A RESULT ON THE EQUATION \( x^p + y^p = z^r \) USING FREY ABELIAN VARIETIES

NICOLAS BILLEREY, IMIN CHEN, LUIS DIEULEFAIT, AND NUNO FREITAS

Abstract. We prove a diophantine result on generalized Fermat equations of the form \( x^p + y^p = z^r \) which for the first time requires the use of Frey abelian varieties of dimension \( \geq 2 \) in Darmon’s program. For that, we provide an irreducibility criterion for the mod \( p \) representations attached to certain abelian varieties of GL\(_2\)-type over totally real fields.

1. Introduction

Darmon [2] has initiated a remarkable program to study the generalized Fermat equation

\[
(1.1) \quad x^p + y^q = z^r, \quad 1/p + 1/q + 1/r < 1, \quad x, y, z \in \mathbb{Z}, \quad xyz \neq 0, \quad \gcd(x, y, z) = 1,
\]

where the exponents \( p, q, r \geq 2 \) are prime numbers. He divides the analysis of this equation into the three one-parameter families \((r, r, p)\), \((p, p, r)\) and \((r, q, p)\) where in each case the parameter \( p \) is allowed to vary and the other exponents are fixed. A notable feature of his program is that it uses higher dimensional abelian varieties and their (still mostly conjectural) modularity instead of just elliptic curves. However, very little is understood about the relevant abelian varieties and Darmon’s program has not yet produced any diophantine result, apart from a few cases where the abelian varieties involved are of dimension one, i.e. elliptic curves.

Darmon’s program follows the strategy of the ‘modular method’: the Frey abelian variety \( A(x, y, z) \) attached to a non-trivial (i.e. \( xyz \neq 0 \)) putative solution \((x, y, z)\) of (1.1) can be distinguished from the abelian varieties attached to the known trivial solutions (i.e. \( xyz = 0 \)) through their galois representations. Indeed, the \( p \)-torsion representation attached to \( A(x, y, z) \) should be large in general, while if \((x, y, z)\) is a trivial solution then this image is usually reducible or contained in the normalizer of a Cartan subgroup. Modularity of the abelian varieties \( A(x, y, z) \) and level lowering results imply a congruence mod \( p \) between eigenforms, which bounds \( p \) under the set up described above. Another interesting feature of Darmon’s program is the use of classical cyclotomic criteria to eliminate the possibility of a congruence to an \( r \)-Eisenstein \( \mathbb{Q} \)-form at the lower levels [2, Proposition 3.20].

The objective of this work is twofold. We first develop an irreducibility criterion for the \( p \)-torsion representations attached to certain families of abelian varieties. Secondly, by following the idea in the previous paragraph and results from loc. cit., we will show how the

criterion can be used to unconditionally establish a diophantine statement via Darmon’s program that for the first time requires Frey abelian varieties of dimension $\geq 2$.

We recall that an odd prime number $r$ is called regular if it does not divide the class number of the cyclotomic field $\mathbb{Q}(\zeta_r)$. It is an open conjecture due to Siegel that there are infinitely many regular primes. We will prove the following theorem.

**Theorem 1.** Let $r \geq 5$ be a regular prime. There exists a constant $C(r)$ such that for every prime number $p > C(r)$ the equation

$$x^p + y^p = z^r$$

has no non-trivial (i.e. $abc \neq 0$) proper (i.e. $\gcd(a, b, c) = 1$) solutions $(a, b, c) \in \mathbb{Z}^3$ satisfying $r \mid ab$ and $2 \nmid ab$.

**Acknowledgements.** Dieulefait would like to thank Eknath Ghate for several useful conversations during an early phase of this project.

2. **An irreducibility criterion**

The following terminology has been introduced by Ribet.

**Definition 2.1.** An abelian variety $A$ over a number field $K$ is said to be of GL$_2$-type if its endomorphism algebra $\text{End}_K(A) \otimes \mathbb{Q} = F$ is a number field satisfying $[F : \mathbb{Q}] = \dim A$.

Let $A/K$ be an abelian variety of GL$_2$-type. Set $F = \text{End}_K(A) \otimes \mathbb{Q}$ and let $p$ be a prime number. Denote by $T_p(A)$ the Tate module of $A$ and write $V_p(A) = T_p(A) \otimes \mathbb{Q}_p$. Then, for each prime ideal $\mathfrak{p}$ of $F$ over $p$, the absolute Galois group $G_K$ of $K$ acts $F_\mathfrak{p}$-linearly on $V_p(A) = V_p(A) \otimes_{F_\mathfrak{p}} F_\mathfrak{p}$ where $F_\mathfrak{p}$ denotes the completion of $F$ at $\mathfrak{p}$ and $F_\mathfrak{p} = F \otimes \mathbb{Q}_p = \prod_{\mathfrak{p} | p} F_\mathfrak{p}$. This gives rise to a strictly compatible system of 2-dimensional $p$-adic Galois representations

