Abstract: In this article, we take into account the (2 + 1)-dimensional stochastic Chiral nonlinear Schrödinger equation (2D-SCNLSE) in the Itô sense by multiplicative noise. We acquired trigonometric, rational and hyperbolic stochastic exact solutions, using three vital methods, namely Riccati–Bernoulli sub-ODE, He’s variational and sine–cosine methods. These solutions may be applicable in various applications in applied science. The proposed methods are direct, efficient and powerful. Moreover, we investigate the effect of multiplicative noise on the solution for 2D-SCNLSE by introducing some graphs to illustrate the behavior of the obtained solutions.

Keywords: Chiral nonlinear Schrödinger equation; Riccati–Bernoulli sub-ODE method; variational principles; sine–cosine method; soliton solutions; multiplicative noise; physical applications

1. Introduction

Mathematical models of different phenomena in various areas of the physical sciences, including nonlinear optics, biology, economy, fluid mechanics and plasma physics, can be interpreted by nonlinear systems of nonlinear partial differential equations (NPDEs) [1–9]. Exact solutions of the NPDEs are crucial for the analysis of natural phenomena in a wide variety of physical sciences. Accordingly, a lot of methods have been proposed to get exact solutions for NPDEs; for instance, the \( (G'/G) \)-expansion method [10,11], sine–cosine method [12,13], the homotopy perturbation method [14], Hirota’s method [15], inverse scattering method [16], Petrov–Kudrin–Xiong method [17,18], perturbation method [19], the variational iteration method [20,21], Riccati–Bernoulli sub-ODE method [22,23], the tanh-sech method [24], the Jacobi elliptic function method [25], the \( \exp(-\phi) \)-expansion method [26].

The nonlinear Schrödinger equation (NLSE), which exhibits solitary type solutions, becomes the main representative way for describing wave behaviors in a nonlinear large number of applications, such as optics, quantum mechanics, biophysics, deep water, plasma physics, electro magnetic wave propagation, and others [27–29]. There are various solutions for the NLSE, such as general breather (GB), Akhmediev breather (AB), Ma soliton (MS) and rogue wave (RW) solutions. One of the important types of solutions is the Kuznetsov–Ma (KM) soliton, which shows that an unusual pulsating dynamics has attracted particular attention in plasma physics in the context of understanding nonlinear coherent phenomena [30].
Furthermore, the stochastic perturbations that occur in the physical setting, occur from various unknown reasons. These reasons may give rise to some statistical features and significant phenomena in applied science. Thus stochastic differential equations that are more accurate mathematical models of real-world situations are created [31]. Moreover, stochastic nonlinear equations are important in various areas, including nonlinear optics, biology, economy, and plasma physics [32,33].

In this paper, we consider the 2D-SCNLSE, which is given in the following form [34]

\[ i\psi_t + a(\psi_{xx} + \psi_{yy}) + i \left( b_1(\psi\psi^*_x - \psi^*\psi_x) + b_2(\psi\psi^*_y - \psi^*\psi_y) \right) \psi + \sigma \beta(t) = 0, \tag{1} \]

where \( \psi = \psi(x, y, t) \) is a complex function, \( * \) represents the complex conjugate, \( a \) is the second-order dispersion coefficient, \( b_1 \) and \( b_2 \) are the self-steepening coefficients, \( \sigma \) is the noise strength and \( \beta(t) = \frac{d\beta}{dt} \) is the time derivative of the Brownian motion \( \beta(t) \). This noise may be used as an attempt to describe the impact of neglected terms on the modulating of the NLS equation. Stochastic Schrödinger equations have been used in quantum optics to explain the system state conditioned by measurement outcomes. Additionally, the noise term in Equation (1) can describe inhomogeneity in the medium where the wave propagates the source of the noise.

At this point, it is convenient to provide a definition of \( \beta(t) \). Brownian motion (also called one-dimensional Wiener process) is a stochastic process \( \{\beta(t)\}_{t\geq 0} \) with the following properties: (i) \( \beta(0) = 0 \), (ii) \( \beta \) has continuous trajectories, (iii) the process \( \{\beta(t)\}_{t\geq 0} \) has stationary, independent increments, and (iv) for \( s < t \) the stochastic variable \( \beta(s) - \beta(t) \) has the normal distribution \( N(0; t - s) \). The multiplicative noise in Equation (1) describes a process where the phase of the excitation is disturbed. In this paper, we consider the Brownian motion \( \beta(t) \) as a constant in space. The stochastic integral \( \int_0^t \psi(s)d\beta(s) \) is called Itô, if we evaluate this integral at the left end—see [31,35] for more details.

