NEW PROPERTIES ON NORMALIZED NULL HYPERSURFACES.

CYRIAQUE ATINDOGBE, MANUEL GUTIÉRREZ, AND RAYMOND HOUNNONKPE

Abstract. Rigging technique introduced in [20] is a convenient way to address the study of null hypersurfaces. It offers in addition the extra benefit of inducing a Riemannian structure on the null hypersurface which is used to study geometric and topological properties on it. In this paper we develop this technique showing new properties and applications. We first discuss the very existence of the rigging fields under prescribed geometric and topological constraints. We consider the completeness of the induced rigged Riemannian structure. This is potentially important because it allows to use most of the usual Riemannian techniques.

Keywords. Lorentzian manifolds, null hypersurface, normalization, rigging vector field, rigged vector field, completeness.

1. Introduction

A null hypersurface in a spacetime is a smooth codimension one submanifold such that the ambient metric degenerates when restricted to it. Null hypersurfaces play an important role in general relativity, as they represent horizons of various sorts (event horizon of a black hole, Killing horizon, etc.) and include lightcones. The main drawback to study them as part of standard submanifold theory is the degeneracy of the induced metric. Some attempts to overcome this difficulty have had remarkable success. In [11], the approach consists in fixing a geometric data formed by a null section and a screen distribution on the null hypersurface. This allows to induce some geometric objects such as a connection, a null second fundamental form and Gauss-Codazzi type equations. In [22], the author uses the quotient vector bundle $TM/TM^\perp$ to ”get rid” of the degeneracy of the induced metric. Returning to the approach in [11], the basic question is how to reduce as much as possible the arbitrary choices and to have a reasonable coupling between the properties of the null hypersurface and the ambient space. In [20], the authors used the rigging technique to study null hypersurfaces. It is based on the arbitrary choice of a unique vector field in a neighborhood of the null hypersurface, called rigging vector field, from which is constructed both a null section defined on the null hypersurface, called rigged vector field, and a screen distribution. This rigging technique has also the advantage
to induce on the whole null hypersurface a Riemannian structure coupled with the rigging, which is used as a bridge to study the null hypersurface. The null geometry of the hypersurface is related to the properties of the induced Riemannian structure on the hypersurface, allowing handle it using Riemannian geometry. The question now arise of knowing weather it is always possible to operate a choice of a rigging vector field with fixed geometric properties (closedness, conformality, causality conditions, etc.) but also with geometric prescribed properties for the induced rigged Riemannian structure (completeness, pinching constraints, geodesibility, etc.). This is our concern in the present paper. The fact that there is a positive answer to a reasonable amount of the above questions reinforces our opinion that the rigging technique can be a good tool in this theory.

In Section 2 we review some facts about null hypersurfaces, fix notations and give two technical lemmas. Obstruction results involving both topology and prescribed geometric conditions on the rigging vector field are established in Section 3 e.g. Theorem 3.1. The completeness properties of the induced Riemannian metric are considered in Section 4. The first part is concerned with some splitting results on the hypersurface equipped with its rigged Riemannian structure. This allows us to get completeness sufficient conditions in Robertson-Walker spaces, e.g. Theorem 4.1 and Proposition 4.3. After this, we consider the case of Generalized-Robertson-Walker (GRW) spaces. We show that there are natural rigging using the warping function leading to a complete induced Riemannian structure e.g. Proposition 4.4. Finally, we show using closedness argument on the rigging field and compacity of the screen leaves that the induced Riemannian structure is complete e.g. Theorem 4.9. In Section 5 we establish some results on null hypersurfaces under completeness assumption of the induced Riemannian metric. In subsection 5.1 we establish some estimates on mean curvature on null hypersurfaces with complete rigged Riemannian structure e.g. Theorem 5.1, Theorem 5.5, Theorem 5.7. Finally, Section 5.2 deals with null hypersurfaces for which the screen shape operator is semi definite. We prove some obstruction results on the existence of closed geodesics e.g. Proposition 5.10 and show under a completeness condition that the manifold structure of the null hypersurface (say) $M$ in a 3-dimensional simply connected Lorentzian manifold with no closed null curve is diffeomorphic to the plane or the cylinder e.g. Theorem 5.13. Finally, we investigate about the existence of topologically closed totally geodesic null hypersurfaces in Robertson-Walker spaces and prove non existence of lightlike line in some cases e.g. Theorem 5.16 and Corollary 5.17.

