramid is split in this way; for example,

\[
\begin{array}{cccc}
4 & 5 & 8 & 2 \\
1 & 3 & 7 & 10 & 11 \\
2 & 6 & 9 & \\
\end{array}
\begin{array}{cccc}
4 & 5 & 1 & 1 \\
2 & 6 & 2 & \\
1 & 3 & 4 & \\
\end{array}
\begin{array}{cccc}
1 & 2 & 2 & 1 \\
\end{array}
\]

\[
\begin{array}{cccc}
1 & 3 & 7 & 10 & 11 \\
\otimes & 3 & 4 & \\
\end{array}
= \begin{array}{cccc}
1 & 3 & 7 & 10 & 11 \\
\otimes & 3 & 4 & \\
\end{array}
= \begin{array}{cccc}
1 & 2 & 2 & 1 \\
\otimes & 3 & 4 & \\
\end{array}
= \begin{array}{cccc}
1 & 2 & 2 & 1 \\
\otimes & 3 & 4 & \\
\end{array}
\]

Let \( p', m', e' \) and \( p'', m'', e'' \) be defined from the pyramids \( \pi' \) and \( \pi'' \) inside the Lie algebras \( g' = gl_{N'} \) and \( g'' = gl_{N''} \), respectively. So \( N = N' + N'' \). Let \( W(\pi') = U(p')^{m'} \) and \( W(\pi'') = U(p'')^{m''} \). Recall also the elements \( \tilde{e}_{i,j} \) of \( U(p), U(p') \) and \( U(p'') \) defined
by (9.2) working with the pyramids \( \pi, \pi' \text{ and } \pi'' \), respectively. Define a homomorphism \( \Delta_{\pi,\pi'} : U(p) \to U(p') \otimes U(p'') \) by declaring that

\[
\Delta_{\pi,\pi'}(\tilde{e}_{i,j}) = \begin{cases} 
\tilde{e}_{i,j} \otimes 1 & \text{if } \text{col}(j) \leq l', \\
0 & \text{if } \text{col}(i) \leq l', l' + 1 \leq \text{col}(j), \\
1 \otimes \tilde{e}_{i-N',-N'} & \text{if } l' + 1 \leq \text{col}(i),
\end{cases}
\]

(11.1)

for all \( 1 \leq i, j \leq N \) with \( \text{col}(i) \leq \text{col}(j) \). This map is obviously filtered with respect to the Kazhdan filtrations. The following lemma describes the effect of \( \Delta_{\pi,\pi'} \) in terms of the elements \( T_{i,j} \) of \( U(p), U(p') \text{ and } U(p'') \) defined as in (9) again working with the pyramids \( \pi, \pi' \text{ and } \pi'' \) respectively. This should be compared with (4.1).

**Lemma 11.1.** For \( 1 \leq i, j \leq n \) and \( r > 0 \), \( \Delta_{\pi,\pi'}(T_{i,j}^{(r)}) = \sum_{s=0}^{r} \sum_{k=1}^{n} T_{i,k;0}^{(s)} \otimes T_{k,j;0}^{(r-s)} \).

**Proof.** Clear from (9.5). \( \square \)

One should visualize the map \( \Delta_{\pi,\pi'} \) as follows. The standard embedding of \( g' \oplus g'' \) into \( g \) also embeds \( p' \oplus p'' \) into \( p \) and \( m' \oplus m'' \) into \( m \). Then the map \( \Delta_{\pi,\pi'} \) is just induced by the obvious projection \( p \to p' \oplus p'' \) followed by a constant shift. The character \( \chi' \oplus \chi'' \) of \( m' \oplus m'' \) defined by taking the trace form with \( e' + e'' \) is the restriction of the character \( \chi \) of \( m \). So the map \( \Delta_{\pi,\pi'} \) sends twisted \( m \)-invariants in \( U(p) \) to twisted \( (m' \oplus m'') \)-invariants in \( U(p') \otimes U(p'') \). This shows that the restriction of \( \Delta_{\pi,\pi'} \) defines an algebra homomorphism

\[
\Delta_{\pi,\pi'} : W(\pi) \to W(\pi') \otimes W(\pi''),
\]

(11.2)

which is again a filtered map with respect to the Kazhdan filtrations. This defines a comultiplication \( \Delta_{\pi,\pi'} \) between the finite \( W \)-algebras which is coassociative in the following sense:

**Lemma 11.2.** If \( \pi = \pi' \oplus \pi'' \oplus \pi''' \) is a pyramid, where \( \pi', \pi'' \text{ and } \pi''' \) are of levels \( l', l'' \text{ and } l''' \) respectively, then the following diagram commutes:

\[
\begin{array}{ccc}
W(\pi') \otimes W(\pi'') \otimes W(\pi''') & \rightarrow & W(\pi') \otimes W(\pi'') \otimes W(\pi''') \\
\Delta_{\pi,\pi'+\pi''} \downarrow & & \downarrow \Delta_{\pi,\pi''} \otimes 1 \\
W(\pi') \otimes W(\pi'') \otimes W(\pi''') & \rightarrow & W(\pi') \otimes W(\pi'') \otimes W(\pi''')
\end{array}
\]