Various methods have been investigated to look for the solutions of the 2D-SCNLSE with \( \sigma = 0 \) (without stochastic term); this includes the extended direct algebraic and extended trial equation method [36], the exp(−\( \varphi \))-expansion method and the modified simple equation method [37], and the trial solution method [34], while Equation (1) with stochastic term is not studied before.

Our aim in this paper is to get the stochastic exact solutions of the 2D-SCNLSE (1) by using three methods—Riccati–Bernoulli sub-ODE, He’s variational and sine-cosine method. We also consider the effect of the stochastic term on the solutions of this equation. This paper is the first to obtain the different kinds of the exact solutions of the 2D-SCNLSE (1) coercive by multiplicative noise. The fundamental advantages for the proposed three methods over the most of other methods is that they give many new exact solutions along with additional free parameters. These methods are straightforward, direct, simple and powerful. Indeed these methods give different types of soliton wave solutions, which describe different phenomena in chiral nature. Since our approach is new, namely studying the stochastic equations in the Itô sense by multiplicative noise, we plan to consider the 2D-SCNLSE (1) with other interesting methods in the future work.

This article is arranged as follows: In Section 2, we obtain the solitary wave solution by applying three different methods and therefore the stochastic exact solutions of the 2D-SCNLSE. In Section 3, we give physical interpretation for the 2D-SCNLSE. In Section 4, we illustrate the influence for multiplicative noise on the solution to the 2D-SCNLSE (1). In Section 5, we give the conclusions of this paper.

2. The Exact Solutions of the 2D-CNLSE

In this section, to get the solitary wave solution of the 2D-SCNLSE (1), we utilize the wave transformation

\[ \psi(x, y, t) = u(\xi)e^{i\theta}, \quad \xi = \rho_1 x + \rho_2 y + \rho_3 t \quad \text{and} \quad \theta = \theta_1 x + \theta_2 y + \theta_3 t + \sigma \beta(t), \tag{2} \]
where $\rho_k, \theta_k$ are nonzero constants for $k = 1, 2, 3,$ $u$ is a real function whereas $\sigma$ is the noise strength. Substituting Equation (2) into Equation (1) and using

$$i \frac{d\psi}{dt} = (i\rho_3 u' - \theta_3 u - \sigma u \beta_1)e^{i\theta},$$
$$\frac{d\psi}{dx} = (\rho_1 u' + i\theta_1 u)e^{i\theta}, \quad \frac{d\psi^*}{dy} = (\rho_2 u' + i\theta_2 u)e^{-i\theta},$$

(3)

to obtain for imaginary part

$$(\rho_3 + 2a\rho_1\theta_1 + 2b\rho_2\theta_2)u',$$

(4)

and for real part

$$a(\rho_1^2 + \rho_2^2)u'' - (2b_1\theta_1 + 2b_2\theta_2)u^3 - (\theta_3 + a\theta_1^2 + a\theta_2^2)u = 0.$$  

(5)

From Equation (4) we obtain the velocity profile of the soliton

$$\rho_3 = -(2a\rho_1\theta_1 + 2a\rho_2\theta_2).$$  

(6)

Dividing Equation (5) by $a(\rho_1^2 + \rho_2^2)$ to get

$$u'' - \Lambda_1\psi^3 - \Lambda_2\psi = 0,$$  

(7)

where

$$\Lambda_1 = \frac{2b_1\theta_1 + 2b_2\theta_2}{a(\rho_1^2 + \rho_2^2)} \quad \text{and} \quad \Lambda_2 = \frac{(\theta_3 + a\theta_1^2 + a\theta_2^2)}{a(\rho_1^2 + \rho_2^2)}.$$  

(8)

In the following subsections we apply three methods—Riccati–Bernoulli sub-ODE method, He’s variational principle and sine–cosine method to obtain the solitary wave solutions of Equation (7). After that we get the solutions of the 2D-SCNLSE (1) with stochastic term.

2.1. Riccati–Bernoulli Sub-ODE Method

Here, we take the following Riccati–Bernoulli equation [2,22]:

$$u' = \gamma_1u^2 + \gamma_2u + \gamma_3,$$  

(9)

where $\gamma_1, \gamma_2, \gamma_3$ are constants.