2. Normalization and rigged Riemannian structure

Let $(\overline{M}, \overline{g})$ be a $(n + 2)$-dimensional Lorentzian manifold and $M$ a null hypersurface in $\overline{M}$. This means that at each $p \in M$, the restriction $\overline{g}|_{T_pM}$ is degenerated, that is there exists a non-zero vector $U \in T_pM$ such that
\( \mathcal{F}(U,X) = 0 \) for all \( X \in T_pM \). Hence, in null setting, the normal bundle \( TM^\perp \) of the null hypersurface \( M^{n+1} \) is a rank 1 vector subbundle of the tangent bundle \( TM \), contrary to the classical theory of non-degenerate hypersurfaces for which the normal bundle has trivial intersection \( \{0\} \) with the tangent one playing an important role in introducing the main induced geometric objects on \( M \). Let us start with the usual tools involved in the study of such hypersurfaces according to [11]. They consist in fixing on the null hypersurface a geometric data formed by a null section and a screen distribution. By \textit{screen distribution} on \( M^{n+1} \), we mean a complementary bundle of \( TM^\perp \) in \( TM \). It is then a rank \( n \) non-degenerate distribution over \( M \). In fact, there are infinitely many possibilities of choices for such a distribution. Each of them is canonically isomorphic to the factor vector bundle \( TM/TM^\perp \). For reasons that will become obvious in few lines below, let us denote such a distribution by \( \mathcal{S}(N) \). We then have,

\[
(2.1) \quad TM = \mathcal{S}(N) \oplus TM^\perp,
\]

where \( \oplus \) denotes the orthogonal direct sum. From [11], it is known that for a null hypersurface equipped with a screen distribution, there exists a unique rank 1 vector subbundle \( tr(TM) \) of \( TM \) over \( M \), such that for any non-zero section \( \xi \) of \( TM^\perp \) on a coordinate neighborhood \( \mathcal{U} \subset M \), there exists a unique section \( N \) of \( tr(TM) \) on \( \mathcal{U} \) satisfying

\[
(2.2) \quad \mathcal{g}(N,\xi) = 1, \quad \mathcal{g}(N,N) = \mathcal{g}(N,W) = 0, \quad \forall W \in \mathcal{S}(N)|_{\mathcal{U}}.
\]

Then \( TM \) admits the splitting:

\[
(2.3) \quad TM|_{\mathcal{M}} = TM \oplus tr(TM) = \{TM^\perp \oplus tr(TM)\} \oplus \mathcal{S}(N).
\]

We call \( tr(TM) \) a \textit{(null) transverse vector bundle} along \( M \). In fact, from (2.2) and (2.3) one shows that, conversely, a choice of a transversal bundle \( tr(TM) \) determines uniquely the screen distribution \( \mathcal{S}(N) \). A vector field \( N \) as in (2.2) is called a \textit{null transverse vector field} of \( M \). It is then noteworthy that the choice of a null transversal vector field \( N \) along \( M \) determines both the null transverse vector bundle, the screen distribution \( \mathcal{S}(N) \) and a unique radical vector field, say \( \xi \), satisfying (2.2).

Before continuing our discussion, we need to clarify the (general) concept of rigging for our null hypersurface.

**Definition 2.1.** Let \( M \) be a null hypersurface in a Lorentzian manifold. A rigging for \( M \) is a vector field \( \zeta \) defined on some open set containing \( M \) such that \( \zeta_p \notin T_pM \) for each \( p \in M \).