**Proof.** Obvious from (11.1). \( \square \)

Read off a shift matrix \( \sigma = (s_{i,j})_{1 \leq i, j \leq n} \) from the pyramid \( \pi \) according to (7.6). From now on we will identify the algebra \( W(\pi) \) with the shifted Yangian \( Y_{n,l}(\sigma) \) of level \( l \) using the isomorphism from Theorem 10.1. Let \( t := \min(q_1, q_l) \). Suppose first that the baby comultiplication \( \Delta_R : Y_{n,l}(\sigma) \to Y_{n,l-1}(\sigma) \otimes U(gl_t) \) is defined, i.e. either \( t = n \) or \( s_{n-t,n-t+1} \neq 0 \). The pyramid corresponding to the level \( (l-1) \) and the shift matrix \( \tilde{\sigma} \) here (which is defined by (11.5)) is simply the pyramid \( \pi' \) obtained from \( \pi \) by removing the rightmost column. So, identifying \( Y_{n,l-1}(\tilde{\sigma}) \) with \( W(\pi') \) according to Theorem 10.1 again, the map \( \Delta_R \) is therefore identified with a map \( \Delta_R : W(\pi) \to W(\pi') \otimes U(gl_t) \), just like the map \( \Delta_{l-1,l} \). Suppose instead that the baby comultiplication \( \Delta_L : Y_{n,l}(\sigma) \to U(gl_t) \otimes Y_{n,l-1}(\tilde{\sigma}) \) is defined, i.e. either \( t = n \) or \( s_{n-t,1,n-t} \neq 0 \). This time, the pyramid corresponding to the level \( (l-1) \)
and the shift matrix $\hat{\sigma}$ (defined now by (4.6)) is the pyramid $\pi''$ obtained from $\pi$ by removing the leftmost column. So $\Delta_L$ is identified with a map $W(\pi) \to U(\mathfrak{gl}_t) \otimes W(\pi'')$, just like the map $\Delta_{1,t-1}$.

**Lemma 11.3.** Whenever the baby comultiplications $\Delta_R$ and $\Delta_L$ are defined, they are equal to $\Delta_{1,1}$ and $\Delta_{1,t-1}$, respectively.

**Proof.** This is obvious in the case $l = 1$, so assume that $l > 1$. Assume the map $\Delta_R$ is defined. Comparing (11.4) with (10.7), it is clear that the map $\Delta_{l-1,1}$ coincides with the map $\varphi_R$ defined in the proof of Theorem 10.1. Comparing (10.8)–(10.10) with Theorem 11.1(i), the map $\varphi_R$ coincides with $\Delta_R$ under the identifications of $W(\pi)$ with $Y_{n,t}(\sigma)$ and $W(\pi')$ with $Y_{n,t-1}((\hat{\sigma}))$. Hence, $\Delta_{l-1,1} = \Delta_R$. The proof that $\Delta_{1,t-1} = \Delta_L$ is similar, using (10.14), (10.15)–(10.17) and Theorem 11.1(ii). \qed

If we iterate the comultiplication (in any order by coassociativity) a total of $(l - 1)$ times to split the pyramid $\pi$ into its individual columns, we obtain a homomorphism

$$\mu : W(\pi) \to U(\mathfrak{gl}_{q_1}) \otimes \cdots \otimes U(\mathfrak{gl}_{q_t}).$$

(11.3)

Let us give a direct description of this map. The elements $\{e_{i,j}^{[r]}\}_{1 \leq r \leq l, 1 \leq i, j \leq q_r}$ defined from $e_{i,j}^{[r]} := e_{q_1 + \cdots + q_{r-1} + i, q_1 + \cdots + q_{r-1} + j}$ form a basis for the subalgebra $\mathfrak{h}$ of $\mathfrak{p}$. Identify $U(\mathfrak{h})$ with $U(\mathfrak{gl}_{q_1}) \otimes \cdots \otimes U(\mathfrak{gl}_{q_t})$ so that $e_{i,j}^{[r]}$ is identified with $1^\otimes (r-1) \otimes e_{i,j} \otimes 1^\otimes (l-r)$. The map (11.3) is then identified with a homomorphism

$$\mu : W(\pi) \to U(\mathfrak{h})$$

(11.4)

which is a filtered map with respect to the Kazhdan filtration of $W(\pi)$ and the standard filtration of $F_\mathfrak{p}U(\mathfrak{h}) \subseteq F_1U(\mathfrak{h}) \subseteq \cdots$ of $U(\mathfrak{h})$; we will write $\text{gr } U(\mathfrak{h})$ for the associated graded algebra here. Let

$$\eta : U(\mathfrak{h}) \to U(\mathfrak{h}), \quad e_{i,j}^{[r]} \mapsto e_{i,j}^{[r]} + \delta_{i,j}(q_{r+1} + \cdots + q_t).$$

(11.5)

Let $\xi : U(\mathfrak{p}) \to U(\mathfrak{h})$ be the algebra homomorphism induced by the natural projection $\mathfrak{p} \to \mathfrak{h}$. Then, it is easy to see from (11.1) and (9.1) that $\mu$ is precisely the restriction of the map $\eta \circ \xi$ to $W(\pi)$. By analogy with the language used in [BT], we call $\mu$ the Miura transform; in [L] it is called the generalized Harish-Chandra homomorphism. The following result is due to Lynch [L, Corollary 2.3.2].

**Theorem 11.4.** The map $\text{gr } \mu : \text{gr } W(\pi) \to \text{gr } U(\mathfrak{h})$ is injective, hence so is the Miura transform $\mu : W(\pi) \to U(\mathfrak{h})$ itself.

**Proof.** By Lemma 11.3 and the definition (11.3), we can factor $\mu$ as a composition of $(l - 1)$ maps of the form $\Delta_R$ or $\Delta_L$. Now the theorem follows from the injectivity of $\text{gr } \Delta_R$ and $\text{gr } \Delta_L$ proved in Theorem 6.2. \qed

**Corollary 11.5.** The map $\text{gr } \Delta_{l',l''} : \text{gr } W(\pi) \to \text{gr } W(\pi') \otimes W(\pi'')$ is injective for any $l' + l'' = l$. Hence so is the comultiplication $\Delta_{l',l''} : W(\pi) \to W(\pi') \otimes W(\pi'')$.

