ABSTRACT: Parkinson’s disease (PD) is an age-related neurodegenerative disorder affecting many people in the world. Several gene mutations have shed light on the mechanisms of pathogenesis of PD. The parkinsonian syndrome is associated with several other degenerative and non-degenerative diseases. Genes linked to PD are synuclein, Parkinson’s disease autosomal recessive, juvenile 2, Parkinson's disease autosomal recessive, early onset 7, PTEN-induced putative kinase 1 and leucine-rich repeat kinase 2. The initial symptomatic therapy and adjuvant therapy in later PD are also discussed.

KEYWORDS: Parkinson's Disease, parkinsonian syndrome, Degenerative disorders, inhibitors

INTRODUCTION: Parkinson’s disease (PD) akinetic-rigid syndrome refers to group of conditions which are termed to be motor system disorders, which are the result of loss of dopamine-producing brain cells.¹ Parkinson’s disease (PD) is the second most common neurodegenerative disorder after Alzheimer’s disease, affecting around 100,000 people in the UK. Parkinson’s disease (PD) is an age-related neurodegenerative disorder.² With the increase in ageing population, management of PD is likely to prove an increasingly important and challenging aspect of medical practice for neurologists and general physicians. Advancements of last decade depict several gene mutations which shed light on the mechanisms of pathogenesis in sporadic cases of PD.³

About 30% of patients with pathologically proven PD have no tremor during life. The National Institute for Health and Clinical Excellence (NICE) recommends that a clinician who suspects a patient has PD should refer them quickly to a specialist (a neurologist or geriatrician) and that the patient should be seen within 6 weeks of referral. The current theory (so-called Braak's hypothesis) is that the earliest signs of Parkinson's are found in the enteric nervous system, the medulla and in particular, the olfactory bulb, which controls your sense of smell. Under this theory, Parkinson's only progresses to the substantia nigra and cortex over the years. This theory is increasingly borne out by evidence that non-motor symptoms, such as a loss of sense of smell, hyposmia, sleep disorders and constipation may precede the motor features of the disease by several years. For this reason, researchers are increasingly focused on these “non-motor” symptoms to both detect PD as early as possible and to look for ways to stop its progression.⁴

Historical background: Descriptions of people with Parkinsonism date back to ancient Egypt. Auguste François Chomel, a French pathologist, John Hunter, a Scottish surgeon, Hieronymus David Gaubius, a German physician and chemist, and Franciscus Sylvius, a Dutch chemist, physiologist and anatomist, all described Parkinson’s-type signs and symptoms during the 17th and 18th centuries.

PD is the second most prevalent neurodegenerative disease, and levodopa is considered the most effective drug for managing PD. Rotigotine is a non-ergot dopamine agonist that is suitable for transdermal delivery via skin patches,⁵ once administered daily, it provides stable plasma
concentrations over 24 hours. Non-oral routes of rotigotine delivery are particularly useful in patients scheduled for surgery or in those with dysphagia.\textsuperscript{6}

**Symptoms:** PD symptoms vary from person to person with unnoticed early signs. Symptoms often start in one side of the body and extending to both sides. Mostly they include: Tremor, slowed movement, rigid muscles, impaired posture and balance, loss of automatic movements, speech changes and writing chances.

Complications include: difficulty in thinking, depression and emotional changes, swallowing problems, sleep problems and disorders, bladder problems, constipation, blood pressure changes, smell dysfunction, fatigue, pain, sexual dysfunction.

**Diagnosis:** Accurate or no ‘one way’ to diagnose underpins the management of PD various symptoms and diagnostic tests are used in combination to diagnose PD. Whilst Parkinson’s disease is the commonest cause of a parkinsonian syndrome, there are several other degenerative and non-degenerative diseases (Table 1) that can mimic it. It is important to distinguish these mimics because many do not respond to the treatment used for PD and they have a different prognosis from PD.\textsuperscript{6}

| Degenerative disorders                  | Non-degenerative disorders                  |
|-----------------------------------------|---------------------------------------------|
| Multiple system atrophy                | essential tremor                            |
| Progressive supranuclear palsy          | Dystonic tremor                             |
| Corticobasal degeneration               | Cerebrovascular disease                     |
| Dementia with Lewy bodies               | Drug-induced parkinsonism                   |
| Alzheimer\'s disease                    |                                             |