From Equation (9), we obtain

$$u'' = 2\gamma_1uu' + \gamma_2u',$$  

utilizing Equation (9), gives

$$u'' = 2\gamma_1^2u^3 + 3\gamma_1\gamma_2u^2 + (2\gamma_1\gamma_3 + \gamma_2^2)u + \gamma_2\gamma_3.$$  

(10)

Substituting (10) into (7), we have

$$(2\gamma_1^2 - \Lambda_1)u^3 + 3\gamma_1\gamma_2u^2 + (2\gamma_1\gamma_3 + \gamma_2^2 - \Lambda_2)u + \gamma_2\gamma_3 = 0.$$  

Putting each coefficient of $u^i (i = 0, 1, 2, 3)$ with zero, yields system of algebraic equations. Solving these equations, gives
\[ \gamma_1 = \pm \sqrt{\frac{\Lambda_1}{2}} = \pm \sqrt{\frac{b_1\theta_1 + b_2\theta_2}{a(\rho_1^2 + \rho_2^2)}}, \] (11)
\[ \gamma_2 = 0, \] (12)
and
\[ \gamma_3 = \Lambda_2 \frac{2}{\gamma_1} = \pm \frac{\Lambda_2}{\sqrt{2\Lambda_1}} = \pm \frac{(\theta_3 + a\theta_1^2 + a\theta_2^2)}{2\sqrt{b_1\theta_1 + b_2\theta_2}}, \] (13)
where we used Equation (8).

Now, let us deduce the stochastic solution of the Equation (1). There are many cases depending on
\[ \frac{\gamma_3}{\gamma_1} > 0, \] (14)
or
\[ \frac{\gamma_3}{\gamma_1} < 0, \] (15)

First case: If \( \frac{\gamma_3}{\gamma_1} > 0 \), then the solution of Equation (9) is
\[ u(\xi) = \sqrt{\frac{\gamma_3}{\gamma_1}} \tan \left( \sqrt{\frac{\gamma_3}{\gamma_1}} (\gamma_1 \xi + C) \right), \] (16)

Second case: If \( \frac{\gamma_3}{\gamma_1} < 0 \) and \( |\varphi| < \sqrt{-\frac{\gamma_1}{\gamma_3}} \), then the solution of Equation (9) is
\[ u(\xi) = \sqrt{-\frac{\gamma_3}{\gamma_1}} \tanh \left( \sqrt{-\frac{\gamma_3}{\gamma_1}} (\gamma_1 \xi + C) \right), \] (17)

Third case: If \( \frac{\gamma_3}{\gamma_1} < 0 \) and \( \varphi^2 > \frac{\gamma_3}{\gamma_1} \), then the solution of the Equation (9) is
\[ u(\xi) = \sqrt{-\frac{\gamma_3}{\gamma_1}} \coth \left( \sqrt{-\frac{\gamma_3}{\gamma_1}} (\gamma_1 \xi + C) \right). \] (18)
In this case, we can use Equation (2) with Equation (20) to get the stochastic solution of the Equation (1) as

\[
\psi(x, y, t) = e^{i[\theta_1 x + \theta_2 y + \beta t + \sigma \beta(t)]} \sqrt{-\gamma_3 / \gamma_1} \coth \left( \frac{\gamma_3}{\gamma_1} (-\gamma_1 (\rho_1 x + \rho_2 y - 2a(\rho_1 \theta_1 + \rho_2 \theta_2) t) + C) \right),
\]

where \(\gamma_1\) and \(\gamma_3\) are defined in Equations (11) and (13).

2.2. He’s Variational Principle Method

Based on the He’s variational principle [20,38,39], one establishes the following trial-functional:

\[
J(u) = \int_0^\infty \left\{ \frac{1}{2} (u')^2 + \frac{1}{4} \Lambda_1 u^4 + \frac{1}{2} \Lambda_2 u^2 \right\} d\xi. \tag{22}
\]

According to Ref. [40], the solution for constant \(R\) of Equation (7) is

\[
u(\xi) = R \sec h(\xi), \tag{23}
\]

Superseding Equation (23) into Equation (22) gives

\[
J = \int_0^\infty \left[ \frac{R^2}{2} \sec h^2(\xi) \tanh^2(\xi) + \frac{R^4}{4} \Lambda_1 \sec h^4(\xi) + \frac{R^2}{2} \Lambda_2 \sec h^2(\xi) \right] d\xi
= \frac{R^2}{6} + \frac{R^4}{6} \Lambda_1 + \frac{R^2}{6} \Lambda_2.
\]

Making \(J\) stationary with \(R\) results in

\[
\frac{\partial J}{\partial R} = \frac{1}{3} (1 + \Lambda_2) R + \frac{\Lambda_1}{3} R^3 = 0.
\]

From this equation, we have

\[
R = \sqrt{-\frac{(1 + \Lambda_2)}{\Lambda_1}}.
\]

Hence

\[
u(\xi) = \sqrt{-\frac{(1 + \Lambda_2)}{\Lambda_1}} \sec h(\xi), \tag{24}
\]

where \(\Lambda_1\) and \(\Lambda_2\) are defined in Equation (8).