$$\bar{\rho}_{A,p} : G_K \longrightarrow \text{GL}_2(F_\mathfrak{p}).$$

The representation $\bar{\rho}_{A,p}$ can be conjugated to take values in $\text{GL}_2(\mathcal{O}_p)$ where $\mathcal{O}_p$ stands for the ring of integers in $F_\mathfrak{p}$. By reduction modulo the maximal ideal, we then get a representation

$$\rho_{A,p} : G_K \longrightarrow \text{GL}_2(\mathbb{F}_p),$$

with values in the residue field $\mathbb{F}_p$ of $F_\mathfrak{p}$ which is unique up to semi-simplification and isomorphism.

The aim of this section is to provide a uniform bound on the residual characteristic of prime ideals $\mathfrak{p}$ for which the corresponding representations $\rho_{A,p}$ is reducible when $A$ runs through certain families of abelian varieties of GL$_2$-type. For elliptic curves over totally real fields, such irreducibility criteria were previously known and different variants (for various families of curves) can be found in the work of Serre [11], Kraus [7, 8], Billerey [1], David [3], Dieulefait-Freitas [4] and Freitas-Siksek [5].

Recently, Larson and Vaintrob [9] have proven general results which classify the so-called associated mod $p$ characters of abelian varieties $A$ over a number field $K$ for $p$ sufficiently large. Their results have consequences to proving irreducibility criteria for the representations $\rho_{A,p}$ which we discuss here with a view towards applications to Frey abelian varieties.

For that purpose, we introduce some useful definitions.
Definition 2.2. Let $A/K$ be an abelian variety with potentially good reduction at a prime $q$ of a number field $K$. We say that $A$ has residual degree $f$ at $q$ if $f$ is minimal among the degree of the residual extensions corresponding to all extensions $L/K_q$ such that $A/L$ has good reduction.

The following definition is motivated by [9, Lemma 4.6].

Definition 2.3. We say that an abelian variety $A/K$ has inertial exponent $c \in \mathbb{N}$ if for every finite prime $v$ of the number field $K$, there exists a finite galois extension $M/K$ such that $A/M$ is semistable at all primes of $M$ lying over $v$, and the exponent of the inertia subgroup at $v$ of $\text{Gal}(M/K)$ divides $c$.

We write $\mathbb{Z}$ for the ring of integers of $\mathbb{Q}$. Given an ideal $q$ of the ring of integers of a number field $K$, we write $N(q)$ for its norm.

Theorem 2. Let $K$ be a totally real number field and fix a prime $q$ of $K$. Let $c, f \geq 1$ be integers with $c$ even. Consider a finite set $S_f(q)$ of elements of the form $\alpha_1 + \alpha_2$ where $\alpha_i \in \mathbb{Z}$ are of complex absolute value $N(q)^{f/2}$ and $\alpha_1 \alpha_2 = N(q)^f$.

Then there exists a constant $c_1 = c_1(K,c,f,S_f(q))$ such that the following holds. Suppose that $p > c_1$ and $A/K$ is an abelian variety satisfying

(i) $A$ is semistable at the primes of $K$ above $p$,
(ii) $A$ is of $GL_2$-type with multiplications by some totally real field $F$,
(iii) all endomorphisms of $A$ are defined over $K$, that is $\text{End}_K(A) = \text{End}_{\mathbb{Q}}(A)$,
(iv) $A$ over $K$ has inertial exponent $c$,
(v) $A$ has potentially good reduction at $q$ with residual degree $f$,
(vi) the trace of $\text{Frob}_q^f$ acting on $V_p(A)$ lies in $S_f(q)$, where $p$ is a prime of $F$ above $p$.

Then the representation $\rho_{A,p}$ is irreducible.

Remark 2.4. Let $L/K_q$ be an extension with residual degree $f$ such that $A$ over $L$ has good reduction. Let $q'$ be the maximal ideal of $L$. Then $\text{Frob}_{q'} = \text{Frob}_q^f$ and hence the characteristic polynomial of $\rho_{A,p}(\text{Frob}_q^f)$ is well-defined.

Remark 2.5. In the application to the generalized Fermat equation, we will take $S_f(q)$ to be the set of traces of $\text{Frob}_q^f$ on $V_p(A(x,y,z))$, where $A(x,y,z)$ is a Frey abelian variety attached to a solution $(x,y,z)$ of $x^p + y^p = z^r$. To compute this set, we let $(x,y,z)$ run through all triples in $(\mathbb{Z}/q\mathbb{Z})^3$ such that $x^p + y^p \equiv z^r \pmod{q}$ and $A(x,y,z)$ has potentially good reduction at $q$ lying over $q$, for some choice of $q$, $c$, and $f$.