**Proof.** We can factor $\mu$ as a composition of $\Delta_{l',l''}$ followed by $(l - 2)$ more maps. \qed

For the next lemma, we recall from Corollary 10.3 that if $\pi$ and $\hat{\pi}$ are two pyramids with the same row lengths, then there is a canonical isomorphism $\iota : W(\pi) \to W(\hat{\pi})$. The following lemma shows that the comultiplication is compatible with these isomorphisms.
Lemma 11.6. Suppose that \( \pi = \pi' \otimes \pi'' \) and \( \hat{\pi} = \hat{\pi}' \otimes \hat{\pi}'' \) are pyramids such that \( \hat{\pi}' \) and \( \hat{\pi}'' \) have the same row lengths as \( \pi' \) and \( \pi'' \), respectively. Then the following diagram commutes:

\[
\begin{array}{ccc}
W(\pi) & \xrightarrow{\Delta'_l \otimes \Delta''_l} & W(\pi') \otimes W(\pi'') \\
\downarrow & & \downarrow \otimes \downarrow \\
W(\hat{\pi}) & \xrightarrow{\Delta'_l \otimes \Delta''_l} & W(\hat{\pi}') \otimes W(\hat{\pi}'')
\end{array}
\]

where \( \pi' \) and \( \pi'' \) are of levels \( l' \) and \( l'' \), respectively.

Proof. Proceed by induction on \( l = l' + l'' \). If either \( l' = 0 \) or \( l'' = 0 \), the statement of the lemma is vacuous, so the base case \( l = 1 \) is trivial. Now suppose that \( l', l'' > 0 \), so \( l > 1 \), and that the lemma has been proved for all smaller levels. Read off a shift matrix \( \sigma \) from the pyramid \( \pi \) and identify \( W(\pi) \) with \( Y_{n,l}(\sigma) \) as usual. At least one of the baby comultiplications \( \Delta_R \) and \( \Delta_L \) from (3.21) is always defined; we explain the proof of the induction step just in the case that \( \Delta_R \) is defined, the argument being entirely similar in the other case. Also read off a shift matrix \( \tilde{\sigma} \) from the pyramid \( \hat{\pi} \) and identify \( W(\hat{\pi}) \) with \( Y_{n,l}(\tilde{\sigma}) \); we can ensure in doing this that the baby comultiplication \( \Delta_R \) is defined for \( Y_{n,l}(\tilde{\sigma}) \) too.

Suppose first that \( l'' = 1 \). Then by Lemma 11.3, \( \Delta''_l \otimes \Delta^l \) is equal in either case to the map \( \Delta_R \), and the commutativity of the diagram is easy to check explicitly on generators of \( W(\pi) \), using (3.21) and Theorem 4.1(i).

Now suppose that \( l'' > 1 \). Let \( \rho, \hat{\rho}, \rho' \) and \( \hat{\rho}' \) denote the pyramids obtained from \( \pi, \hat{\pi}, \pi'' \) and \( \hat{\pi}'' \), respectively, by removing the rightmost column (which is of height \( q_l \) in all cases). Consider the following cube

\[
\begin{array}{ccc}
W(\hat{\pi}) & \longrightarrow & W(\hat{\rho}) \otimes U(gl_{q_l}) \\
W(\pi) & \rightarrow & W(\rho) \otimes U(gl_{q_l}) \\
\downarrow & & \downarrow \\
W(\hat{\pi}') \otimes W(\hat{\pi}'') & \longrightarrow & W(\hat{\rho}') \otimes W(\hat{\rho}'') \otimes U(gl_{q_l}) \\
W(\pi') \otimes W(\pi'') & \rightarrow & W(\pi') \otimes W(\pi') \otimes U(gl_{q_l})
\end{array}
\]

where the maps on the front and back faces are defined from the comultiplications, and the remaining maps are isomorphisms built from \( \iota \). The front and back faces commute by Lemma 11.2. The top and bottom faces commute by the special case considered in the preceding paragraph. The right hand face commutes by the induction hypothesis. Since the comultiplication map \( W(\hat{\pi}') \otimes W(\hat{\pi}'') \rightarrow W(\hat{\rho}') \otimes W(\hat{\rho}'') \otimes U(gl_{q_l}) \) is injective by Corollary 11.5, it therefore follows that the left face commutes too. This completes the proof of the induction step. \( \square \)

In the remainder of the section, we are going to lift the comultiplication to the shifted Yangian \( Y_n(\sigma) \) itself. First, we must explain one other basic operation on pyramids, that of column removal. Let \( 1 \leq i_1 < \cdots < i_l \leq l \) be some subset of the columns of the pyramid \( \pi \), and let \( \pi \) be the pyramid with column heights \( (q_{i_1}, \ldots, q_{i_l}) \). We can read
off shift matrices \( \sigma = (s_{i,j})_{1 \leq i,j \leq n} \) and \( \hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n} \) from the pyramids \( \pi \) and \( \pi' \) respectively in such a way as to ensure \( \hat{s}_{i,j} \leq s_{i,j} \) for all \( 1 \leq i,j \leq n \). Hence embedding \( Y_n(\sigma) \) and \( Y_n(\hat{\sigma}) \) into \( Y_n \) in the canonical way, we have that \( Y_n(\sigma) \subseteq Y_n(\hat{\sigma}) \). This inclusion \( Y_n(\sigma) \hookrightarrow Y_n(\hat{\sigma}) \) factors through the quotients to induce a map

\[
\zeta : Y_{n,l}(\sigma) \to Y_{n,l}(\hat{\sigma}).
\]  