Given a rigging \( \zeta \) in a neighborhood of \( M \) in \( (\mathcal{M},\mathcal{g}) \), let \( \alpha \) denote the 1-form \( \mathcal{g} \)-metrically equivalent to \( \zeta \), i.e \( \alpha = \mathcal{g}(\zeta,\cdot) \). Take \( \omega = i^*\alpha \), being \( i : M \hookrightarrow \mathcal{M} \) the canonical inclusion. Next, consider the tensors

\[
(2.4) \quad \tilde{g} = \mathcal{g} + \alpha \otimes \alpha \quad \text{and} \quad \tilde{g} = i^*\tilde{g}.
\]

It is easy to show that \( \tilde{g} \) defines a Riemannian metric on the (whole) hypersurface \( M \). The \textit{rigged vector field} of \( \zeta \) is the \( \tilde{g} \)-metrically equivalent
vector field to the 1-form \( \omega \) and it is denoted by \( \xi \). In fact the rigged vector field \( \xi \) is the unique lightlike vector field in \( M \) such that \( \bar{g}(\xi, \xi) = 1 \). Moreover, \( \xi \) is \( \bar{g} \)-unitary. A screen distribution on \( M \) is given by
\[
\mathcal{S}(\zeta) = TM \cap \zeta^\perp.
\]
It is the \( \bar{g} \)-orthogonal subspace to \( \xi \) and the corresponding null transverse vector field to \( \mathcal{S}(\zeta) \) is
\[
N = \zeta - \frac{1}{2} \bar{g}(\zeta, \zeta) \xi.
\]

A null hypersurface \( M \) equipped with a rigging \( \zeta \) is said to be normalized and is denoted \((M, \zeta)\) (the latter is called a normalization of the null hypersurface). A normalization \((M, \zeta)\) is said to be closed (resp. conformal) if the rigging \( \zeta \) is closed i.e the 1-form \( \alpha \) is closed (resp. \( \zeta \) is a conformal vector field, i.e there exists a function \( \rho \) on the domain of \( \zeta \) such that \( L_\zeta \bar{g} = 2\rho \bar{g} \)). We say that \( \zeta \) is a null rigging for \( M \) if the restriction of \( \zeta \) to the null hypersurface \( M \) is a null vector at each point in \( M \).

Let \( \zeta \) be a rigging for a null hypersurface in a Lorentzian manifold \((\mathcal{M}, \bar{g})\). The screen distribution \( \mathcal{S}(\zeta) = \ker \omega \) is integrable whenever \( \omega \) is closed, in particular if the rigging is closed. On a normalized null hypersurface \((M, \zeta)\), the Gauss and Weingarten formulas are given by
\[
\nabla_X Y = \nabla_X Y + B(X, Y) N, \quad \nabla_X N = -A_N X + \tau(X) N, \quad \nabla_X P Y = \nabla_X P Y + C(X, P Y) \xi, \quad \nabla_X \xi = -\star A_\xi X - \tau(X) \xi,
\]
for any \( X, Y \in \Gamma(TM) \), where \( \nabla \) denotes the Levi-Civita connection on \((\mathcal{M}, \bar{g})\), \( \nabla \) denotes the connection on \( M \) induced from \( \nabla \) through the projection along the null transverse vector field \( N \) and \( \nabla \) denotes the connection on the screen distribution \( \mathcal{S}(\zeta) \) induced from \( \nabla \) through the projection morphism \( P \) of \( \Gamma(TM) \) onto \( \Gamma(\mathcal{S}(\zeta)) \) with respect to the decomposition \( (2.1) \).

The \((0, 2)\) tensor \( B \) is the null second fundamental form on \( TM \), \( \star A_\xi \) the shape operator on \( TM \) with respect to the rigged vector field \( \xi \) and \( \tau \) a 1-form on \( TM \) defined by
\[
\tau(X) = \bar{g}(\nabla_X N, \xi).
\]

The null second fundamental form \( B \) is symmetric, whereas the tensor \( C \) is not in general. The following holds
\[
B(X, Y) = g(\star A_\xi X, Y), \quad C(X, P Y) = g(A_N X, Y) \quad \forall X, Y \in \Gamma(TM),
\]
and
\[
B(X, \xi) = 0, \quad \star A_\xi \xi = 0.
\]
It follows from (2.11) that the integral curves of $\xi$ are pregeodesics in both $\overline{M}$ and $(M, \nabla)$, as $\nabla_{\xi} \xi = \nabla_{\xi} \xi = -\tau(\xi) \xi$.