Proof of Theorem 2. Let $A$ be an abelian variety satisfying conditions (i)-(v) in the statement. Suppose that $\rho_{A,p}$ is reducible. Let $\psi_i : G_K \to \mathbb{F}_p^*$, for $i = 1, 2$, denote the two diagonal characters of $\rho_{A,p}$. Then each $\psi_i$ is an associated mod $p$ character of $A$ of degree 1 in the sense of [9, page 518]. Since $A$ has inertial exponent $c$, then $\psi_i^c$ is unramified at all primes $v \nmid p$ of $K$ by [6, Proposition 3.5 (iv)]. Moreover, since by assumption (iv) $c$ is even, $\psi_i^c$ is unramified at infinity.

We note that in loc. cit. a quantity $c = c(q)$ is used, however, the proofs of the results there are still valid as long as the $A$ in question has inertial exponent $c$ which is even.
We identify $\psi_i$ with a character of the ideles using the reciprocity map of global class field theory. Let $\theta^S$ be defined as in [9, Definition 2.6] (with $L = \overline{\mathbb{Q}}$ in their notation), where $S \in \mathbb{Z}[\Gamma_K]$ and $\Gamma_K$ is the set of embeddings of $K$ into $\overline{\mathbb{Q}}$.

By [9, Lemma 5.4] and the semistability assumption (i), there exists $S_i \in \mathbb{Z}[\Gamma_K]$ such that $\psi_i(x_p)^c \equiv \theta^{S_i}(x)^c \pmod{p}$ for all $x \in K^\times$ relatively prime to $p$, where $x_p$ is the prime to $p$-part of $x$ regarded as an idèle of $K$.

We note that the invocation of [9, Lemma 5.4] requires $p \nmid \Delta_K$, where $\Delta_K$ is the absolute discriminant of $K$, because the proof of this lemma uses [9, Lemma 4.10]. However, the condition $p \nmid c$ is not necessary as we assume semi-stability at $p$ by (i), and hence there is no need to use [9, Lemma 4.8].

Let $B_{\text{char}}(K,c)$ be as given in [9, §7.2, p. 548]. For $p \nmid B_{\text{char}}(K,c)$, $\theta^{S_i}$ is balanced by [9, Lemma 2.15, Lemma 5.6 and §7.2]. As $K$ is totally real, a balanced character for $K$ means being a power of the norm character [9, Definition 2.13]. Thus, $\theta^{S_i}$ is a non-negative power of the norm character.

From (ii) $F$ is totally real, and from (iii) $A$ has all of its endomorphisms defined over $K$. Hence [10, Lemma 4.5.1] says that we have

\begin{equation}
\det \rho_{A,p} = \psi_1 \psi_2 = \text{cyc}_p,
\end{equation}

where $\text{cyc}_p$ denotes the mod $p$ cyclotomic character. Thus, $\theta^{S_i}$ is either trivial or the norm character and $\theta^{S_1} \theta^{S_2}$ is the norm character. Hence, by switching $\psi_1$ for $\psi_2$ if necessary, we may assume $\psi_1^c$ is unramified at all primes of $K$.

Let $\iota : \mathbb{F}_p^\times \to \mathbb{C}^\times$ be an injective homomorphism. Then $\iota \circ \psi_1$ is unramified at a prime $v$ of $K$ if and only if $\psi_1$ is unramified at $v$. The group of continuous characters of $G_K$ with values in $\mathbb{C}^\times$ which are unramified at all primes of $K$ are dual to the class group of $K$. Hence, we have that $(\iota \circ \psi_1)^{h'_{\text{K}}} = 1$ where $h'_{\text{K}}$ is the exponent of the class group of $K$. Thus, $\psi_1^{ch'_{\text{K}}} = 1$.

By (v), (vi), and Remark 2.4, we obtain that

$$p \mid \prod_{a \in S_i(q)} \text{Res}(X^{ch'_{\text{K}}} - 1, X^2 - aX + N(q)^f),$$

where $\text{Res}$ denotes the resultant. Therefore, letting $c_1$ denote a constant larger than any prime dividing $B_{\text{char}}(K,c)$, $\Delta_K$, and the above resultant, gives the desired bound. \(\square\)

**Corollary 1.** Let $K$ be a totally real field, $q$ a prime of $K$ and $g$ a positive integer. There is a constant $C(K,g,q)$ such that the following holds: Suppose $p > C(K,g,q)$ is a prime. Then for all $g$-dimensional abelian varieties $A/K$ satisfying conditions (i)–(iii) in Theorem 2 the representation $\rho_{A,p}$ is irreducible.