(11.6)

Equivalently, identifying \( Y_{n,l}(\sigma) \) with \( W(\pi) \) and \( Y_{n,l}(\hat{\sigma}) \) with \( W(\hat{\pi}) \) by Theorem \( \ref{thm:correspondence} \), this defines a homomorphism

\[
\zeta : W(\pi) \to W(\hat{\pi})
\]  

(11.7)

sending the generators \( D_i^{(r)}, E_i^{(r)} \) and \( F_i^{(r)} \) of \( W(\pi) \) to the elements \( \hat{D}_i^{(r)}, \hat{E}_i^{(r)} \) and \( \hat{F}_i^{(r)} \) of \( W(\hat{\pi}) \), respectively. In order to understand the relationship between this “column removal homomorphism” \( \zeta \) and the comultiplication, we need another description of \( \zeta \). Let \( \mu : W(\pi) \to U(\mathfrak{h}) \) and \( \hat{\mu} : W(\hat{\pi}) \to \hat{U}(\hat{\mathfrak{h}}) \) be the Miura transforms defined by (11.4). There is an obvious projection \( \hat{\zeta} : \mathfrak{h} \to \hat{\mathfrak{h}} \) defined by

\[
\hat{\zeta}(e_{i,j}^{[r]}) = \begin{cases} 
  e_{i,j} & \text{if } r = i_s \text{ for some } s = 1, \ldots, \hat{l}, \\
  0 & \text{otherwise}.
\end{cases}
\]

**Lemma 11.7.** With the above notation, the following diagram commutes

\[
\begin{array}{ccc}
W(\pi) & \xrightarrow{\mu} & U(\mathfrak{h}) \\
\downarrow{\zeta} & & \downarrow{\hat{\zeta}} \\
W(\hat{\pi}) & \xrightarrow{\hat{\mu}} & \hat{U}(\hat{\mathfrak{h}})
\end{array}
\]

*Proof.* One checks explicitly from Corollary 9.4 and the definition (9.5) that \( \hat{\zeta} \) maps the elements \( \mu(D_i^{(r)}), \mu(E_i^{(r)}) \) and \( \mu(F_i^{(r)}) \) to \( \hat{\mu}(\hat{D}_i^{(r)}), \hat{\mu}(\hat{E}_i^{(r)}) \) and \( \hat{\mu}(\hat{F}_i^{(r)}) \). \( \Box \)

**Corollary 11.8.** Suppose that \( \pi = \pi' \otimes \pi'' \) and \( \hat{\pi} = \hat{\pi}' \otimes \hat{\pi}'' \), where \( \pi' \) and \( \pi'' \) are obtained by removing columns from the pyramids \( \pi' \) and \( \pi'' \), respectively. Then, the following diagram commutes

\[
\begin{array}{ccc}
W(\pi) & \xrightarrow{\Delta_{\pi',\pi''}} & W(\pi') \otimes W(\pi'') \\
\downarrow{\zeta} & & \downarrow{\zeta \otimes \zeta} \\
W(\hat{\pi}) & \xrightarrow{\Delta_{\hat{\pi}',\hat{\pi}''}} & W(\hat{\pi}') \otimes W(\hat{\pi}'')
\end{array}
\]

where \( \pi', \pi'' \) are of widths \( l', l'' \) and \( \hat{\pi}', \hat{\pi}'' \) are of widths \( \hat{l}', \hat{l}'' \).

*Proof.* In view of Lemma 11.7 and the injectivity of the Miura transforms, this follows from the commutativity of the following diagram:

\[
\begin{array}{ccc}
U(\mathfrak{h}) & \xrightarrow{\sim} & U(\mathfrak{h}') \otimes U(\mathfrak{h}'') \\
\downarrow{\hat{\zeta}} & & \downarrow{\hat{\zeta} \otimes \hat{\zeta}} \\
U(\hat{\mathfrak{h}}) & \xrightarrow{\sim} & U(\hat{\mathfrak{h}}') \otimes U(\hat{\mathfrak{h}}'')
\end{array}
\]

where the horizontal maps are induced by the obvious isomorphisms \( \mathfrak{h} \cong \mathfrak{h}' \oplus \mathfrak{h}'' \) and \( \hat{\mathfrak{h}} \cong \hat{\mathfrak{h}}' \oplus \hat{\mathfrak{h}}'' \). \( \Box \)
Now we can prove the main theorem of the section:

**Theorem 11.9.** Let \( \sigma \) be a shift matrix and write \( \sigma = \sigma' + \sigma'' \) where \( \sigma' \) is strictly lower triangular and \( \sigma'' \) is strictly upper triangular. Embedding \( Y_n(\sigma), Y_n(\sigma') \) and \( Y_n(\sigma'') \) into \( Y_n \) in the standard way, the restriction of the comultiplication \( \Delta : Y_n \to Y_n \otimes Y_n \) gives a homomorphism

\[
\Delta : Y_n(\sigma) \to Y_n(\sigma') \otimes Y_n(\sigma'').
\]

Moreover, for \( l' \geq s_{n,1}, l'' \geq s_{1,n} \) and \( l = l' + l'' \), this map \( \Delta \) factors through the quotients to define a homomorphism \( Y_{n,l}(\sigma) \to Y_{n,l'}(\sigma') \otimes Y_{n,l''}(\sigma'') \) which, on identifying \( Y_{n,l}(\sigma) \) with \( W(\pi), Y_{n,l'}(\sigma') \) with \( W(\pi') \) and \( Y_{n,l''}(\sigma'') \) with \( W(\pi'') \) as usual, is precisely the comultiplication \( \Delta_{l',l''} \) from (11.2).