A null hypersurface $M$ is said to be totally umbilic (resp. totally geodesic) if there exists a smooth function $\rho$ on $M$ such that at each $p \in M$ and for all $u, v \in T_p M$, $B(p)(u, v) = \rho(p)\overline{g}(u, v)$ (resp. $B$ vanishes identically on $M$). These are intrinsic notions on any null hypersurface in the sense that they are independent of the normalization. Note that $M$ is totally umbilic (resp. totally geodesic) if and only if $\star A_\xi = \rho P$ (resp. $\star A_\xi = 0$). It is noteworthy to mention that the shape operators $\star A_\xi$ and $A_N$ are $\mathcal{S}(\zeta)$-valued.

The induced connection $\nabla$ is torsion-free, but it does not preserve $g$ except $M$ is totally geodesic. In fact we have for all tangent vector fields $X, Y$ and $Z$ in $TM$,

$$\nabla_X g(Y, Z) = B(X, Y) \omega(Z) + B(X, Z) \omega(Y).$$

The trace of $\star A_\xi$ is the null mean curvature of $M$, explicitly given by

$$H_p = \sum_{i=2}^{n+1} \overline{g}(\star A_\xi(e_i), e_i) = \sum_{i=2}^{n+1} B(e_i, e_i),$$

being $(e_2, \ldots, e_{n+1})$ an orthonormal basis of $\mathcal{S}(\zeta)$ at $p$.

The (shape) operator $\star A_\xi$ is self-adjoint as the null second fundamental form $B$ is symmetric. However, this is not the case for the operator $A_N$ as it is shown in the following lemma.

**Lemma 2.2.** [5] For all $X, Y \in \Gamma(TM)$,

$$\overline{g}(A_N X, Y) - \overline{g}(A_N Y, X) = \tau(X) \alpha(Y) - \tau(Y) \alpha(X) - d\alpha(X, Y).$$

In case the normalization is closed the 1-form $\tau$ is related to the shape operator of $M$ as follows.

**Lemma 2.3.** Let $(M, \zeta)$ be a closed normalization of a null hypersurface $M$ in a Lorentzian manifold. Then

$$\tau = -\overline{g}(A_N \xi, \cdot) + \tau(\xi)\alpha.$$

In particular if $\tau(\xi) = 0$, then $A_N \xi = -\tau^*\overline{g}$.

**Proof.** By the closedness of $\alpha$, the condition

$$X \cdot \alpha(Y) - Y \cdot \alpha(X) - \alpha([X, Y]) = 0$$

is equivalent to

$$\overline{g}(\nabla_X N, Y) = \overline{g}(\nabla_Y N, X).$$

Then by the weingarten formula, we get

$$\overline{g}(-A_N X, Y) + \tau(X) \alpha(Y) = \overline{g}(-A_N Y, X) + \tau(Y) \alpha(X).$$

In this relation, take $Y = \xi$ to get

$$\tau(X) = -\overline{g}(A_N \xi, X) + \tau(\xi) \alpha(X).$$
which gives the desired formula.

Assume now that $\tau(\xi) = 0$. Then,
$$
\tau(X) = -\tilde{g}(A_N\xi, X) = -\tilde{g}(A_N\xi, X),
$$
for all $X \in TM$, as $A_N\xi \in \mathcal{X}(\zeta)$. Hence, $A_N\xi = -\tau^\sharp\tilde{g}$. \qed

3. Compact null hypersurfaces

The existence of a rigging vector for a null hypersurface is the first step in the rigging technique. It is clear that in general it is not possible to choose a rigging vector field, so it is interesting to identify the situations where you can not choose it. Despite the trivial cases where there is an obstruction due to the existence of a nowhere zero vector, the rigged vector, on a compact null hypersurface which force it to have zero Euler characteristic, there are more subtle situations that we explore here. Given a compact null hypersurface $M$ in a Lorentzian manifold $(\overline{M}, \overline{g})$, we give some restriction on the geometric properties of the admissible rigging of $M$ due to the topology of $M$ that can prevent the existence of some kind of normalization.

**Theorem 3.1.** Let $(\overline{M}, \overline{g})$ be a Lorentzian manifold and $M$ a compact null hypersurface in $\overline{M}$ with trivial first De Rham cohomology group $H^1(M, \mathbb{R})$. Then $M$ admits no closed normalization.