**Table 1: Common mimics of Parkinson\'s disease**

Genes linked to Parkinson\'s disease:
1. SNCA (synuclein, alpha non A4 component of amyloid precursor)
2. PARK2 (Parkinson\'s disease autosomal recessive, juvenile 2)
3. PARK7 (Parkinson\'s disease autosomal recessive, early onset 7)
4. PINK1 (PTEN-induced putative kinase 1)
5. LRRK2 (leucine-rich repeat kinase 2)

In its early stages, Parkinson\'s disease can resemble a number of other conditions with Parkinson-like symptoms known as Parkinsonism. These conditions include multiple system atrophy, progressive supranuclear palsy, corticobasal degeneration, Lewy body dementia, stroke, encephalitis (inflammation of the brain), and head trauma. Using transgenic mice and fly models, Kurosiinski et al\textsuperscript{7} found mutations in the gene SYN (A30P and A53T) can be attributed to the onset of PD that cause internal cellular α-synuclein to aggregate and deposit to form Lewy bodies, which are hallmarks of PD. Abramov et al.\textsuperscript{8} suggested that the manifestation of PD can be attributed to different genes in a 5 human disease models, where mutation in PTEN induced kinase-1 gene producing mitochondrial PINK1 protein was observed. Another aspect of importance in PD is due to unstable free radicals which are a byproduct of oxidative stress contributing to nerve cell death.\textsuperscript{9} Katzenschlager et al reported that the seed powder of the leguminous plant, Mucuna pruriens has long been used in traditional Ayurvedic Indian medicine for diseases including parkinsonism.\textsuperscript{10}

The Management of Early Parkinson\'s disease\textsuperscript{11} includes levodopa, dopamine agonists or monoamine oxidase type B (MAOB) inhibitors (Table 2).
First choice option | Degree of symptom control | Risk of side effects  
|---------------------|--------------------------|----------------------
| Levodopa            | Yes                      | Good                 | Increased | Increased |
| Dopamine agonists   | Yes                      | Moderate             | Reduced   | Increased |
| Monoamine-oxidase-B inhibitors | Yes | Limited               | Reduced   | Increased |
| Anticholinergics    | No                       | Lack of evidence     | Lack of evidence | Lack of evidence |
| Beta-blockers       | No                       | Lack of evidence     | Lack of evidence | Lack of evidence |
| Amantadine          | No                       | Lack of evidence     | Lack of evidence | Lack of evidence |

| First choice option | Degree of symptom control | Risk of side effects  
|---------------------|--------------------------|----------------------
| Dopamine agonists   | Yes                      | Moderate             | Reduced   | Increased |
| Catechol-O-methyltransferase inhibitors | Yes | Moderate               | Reduced   | Increased |
| Monoamine-oxidase-B inhibitors | Yes | Moderate               | Reduced   | Increased |
| Amantadine          | No                       | Not significant      | Reduced   | Increased |
| Beta-blockers       | No                       | Lack of evidence     | Lack of evidence | Lack of evidence |
| Apomorphine         | No                       | Limited              | Reduced   | Increased |

Table 2: Options for initial symptomatic therapy for Parkinson’s disease

The Management of Early Parkinson’s disease includes adjuvant therapy to levodopa with a dopamine agonist, a MAOB inhibitor or a catechol-O-methyl transferase (COMT) inhibitor (Table 3).

Though the exact cause of PD remains unknown, there are prevailing hypotheses in literature which show that there is a distinct correlation between environmental toxin exposure and the onset of PD. Mutations in SYN and PINK loci have led to PD.

Few treatments have been proven to reduce the progression of Parkinson disease. However, it should be understood that medications are usually effective in controlling the symptoms of PD. Either levodopa or a dopamine agonist can be used initially for patients who require treatment for symptoms of Parkinson disease. Levodopa is the drug of choice if symptoms of Parkinson disease are
serious. Other drugs such as Selegiline (Symmetrel®) and Rasagiline (Azilect®) are MAO B inhibitors that may help to relieve mild symptoms in some people with early Parkinson disease. Anticholinergic drugs are usually reserved for younger patients in whom tremor is the predominant problem.