**Proof.** Start from the map \( \Delta_{l',l''} : Y_{n,l}(\sigma) \to Y_{n,l'}(\sigma') \otimes Y_{n,l''}(\sigma'') \) from (11.2). Recall from Remark 6.4 how \( Y_n(\sigma), Y_n(\sigma') \) and \( Y_n(\sigma'') \) are identified with the inverse limits \( \lim_{l'} Y_{n,l}(\sigma), \lim_{l'} Y_{n,l'}(\sigma') \) and \( \lim_{l''} Y_{n,l''}(\sigma'') \), respectively. Corollary 11.8 is exactly what is needed to ensure that the maps \( \Delta_{l',l''} \) are stable as \( l', l'' \to \infty \). Hence there is an induced homomorphism \( \lim_{l'} \Delta_{l',l''} : Y_n(\sigma) \to Y_n(\sigma') \otimes Y_n(\sigma'') \) lifting the maps \( \Delta_{l',l''} \) for all \( l' \geq s_{n,1}, l'' \geq s_{1,n} \). Now we just need to show that this map \( \lim_{l'} \Delta_{l',l''} \) agrees with the restriction of the comultiplication \( \Delta \) on \( Y_n \).

Let \( X \) be some generator \( D_i^{(r)}, E_i^{(r)} \) or \( F_i^{(r)} \) of \( Y_n(\sigma) \subseteq Y_n \). Consider how one computes \( \Delta(X) \) in practice: first one expresses \( X \) as a linear combination of monomials in the \( T_{i,j}^{(r)} \) as explained in [3] (see also the explicit formulæ [BK] (5.2)-(5.4)); then one computes \( \Delta(X) \) in terms of \( T_{h,k}^{(s)} \)'s using the definition (11.1); finally one rewrites all \( T_{h,k}^{(s)} \) appearing in the resulting expression back in terms of the generators \( D_i^{(r)}, E_i^{(r)} \) and \( F_i^{(r)} \). But in view of Lemma 11.11 exactly the same procedure may be used to compute the effect of \( \Delta_{l',l''} \) on the image of \( X \) in \( Y_{n,l}(\sigma) \) for each \( l \). The point is that the formula expressing \( T_{i,j}^{(r)} \) in terms of the elements \( D_i^{(r)}, E_i^{(r)} \) and \( F_i^{(r)} \) of \( U(p) \) explained in [3] is identical to the formula doing the same thing in \( Y_n \) explained in [3]. It follows that \( \Delta = \lim_{l'} \Delta_{l',l''} \).

**Remark 11.10.** Using Theorem 11.9 and Lemma 11.6, one can express all of the comultiplications \( \Delta_{l',l''} : W(\pi) \to W(\pi') \otimes W(\pi'') \) in terms of the comultiplication \( \Delta \) of \( Y_n \), as follows. Let \( \tilde{\pi}' \) denote the right-justified pyramid with the same row lengths as \( \pi' \), and let \( \tilde{\pi}'' \) denote the left-justified pyramid with the same row lengths as \( \pi'' \). Let \( \tilde{\pi} := \tilde{\pi}' \otimes \tilde{\pi}'' \). By Lemma 11.6, the comultiplication \( \Delta_{l',l''} : W(\pi) \to W(\pi') \otimes W(\pi'') \) can be recovered from \( \Delta_{l',l''} : W(\tilde{\pi}) \to W(\tilde{\pi}') \otimes W(\tilde{\pi}'') \) using the isomorphisms \( \iota \). Finally \( \Delta_{l',l''} : W(\tilde{\pi}) \to W(\tilde{\pi}') \otimes W(\tilde{\pi}'') \) is one of the comultiplications described by Theorem 11.9.

To end the main part of the article, we record one corollary of Theorem 11.9. This gives an application of shifted Yangians to prove a result just involving the Yangian \( Y_n \) itself. For the statement, let \( Y_n^{(1)} \) resp. \( Y_n^{(0)} \) denote the Borel subalgebra of the Yangian \( Y_n \) generated by the \( D_i^{(r)} \)'s together with the \( E_i^{(r)} \)'s resp. the \( F_i^{(r)} \)'s.

**Corollary 11.11.** The comultiplication \( \Delta : Y_n \to Y_n \otimes Y_n \) has the following properties:

(i) \( \Delta(D_i^{(r)}) \in Y_n^{(2)}(1_n) \otimes Y_n^{(0)}(1_n) \);

(ii) \( \Delta(E_i^{(r)}) \in Y_n^{(2)}(1_n) \otimes Y_n^{(1)}(1_n) + \mathbb{C}(1 \otimes E_i^{(r)}) \).

(iii) $\Delta(F_i^{(r)}) \in Y_{(1^n)}^r \otimes Y_{(1^n)}^2 + \mathbb{C}(F_i^{(r)} \otimes 1)$.

**Proof.** (i) Let $\sigma = (s_{i,j})_{1 \leq i,j \leq n}$ be a shift matrix with $s_{j,j+1}, s_{j+1,j} \geq r$ for all $j = 1, \ldots, n - 1$. The element $D_i^{(r)}$ belongs to $Y_n(\sigma)$. Hence by the first part of Theorem 12.9, we know that $\Delta(D_i^{(r)})$ lies in the subalgebra $Y_n(\sigma') \otimes Y_n(\sigma'')$ of $Y_n \otimes Y_n$. Moreover, $\Delta$ is a filtered map with respect to the canonical filtration, hence in fact we have that $\Delta(D_i^{(r)}) \in \sum_{s=0}^r F_s Y_n(\sigma') \otimes F_{r-s} Y_n(\sigma'')$. But by the choice of $\sigma$, $F_s Y_n(\sigma') \subseteq Y_{(1^n)}^r$ and $F_{r-s} Y_n(\sigma'') \subseteq Y_{(1^n)}^2$ for all $s = 0, \ldots, r$, so we are done.