**Proof.** Suppose $M$ is compact and suppose that $b_1(M) = 0$. If there exists a closed rigging $\zeta$ then the 1-form $\omega = i^*\alpha$ is closed and there exists a function $f$ on $M$ such that $df = \omega$, that is $\tilde{\nabla}f = \xi$. As a consequence, we have $\tilde{g}(\tilde{\nabla}f, \tilde{\nabla}f) = 1$ which is not possible as $f$ has at least one critical point on the compact manifold $M$. \qed

This allows us to prove the following result.

**Corollary 3.2.** Let $(\overline{M}, \overline{g})$ be a Lorentzian manifold with a closed timelike vector field. Then there is no compact simply connected null hypersurface in $\overline{M}$.

**Proof.** Let $M$ be a compact null hypersurface in $\overline{M}$. Since $(\overline{M}, \overline{g})$ has a closed timelike vector field say $\zeta$, the later can be used (due to signature considerations) as a rigging for $M$. If we suppose in addition $\pi_1(M) = 0$ which implies that $b_1(M) = 0$ we get a contradiction using above Theorem 3.1. We conclude that if $M$ is compact then $b_1(M) \geq 1$ and hence $M$ is not simply connected. \qed

**Remark 3.3.** In fact, the above proof shows that if $(\overline{M}, \overline{g})$ has a closed timelike vector field, then there is no compact null hypersurface with trivial first De Rham cohomology group in $\overline{M}$.

**Proposition 3.4.** Let $(\overline{M}, \overline{g})$ be a simply connected Lorentzian manifold, then there is no closed normalization for any compact null hypersurface in $\overline{M}$.
Proof. Suppose there exists a compact null hypersurface in $\overline{M}$ with a closed normalization $\zeta$, then $\alpha = \overline{\theta}(\zeta, \cdot)$ is a closed 1-form on $\overline{M}$ and since $\overline{M}$ is simply connected, there exists $f : \overline{M} \to \mathbb{R}$ such that $\alpha = df$. This implies that the $\overline{g}$-equivalent 1-form $\omega$ to the rigged vector field $\xi$ satisfies

$$\omega = i^{\star} \alpha = i^{\star} df = d(i^{\star}f) = d(f \circ i).$$

It follows that $\nabla(f \circ i) = \xi$ and then $\overline{g} \left( \nabla(f \circ i), \nabla(f \circ i) \right) = 1$ which is a contradiction because $f \circ i$ has at least one critical point. □

**Definition 3.5** \cite{4}. A normalized null hypersurface $(M, \zeta)$ of a semi-Riemannian manifold, is screen conformal if the shape operators $A_N$ and $\check{A}_{\xi}$ are related by

$$A_N = \varphi^* A_{\xi}$$

where $\varphi$ is a non-vanishing smooth function on $M$.

As stated in the following theorem, such class of lightlike hypersurfaces has a geometry which is essentially the same as that of their chosen screen distribution.

**Theorem 3.6** \cite{4}. Let $(M, S(\zeta))$ be a screen conformal lightlike hypersurface of a semi-Riemannian manifold $(\overline{M}, \overline{g})$. Then the screen distribution is integrable. Moreover, $M$ is totally geodesic (resp. totally umbilical or minimal) in $\overline{M}$ if and only if any leaf $M'$ of $S(\zeta)$ is totally geodesic (resp. totally umbilical or minimal) in $\overline{M}$ as a codimension 2 nondegenerate submanifold.

Our aim is to show that in a 4-dimensional Lorentzian manifold, compact null hypersurfaces with finite fundamental group can not admit such normalizations. We prove first the following:

**Proposition 3.7.** Let $\zeta$ be a rigging for a compact null hypersurface $M$ in a Lorentzian manifold $(\overline{M}, \overline{g})$ of constant curvature. If the screen $\mathcal{F}(\zeta)$ is conformal and the first De Rham cohomology group $H^1(M, \mathbb{R})$ is trivial, then $M$ is totally geodesic.