**Proof.** Since $A$ achieves semi-stable reduction over $K(A[12])$ by [6, Proposition 4.7], and the degree of the galois extension $K(A[12])/K$ is bounded in terms of $g$, this bounds the possible residual degrees of $A$ at $q$ and inertial exponents of $A$ in terms of $g$.

Let $c_{K,g}$ be the product of all the possible inertial exponents from the above paragraph.

If $A$ has residual degree $f$ at the prime $q$ of $K$, then the characteristic polynomial of $\text{Frob}_q^f$ on $T_q(A)$ divides the characteristic polynomial of $\text{Frob}_q^f$ on $T_q(A)$. If the dimension of $A$ is fixed, then by [9, Lemma 7.6] there are only finitely many possibilities for the latter. Hence,
for each possible $f$ from the first paragraph, take $S_f(q)$ to be the set of traces of the finitely many possibilities for the characteristic polynomial of $\text{Frob}_q^f$ on $T_p(A)$.

For each $f$ apply Theorem 2 with $S_f(q)$ and $c = c_{K,g}$ to get a bound $c_f = c(K, c_{K,g}, f, S_f(q))$. The corollary follows by letting $C(K, g, q)$ be the maximum of the $c_f$.

\[\square\]

Remark 2.7. There is an alternate method to deduce irreducibility which follows more directly from [9, Corollary 5.19]. We instead picked the proof above for two reasons. On the one hand, it is more natural as an extension of the proofs known for the case of elliptic curves and, on the other hand, since it uses properties that are normally satisfied by Frey abelian varieties, it should be better suited to giving simpler bounds in concrete diophantine applications.

3. Application to $x^p + y^p = z^r$

In this section we use the irreducibility criterion from the previous section to establish an unconditional diophantine statement as an application of Darmon’s program [2] which requires Frey abelian varieties of dimension $\geq 2$.

For an odd prime $r$, let $\zeta_r$ be a primitive $r$-th root of unity and denote by $K$ the maximal totally real subfield of $\mathbb{Q}(\zeta_r)$. Let $(a, b, c) \in \mathbb{Z}^3$ be a non-trivial proper solution of (1.2). Put $t = a^p/c^r$ and consider the abelian variety $J_r^+(t)$ defined in Section 1.3 of [2]. According to Eq. (5) in loc. cit. one has

$$\text{End}_{\mathbb{Q}}(J_r^+(t)) = \mathcal{O}_K.$$ 

In particular, $J_r^+(t)$ becomes of $\text{GL}_2$-type over $K$ with real multiplication by $K$ (see also [12]). Let $J_r^+(a, b, c)$ be the $\mathbb{Q}$-model of $J_r^+(a^p/c^r)$ defined in [2, p.18].

The following two results follow from (the proof of) Proposition 1.15, Theorem 3.22 and Definition 3.6 of loc. cit.

Lemma 1. Let $(a, b, c) \in \mathbb{Z}^3$ be a non-trivial proper solution to $x^p + y^p = z^r$. Suppose $r \mid ab$. Then the abelian variety $J_r^+(a, b, c)/K$ is semistable. Moreover, if $2 \nmid ab$ it has good reduction at all primes above 2.

Theorem 3. Let $r$ be a regular prime. Then there exists a constant $c_2(r)$ such that, for all $p > c_2(r)$, and non-trivial proper solutions $(a, b, c) \in \mathbb{Z}^3$ to (1.2) with $r \mid ab$, the mod $p$ representation $\rho_{r,p}^+$ associated to $J_r^+(a, b, c)$ is reducible.

As a consequence of these results and our irreducibility criterion in Theorem 2 we can now prove our main diophantine application.

Proof of Theorem 1. Let $(a, b, c) \in \mathbb{Z}^3$ be a non-trivial proper solution to $x^p + y^p = z^r$ satisfying $r \mid ab$ and $2 \nmid ab$. Write $J = J_r^+(a, b, c)/K$. From Lemma 1, we have that $J$ is semistable with good reduction at all $q \mid 2$. In particular, for $J$ we have even inertial exponent $c = 2$ and residual degree $f = 1$ at all $q \mid 2$. Let $q \mid 2$ in $K$. Recalling Remark 2.5, we take $S_f(q)$ to be the singleton set consisting of the trace of $\text{Frob}_q$ on the $p$-torsion of $J = J_r^+(1, -1, 0)$. 

From Theorem 2 we obtain a constant $c_1(r)$ such that if $p > c_1(r)$ and $p | p$ in $K$ then the mod $p$ representation $\rho_{J,p}$ is irreducible.

From Theorem 3 we obtain a constant $c_2(r)$ such that if $p > c_2(r)$ and $p | p$ in $K$ then $\rho_{J,p}$ is reducible.

Letting $C(r)$ be the maximum of $c_1(r)$ and $c_2(r)$, we obtain a contradiction for all exponents $p > C(r)$. □