(ii) Similar, except one needs to take $s_{i,i+1} = r - 1$ in the shift matrix $\sigma$.

(iii) Similar. \qed

12. A SPECIAL CASE

In this section, we give a much more direct proof of the main results of the article in the special case that the nilpotent matrix $e$ consists of $n$ Jordan blocks all of the same size $l$, i.e. the pyramid $\pi$ is an $n \times l$ rectangle and $N = nl$. The main theorem in this case was first noticed by Ragoucy and Sorba [RS]; see also [BR] which is closer to the present exposition. We will identify $\mathfrak{g} = \mathfrak{gl}_N$ with the tensor product $\mathfrak{gl}_l \otimes \mathfrak{gl}_l$, so that the matrix unit $e_{(r-1)n+i,(s-1)n+j} \in \mathfrak{gl}_N$ is identified with $e_{r,s} \otimes e_{i,j} \in \mathfrak{gl}_l \otimes \mathfrak{gl}_l$ for $1 \leq r, s \leq l$, $1 \leq i, j \leq n$. Numbering the bricks of the pyramid $\pi$ down columns from left to right as usual, the $\mathfrak{sl}_2$-triple $(e, h, f)$ introduced at the beginning of [RS] is given explicitly in this case by

$$e = \sum_{r=1}^{l-1} e_{r,r+1} \otimes I_n, \quad h = \sum_{r=1}^{l} (l + 1 - 2r)e_{r,r} \otimes I_n, \quad f = \sum_{r=1}^{l-1} r(l - r)e_{r+1,r} \otimes I_n.$$ 

Let $M_n$ denote the algebra of $n \times n$ matrices over $\mathbb{C}$ and let $T(\mathfrak{gl}_l)$ denote the tensor algebra on the vector space $\mathfrak{gl}_l$. Define an algebra homomorphism

$$T : T(\mathfrak{gl}_l) \rightarrow M_n \otimes U(\mathfrak{gl}_N)$$

(12.1)

sending a generator $x \in \mathfrak{gl}_l$ to $T(x) = \sum_{i,j=1}^n e_{i,j} \otimes (x \otimes e_{i,j}) \in M_n \otimes U(\mathfrak{gl}_N)$. Also define maps

$$T_{i,j} : T(\mathfrak{gl}_l) \rightarrow U(\mathfrak{gl}_N)$$

(12.2)

for each $1 \leq i, j \leq n$ from the equation $T(x) = \sum_{i,j=1}^n e_{i,j} \otimes T_{i,j}(x)$, for any $x \in T(\mathfrak{gl}_l)$. Thus, thinking of $T(x)$ as an $n \times n$ matrix with entries in $U(\mathfrak{gl}_N)$, $T_{i,j}(x)$ is the $ij$-entry of $T(x)$. We have by definition that $T(xy) = T(x)T(y)$ for any $x, y \in T(\mathfrak{gl}_l)$, which implies that

$$T_{i,j}(xy) = \sum_{k=1}^n T_{i,k}(x)T_{k,j}(y).$$

(12.3)

In particular, $T_{i,j}(1) = \delta_{i,j}$ and

$$T_{i,j}(x_1 \otimes \cdots \otimes x_r) = \sum_{1 \leq i_0,i_1,\ldots,i_r \leq n \atop i_0 = i_r,j = j} (x_1 \otimes e_{i_0,i_1})(x_2 \otimes e_{i_1,i_2}) \cdots (x_r \otimes e_{i_{r-1},i_r})$$

(12.4)

for arbitrary $x_1, \ldots, x_r \in \mathfrak{gl}_l$. If $u$ is an indeterminate, we will also write $T_{i,j}$ for the map obtained from $T_{i,j}$ by extending scalars from $\mathbb{C}$ to $\mathbb{C}[u]$. 

Lemma 12.1. For $1 \leq h, i, j, k \leq n$ and $x, y_1, \ldots, y_r \in \mathfrak{gl}_l$,

$$[T_{i,j}(x), T_{h,k}(y_1 \otimes \cdots \otimes y_r)] = \sum_{s=1}^{r} T_{h,j}(y_1 \otimes \cdots \otimes y_{s-1}) T_{i,k}(x y_s \otimes y_{s+1} \otimes \cdots \otimes y_r)$$

$$- \sum_{s=1}^{r} T_{h,j}(y_1 \otimes \cdots \otimes y_{s-1} \otimes y_s x) T_{i,k}(y_{s+1} \otimes \cdots \otimes y_r),$$

where $x y_s$ and $y_s x$ denote the usual products of matrices in $M_l$.