Proof. Since $M$ is screen conformal there exists a non vanishing function $\rho$ defined on $M$ such that $A_N = \rho \check{A}_{\xi}$. From the Gauss-Codazzi equations, see \cite{11} Page 95, Eq. (3.12)]

$$\overline{g}(R(X,Y) \xi, N) = C(Y, \check{A}_{\xi}X) - C(X, \check{A}_{\xi}Y) - 2 \overline{\tau}(X,Y), \quad \forall X, Y \in \Gamma(TM).$$

(3.2)

But the left hand side of (3.2) vanishes since $\overline{M}$ has constant curvature, and $\xi$ is orthogonal to both $X$ and $Y$. Moreover,

$$C(Y, \check{A}_{\xi}X) - C(X, \check{A}_{\xi}Y) = \overline{g}(A_N Y, \check{A}_{\xi}X) - \overline{g}(A_N X, \check{A}_{\xi}Y) = 0$$
since $A_N = \rho \hat{A}_\xi$. Using the fact that $H^1(M, \mathbb{R})$ is trivial, there exists a function (say) $\phi$ defined on $M$ such that $\tau = d\phi$. Define a new rigging vector field by $\hat{\zeta} = \exp(-\phi)\zeta$, so $\hat{N} = \exp(-\phi)N$. Moreover, it follows (from [2], Lemma 2.1) that $\hat{\tau} = \tau + d(\ln(\exp(-\phi)) = 0$ as $\tau = d\phi$. Denote respectively by $\hat{\xi}$, $\hat{H}$, $\hat{\star}A\hat{\xi}$ the rigged vector field, the mean curvature function and the screen shape operator form of $\hat{\zeta}$, we have ([5], Remark 3)

$$\text{Ric}(\hat{\xi}) = \hat{\xi}(\hat{H}) + \hat{\tau}(\hat{\xi})\hat{H} - |\hat{\star}A\hat{\xi}|^2.$$  

But $\text{Ric}(\hat{\xi}) = 0$ since $M$ has constant curvature and $\hat{\tau}(\hat{\xi}) = 0$, it follows that $\hat{\xi}(\hat{H}) - |\hat{\star}A\hat{\xi}|^2 = 0$. Using the inequality $|\hat{\star}A\hat{\xi}|^2 \geq \frac{1}{n} \hat{H}^2$, we obtain $\hat{\xi}(\hat{H}) - \frac{1}{n} \hat{H}^2 \geq 0$, and since $\hat{\xi}$ is complete ($M$ being compact) we get that $\hat{H} = 0$. From the relation $\hat{\xi}(\hat{H}) - |\hat{\star}A\hat{\xi}|^2 = 0$, it follows that $|\hat{\star}A\hat{\xi}|^2 = 0$ which leads to $\hat{\xi} = 0$. We conclude that $M$ is totally geodesic. □

We can get now the following result.

**Proposition 3.8.** Let $(\overline{M}^4, \overline{g})$ be a 4-dimensional Lorentzian manifold of constant curvature and $M$ a compact null hypersurface. If $M$ has finite fundamental group then there is no normalization such that $M$ is screen conformal.

**Proof.** Let $M$ be as above. Suppose there is a normalization such that $M$ is screen conformal. Since $M$ has finite fundamental group, the first De Rham cohomology group $H^1(M, \mathbb{R})$ is trivial. It follows from Proposition 3.7 that $M$ is totally geodesic. Elsewhere, $M$ being screen conformal, $\mathcal{S}(\zeta)$ is integrable and induces a foliation on $M$. We show that the leaves of the screen distribution $\mathcal{S}(\zeta)$ are totally geodesic in $(M, \tilde{g})$. For this, recall (from [20], Proposition 3.7) that for $X$ and $Y$ in $\mathcal{S}(\zeta)$,

$$\tilde{\nabla}_X Y = \hat{\nabla}_X Y - \tilde{g}(\tilde{\nabla}_X \xi, Y)\xi,$$

but we also have

$$\tilde{g}(\tilde{\nabla}_X \xi, Y) + \tilde{g}(\tilde{\nabla}_Y \xi, X) = L_\xi \tilde{g}(X, Y) = -2B(X, Y).$$