Now, we can use Equation (2) with Equation (24) to obtain the stochastic solution of the 2D-CNLSE (1) as

\[
\psi(x, y, t) = u(\xi) e^{i[\theta_1 x + \theta_2 y + \beta t + \sigma \beta(t)]} \sqrt{-\frac{(1 + \Lambda_2)}{\Lambda_1}} \sec h(\rho_1 x + \rho_2 y - 2a(\rho_1 \theta_1 + \rho_2 \theta_2) t). \tag{25}
\]

Analogously, we can take

\[
u(\xi) = R \sec h^2(\xi), \quad \nu(\xi) = R \csc h(\xi) \quad \text{and} \quad \nu(\xi) = R \csc h^2(\xi),
\]

to get different forms of solitary wave solutions.
2.3. Sine–Cosine Method

We apply the sine–cosine method to solve Equation (7) and consequently the stochastic solution of the 2D-CNLS (1). According to [12,13], let the solution \( u \) of Equation (7) take the form

\[
 u(\eta) = A \Upsilon^m, \tag{26}
\]

where

\[
 \Upsilon = \sin(B\zeta) \quad \text{or} \quad \Upsilon = \cos(B\zeta). \tag{27}
\]

Substituting Equation (26) into Equation (7) we have

\[
 -AB^2[-m^2\Upsilon^m + m(m-1)\Upsilon^{m-2}] - \Lambda_1 A^3 \Upsilon^3 m - \Lambda_2 A \Upsilon^m = 0,
\]

rewriting the above equation

\[
 (\Lambda_2 A - AB^2 m^2) \Upsilon^m + m(m-1)AB^2 \Upsilon^{m-2} + \Lambda_1 A^3 \Upsilon^3 m = 0. \tag{28}
\]

Balancing the term of \( \Upsilon \) in Equation (28), we get

\[
 m - 2 = 3m \implies m = -1. \tag{29}
\]

Substituting Equation (29) into Equation (28)

\[
 (\Lambda_2 A - AB^2)^{-1} + (\Lambda_1 A^3 + 2AB^2)^{-3} = 0. \tag{30}
\]

Equating each coefficient of \( \Upsilon^{-1} \) and \( \Upsilon^{-3} \) to zero, we obtain

\[
 \Lambda_2 A - AB^2 = 0, \tag{31}
\]

and

\[
 \Lambda_1 A^3 + 2AB^2 = 0. \tag{32}
\]

By solving these equations we get

\[
 B = \sqrt{\Lambda_2} = \sqrt{\frac{(\theta_3 + a\theta_1^2 + a\theta_2^2)}{a(\rho_1^2 + \rho_2^2)}} \quad \text{and} \quad A = \sqrt{-\frac{2\Lambda_2}{\Lambda_1}} = \sqrt{-\frac{(\theta_3 + a\theta_1^2 + a\theta_2^2)}{b_1\theta_1 + b_2\theta_2}}. \tag{33}
\]

Then the solitary wave solution of Equation (7) takes the form

\[
 u(\xi) = A \sec(B\xi) \quad \text{or} \quad u(\xi) = A \csc(B\xi), \tag{34}
\]

therefore, we can use Equation (2) with Equation (34) to get the stochastic exact solution of the 2D-CNLS (1) as

\[
 \psi(x, y, t) = A \sec[B(\rho_1 x + \rho_2 y - 2a(\rho_1^2 + \rho_2^2)t)] e^{i[\theta_1 x + \theta_2 y + \theta_3 t + \sigma\beta(t)]}, \tag{35}
\]

or

\[
 \psi(x, y, t) = A \csc[B(\rho_1 x + \rho_2 y - 2a(\rho_1^2 + \rho_2^2)t)] e^{i[\theta_1 x + \theta_2 y + \theta_3 t + \sigma\beta(t)]}, \tag{36}
\]