Proof. Use (12.3) and induction on $r$. □

Define $\Omega(u)$ to be the following $l \times l$ matrix with entries in $T(\mathfrak{gl}_l)[u]$:

$$\Omega(u) := \begin{pmatrix}
            e_{1,1} + u + \rho_1 & e_{1,2} & e_{1,3} & \cdots & e_{1,l} \\
            1 & e_{2,2} + u + \rho_2 & \vdots \\
            0 & \ddots & & \ddots & e_{l-2,l} \\
            \vdots & & 1 & e_{l-1,l-1} + u + \rho_{l-1} & e_{l-1,l} \\
            0 & \cdots & 0 & 1 & e_{l,l} + u + \rho_l
          \end{pmatrix}$$

where $\rho_r = -(l-r)n$ as in (9.1). Define the row-wise determinant of an $l \times l$ matrix $A = (a_{i,j})$ with entries in a non-commutative ring $R$ by the formula

$$\text{rdet } A = \sum_{\pi \in S_l} \text{sgn}(\pi) a_{1,\pi_1} \cdots a_{l,\pi_l}.$$

(12.5)

Then $\text{rdet } \Omega(u)$ makes sense as an element of $T(\mathfrak{gl}_l)[u]$. Now we use the maps (12.2) to define

$$T_{i,j}(u) = \sum_{r=0}^{l} T_{i,j}^{(r)} u^{l-r} := T_{i,j}(\text{rdet } \Omega(u))$$

(12.6)

for each $i, j = 1, \ldots, n$. It is easy to see for $r = 0, 1, \ldots, l$ that $T_{i,j}^{(r)}$ is precisely the element $T_{i,j}^{(r)}$ of $F_r U(p)$ defined in (9.6). We also set $T_{i,j}^{(r)} := 0$ for $r > l$. In the next lemma, we check directly that these elements belong to the algebra $W(\pi) = U(p)^m$ introduced in §8.

Lemma 12.2. For each $1 \leq i, j \leq n$ and $r > 0$, $T_{i,j}^{(r)}$ is invariant under the twisted action of $m$.

Proof. Since $m$ is generated by elements of the form $e_{r+1,r} \otimes e_{i,j}$, it suffices to show that $\text{pr}_\chi([T_{i,j}(e_{r+1,r}), T_{h,k}(\text{rdet } \Omega(u))]) = 0$ for every $1 \leq h, i, j, k \leq n$ and $r = 1, \ldots, l - 1$. Let us write $\Omega_{r,s}(u)$ for the submatrix of $\Omega(u)$ consisting only of rows and columns
numbered $r, \ldots, s$. We compute using Lemma 12.1 to get that
\[
[T_{i,j}(e_{r+1,r}), T_{h,k}(\det \Omega(u))] = T_{h,j}(\det \Omega_{1,r-1}(u)) \times 
\]
\[
T_{i,k} \begin{pmatrix}
\det \begin{pmatrix}
e_{r+1,r} & e_{r+1,r+1} & \cdots & e_{r+1,l} \\
1 & e_{r+1,r+1} + u + \rho_l & \cdots & e_{r+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & e_{l,l} + u + \rho_l
\end{pmatrix} \\
e_{1,1} + u + \rho_1 & \cdots & e_{1,r} & e_{1,r} \\
1 & \ddots & \vdots & \vdots \\
\vdots & e_{r,r} + u + \rho_r & e_{r,r} & 0 & \cdots & 1 & e_{r+1,r}
\end{pmatrix}
\end{pmatrix}
\]
\[
- T_{h,j} \begin{pmatrix}
\det \begin{pmatrix}
e_{1,1} + u + \rho_1 & \cdots & e_{1,r} & e_{1,r} \\
1 & \ddots & \vdots & \vdots \\
\vdots & e_{r,r} + u + \rho_r & e_{r,r} & 0 & \cdots & 1 & 1
\end{pmatrix}
\end{pmatrix}
\]

In order to apply $\text{pr}_\chi$ to the right hand side, we observe that for any $1 \leq m \leq n$,
\[
\text{pr}_\chi(T_{i,m}(e_{r+1,r} e_{r+1,r+1} + u + \rho_r)) = T_{i,m}(e_{r+1,r+1} + u + \rho_r).
\]
Hence, we get that
\[
\text{pr}_\chi([T_{i,j}(e_{r+1,r}), T_{h,k}(\det \Omega(u))]) = T_{h,j}(\det \Omega_{1,r-1}(u)) \times 
\]
\[
T_{i,k} \begin{pmatrix}
\det \begin{pmatrix}
e_{r+1,r} & e_{r+1,r+1} & \cdots & e_{r+1,l} \\
1 & e_{r+1,r+1} + u + \rho_r & \cdots & e_{r+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & e_{l,l} + u + \rho_l
\end{pmatrix} \\
e_{1,1} + u + \rho_1 & \cdots & e_{1,r} & e_{1,r} \\
1 & \ddots & \vdots & \vdots \\
\vdots & e_{r,r} + u + \rho_r & e_{r,r} & 0 & \cdots & 1 & 1
\end{pmatrix}
\end{pmatrix}
\]
\[
- T_{h,j} \begin{pmatrix}
\det \begin{pmatrix}
e_{1,1} + u + \rho_1 & \cdots & e_{1,r} & e_{1,r} \\
1 & \ddots & \vdots & \vdots \\
\vdots & e_{r,r} + u + \rho_r & e_{r,r} & 0 & \cdots & 1 & 1
\end{pmatrix}
\end{pmatrix}
\]

Making the obvious row and column operations gives that
\[
\det \begin{pmatrix}
1 & e_{r+1,r+1} & \cdots & e_{r+1,l} \\
1 & e_{r+1,r+1} + u + \rho_r & \cdots & e_{r+1,l} \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & e_{l,l} + u + \rho_l
\end{pmatrix} = (u + \rho_r) \det \Omega_{r+2,l}(u),
\]
\[
\det \begin{pmatrix}
e_{1,1} + u + \rho_1 & \cdots & e_{1,r} & e_{1,r} \\
1 & \ddots & \vdots & \vdots \\
\vdots & e_{r,r} + u + \rho_r & e_{r,r} & 0 & \cdots & 1 & 1
\end{pmatrix} = (u + \rho_r) \det \Omega_{1,r-1}(u).
\]

Now substituting these into the above formula for $\text{pr}_\chi([T_{i,j}(e_{r+1,r}), T_{h,k}(\det \Omega(u))])$ shows that it is zero. □
Denoting the matrix unit \( e_{r,s} \otimes e_{i,j} \) instead by \( e_{i,j}^{[r]} \), the subalgebra \( \mathfrak{h} \cong \mathfrak{gl}_n \) of \( \mathfrak{g} \) has basis \( \{ e_{i,j}^{[r]} \}_{1 \leq r \leq l, 1 \leq i,j \leq n} \). Let

\[
\eta : U(\mathfrak{h}) \to U(\mathfrak{h}), \quad e_{i,j}^{[r]} \mapsto e_{i,j}^{[r]} + \delta_{i,j}(l-r)n. \tag{12.7}
\]

Let \( \xi : U(\mathfrak{p}) \to U(\mathfrak{h}) \) be the algebra homomorphism induced by the natural projection \( \mathfrak{p} \to \mathfrak{h} \). The composite \( \mu := \eta \circ \xi \) is precisely the Miura transform from \([11.3]\).

**Lemma 12.3.** For \( 1 \leq i, j \leq n \) and \( r > 0 \), the Miura transform \( \mu \) maps the element \( T_{i,j}^{(r)} \) of \( U(\mathfrak{p}) \) to the element

\[
\sum_{1 \leq s_1 < \cdots < s_r \leq l, 1 \leq i_0, i_r \leq n} e_{i_0,i_1}^{[s_1]} e_{i_1,i_2}^{[s_2]} \cdots e_{i_{r-1},i_r}^{[s_r]} \tag{12.8}
\]

of \( U(\mathfrak{h}) \).

*Proof.* Applying the map \( e_{r,s} \mapsto \delta_{r,s}(e_{r,s} + (l-r)n) \) to the matrix \( \Omega(u) \) gives a diagonal matrix with determinant \( (u+e_{1,1})(u+e_{2,2}) \cdots (u+e_{r,r}) \). The \( u^{l-r} \)-coefficient of this is the (non-commutative) elementary symmetric function \( \sum_{1 \leq s_1 < \cdots < s_r \leq l} e_{s_1,s_1} \cdots e_{s_r,s_r} \). Now the lemma follows from \([12.4]\). \( \square \)

Finally let \( Y_{n,l} \) denote the Yangian of level \( l \) from \([C2]\). This may be defined as the algebra on generators \( \{ T_{i,j}^{(r)} \}_{1 \leq i,j \leq n, r \geq 0} \) subject to the relations \([3.1]\) and in addition \( T_{i,j}^{(r)} = 0 \) for all \( 1 \leq i, j \leq n \) and \( r > l \). We will work now with the canonical filtration on \( Y_{n,l} \) and the Kazhdan filtration of \( W(\pi) \), as defined in sections \(5\) and \(8\) respectively. The main theorem in our special case is as follows.

**Theorem 12.4.** There is an isomorphism \( Y_{n,l} \cong W(\pi) \) of filtered algebras such that the generators \( \{ T_{i,j}^{(r)} \}_{1 \leq i,j \leq n, r \geq 0} \) of \( Y_{n,l} \) map to the elements of \( W(\pi) \) with the same names. Moreover, the Miura transform \( \mu : W(\pi) \to U(\mathfrak{h}) \) is injective, and the map \( \theta \) from the diagram \([8.4]\) is an isomorphism.

*Proof.* By the PBW theorem for \( Y_{n,l} \) from \([BK1\] Theorem 3.1) (which is due originally to Cherednik \([C1\], \[C2\]) the set of all monomials in the elements \( \{ T_{i,j}^{(r)} \}_{1 \leq i,j \leq n, 1 \leq r \leq l} \) taken in some fixed order and of total degree \( \leq d \) form a basis for \( F_d Y_{n,l} \). Moreover, shows that there is an injective algebra homomorphism \( \kappa_l : Y_{n,l} \to U(\mathfrak{h}) \) mapping \( T_{i,j}^{(r)} \in Y_{n,l} \) to precisely the element \([12.8]\). We also note from Lemma \([7.8]\) that for each \( d \geq 0 \),

\[
\dim \kappa_l(F_d Y_{n,l}) = \dim F_d Y_{n,l} = \dim F_d S(\mathfrak{c}_g(e)), \tag{12.9}
\]

where \( F_d S(\mathfrak{c}_g(e)) \) denotes the sum of all the graded pieces of \( S(\mathfrak{c}_g(e)) \) of degree \( \leq d \) for the Kazhdan grading.

Let \( X_d \) denote the subspace of \( U(\mathfrak{p}) \) spanned by all monomials in the elements \( \{ T_{i,j}^{(r)} \}_{1 \leq i,j \leq n, 0 \leq r \leq l} \) taken in some fixed order and of total degree \( \leq d \). By Lemma \([12.3]\) and the previous paragraph, \( \mu(X_d) = \kappa_l(F_d Y_{n,l}) \). Hence, since we know by Lemma \([12.2]\) that \( X_d \subset F_d W(\pi) \), we get by \([12.9]\) and Corollary \([8.3]\) that

\[
\dim F_d S(\mathfrak{c}_g(e)) = \dim \mu(X_d) \leq \dim X_d \leq \dim F_d W(\pi) \leq \dim F_d S(\mathfrak{c}_g(e)).
\]
Hence equality holds everywhere, which means that $X_d = F_dW(\pi)$, the Miura transform $\mu$ is injective with the same image as $\kappa_l$, and the map $\theta$ is an isomorphism. Hence the composite $\mu^{-1} \circ \kappa_l$ gives the required isomorphism $Y_{n,l} \to W(\pi)$ of filtered algebras. \hfill \Box