where \( A \) and \( B \) are defined in (33).
3. Physical Interpretation

The 2D-CNLS equation has been constructed by a 1-D reduction of the structure that defines the fractional quantum Hall effect. The exact solutions of the 2D-CNLS (1) were obtained in the explicit form with the aid of the Riccati–Bernoulli sub-ODE, He’s variational approach and sine–cosine methods. Distinct types of traveling wave solutions are revealed—for example, solitary wave, dark solitons, bright solitons and periodic solitary wave solutions. The behavior of solutions for the Equation (1) being solitons, dissipative or periodic and so on, is an indication for the values of the physical parameters in the dispersion and nonlinear coefficients. Indeed the NLSE plays a vital role to describe the full spatiotemporal optical solitons or light bullets in nonlinear optics. Our study shows that the proposed three methods are reliable in handling NPDEs to establish a variety of exact solutions.

Dark and bright solitons propagate in nonlinear dispersive media. Dark soliton depicts the solitary waves with lower intensity than the background while bright soliton depicts the solitary waves whose peak intensity is larger than the background [41]. The all gained solutions in this article depict the wave profiles in various applications in applied science. Specifically, the acquired solutions may be interpreted the spatio-temporal solutions, nuclear physics, telecommunications experiments, space observations, space observations, capillary profiles, chaotic pulses laser and transistor [42–46]. Indeed, the gained solutions are of great importance in the development of quantum mechanics, namely in quantum hall effect, the entire computer industry and nuclear medicine.

The understanding of the effect of a noise on the propagation of waves is a very vital problem. Even the propagation is often depicted by deterministic models, in many circumstances randomness should be considered. It can drastically change the qualitative behavior and result in new properties. Stochastic Schrodinger equations have been utilized in quantum optics to explain the system state conditioned by measurement outcomes. Additionally, the noise term in Equation (1) can depict inhomogeneity in the medium where the wave propagates or the source of the noise. In sequel, we are particularly interested in the effect of a noise acting as a potential on this behavior.

4. The Effect of Multiplicative Noise on the Solutions of the 2D-CNLS

In this section, we study the effect of multiplicative noise on the solution of the 2D-CNLS (1). The behavior of the solutions for the 2D-CNLS (1) being solitons, dissipative or periodic and so on, is an indication for the values of the physical parameters in the dispersion and nonlinear coefficients. We introduce some 2D, 3D and the contour graphs for different values of noise strength. For our purpose, we use Matlab package in the following sense. Fix the parameters $a = 0.7, b_1 = 1.4, \theta_1 = 0.6, b_2 = 1.9, \theta_2 = 0.8, \theta_3 = -2.1, \rho_1 = 1, \rho_2 = 1.6, C = 1$. We introduce a variety of simulations for various value of $\sigma$ (noise intensity).

We consider the solution (19) in order to illustrate our purpose in a completely unified way. For the noise intensity $\sigma = 0$, the profile wave for the 2D-CNLS (1) fluctuates and its profile is depicted in Figure 1. When the noise intensity $\sigma$ increases, the profile wave is destroyed, as shown in Figures 2–4. Figure 5 illustrates the 2D graph corresponding to the solution (19) for $\sigma = 0; 1; 3; 5$. The figures highlight the physical nature of the solution by the careful choice of arbitrary parameters satisfying the constraints.
Figure 1. The 3D graph and the contour of $\psi$ in (19) and $\sigma = 0$.

Figure 2. The 3D graph and the contour of $\psi$ in (19) and $\sigma = 1$. 
Figure 3. The 3D graph and the contour of $\psi$ in (19) and $\sigma = 3$.

Figure 4. The 3D graph and the contour for $\psi$ in (19) and $\sigma = 5$. 
5. Conclusions

In this study, the powerful Riccati–Bernoulli sub-ODE, He’s variational principle and sine-cosine methods are utilized in searching the presence of soliton solutions in quantum hall effect via the \((2 + 1)\)-dimensional stochastic Chiral nonlinear Schrödinger equation. We successfully obtained some dark and bright soliton solutions to this equation. The obtained solutions are essential in interpreting some complicated physical phenomena. Moreover, we considered the influence of multiplicative noise on the solutions for the 2D-CNLE. Some graphic representations were introduced with the aid of Matlab software 18 to demonstrate the behavior of these solutions. We observed that three proposed methods are simple and powerful mathematical tools that give vital results when applied to various types of nonlinear models.