Now, since $\mathcal{S}(\zeta)$ is integrable, we have $\tilde{g}(\tilde{\nabla}_X \xi, Y) = \tilde{g}(\tilde{\nabla}_Y \xi, X)$. It follows that $\tilde{g}(\tilde{\nabla}_X \xi, Y) = -B(X, Y)$ which implies that

$$\tilde{\nabla}_X Y = \hat{\nabla}_X Y + B(X, Y)\xi.$$

In other words, the second fundamental form of each leaf of $\mathcal{S}(\zeta)$ in $(M, \tilde{g})$ is $B$ and then each of them is totally geodesic in $(M, \tilde{g})$ as $M$ is totally geodesic in $(\overline{M}^4, \overline{g})$. It follows that there exits a totally geodesic codimension one foliation on the compact 3-manifold $M$, hence $M$ must have infinite fundamental group (see [7]), which is a contradiction. □
4. Completeness of \((M, \tilde{g})\)

On a normalized null hypersurface in a Lorentzian manifold there is a bridge between the Riemannian geometry of the couple \((M, \tilde{g})\) and the null geometry of \(M\). The key is to use Riemannian techniques, so it worths to investigate on its completeness. We consider first this problem in some particular Lorentzian manifold (Robertson-Walker spaces, generalized Robertson-Walker spaces) and finish with the case of arbitrary Lorentzian manifold.

It is known that a totally umbilic null hypersurface with a closed normalization splits locally as a twisted product, the decomposition being global if \(M\) is simply connected and the rigged vector field complete, \([20, \text{Theorem } 5.3]\). We show here that if moreover it admits a closed conformal rigging in an ambient space form, the local twisted product structure of the rigged metric is in fact a warped product. Elsewhere, we show that in a Robertson-Walker space case, using a specific rigging, we also get warped decomposition of totally umbilic null hypersurfaces. This allows us to state some sufficient conditions for \((M, \tilde{g})\) to be complete.

**Theorem 4.1.** Let \((\overline{M}^{n+2}, \overline{g})\) be a Lorentzian manifold with constant curvature (with \(n \geq 2\)) and \(M\) a totally umbilic null hypersurface admitting a closed conformal normalization \(\zeta\). Then given \(p \in M\), the Riemannian structure \((M, \tilde{g})\) is locally isometric to a warped product \((\mathbb{R} \times S, dr^2 + f^2 g_0)\) where \(S\) is the leaf of \(\mathcal{S}(\zeta)\) through \(p\), and \(g_0\) is a conformal metric to \(g|_S\). Moreover, if \(M\) is simply connected and the rigged vector field \(\xi\) complete, the decomposition is global.

**Proof.** Using \([20, \text{Theorem } 5.3]\), the only point we are going to show is the warped decomposition of \((M, \tilde{g})\).

In \([20, \text{Theorem } 4.8]\) it is shown that for \(U, V \in TM\) the following holds,

\[
R(U, V)\xi - \tilde{R}(U, V)\xi = \overline{g}(R(U, V)\xi, N)\xi - \tau(U)\tilde{A}_\xi(V) + \tau(V)\tilde{A}_\xi(U).
\]

We also know that if \(\zeta\) is closed and conformal, the 1-form \(\tau\) vanishes identically. Using the Gauss-Codazzi equation we have \(R(U, V)\xi = \overline{R}(U, V)\xi\). Finally \(\overline{R}(U, V)\xi = 0\) since \((\overline{M}, \overline{g})\) has constant curvature and the above equality becomes \(\tilde{R}(U, V)\xi = 0\) for all tangent vector fields \(U\) and \(V\). Then, \(\tilde{Ric}(X, \xi) = 0\) for all \(\mathcal{S}(\zeta)\)-valued vector field \(X\) (in fact for all tangent vector field \(X\)). The result follows from the mixed Ricci flat condition, \([12, \text{Theorem } 1]\).

**Remark 4.2.** The global decomposition of \((M, \tilde{g})\) as warped product still holds in Theorem 4.1 if \(M\) is not simply connected but the rigging is a gradient vector field (see \([20, \text{Remark } 5.4]\)).

In case \(\overline{M} = I \times f L\) is a Robertson-Walker space, we use the classical rigging \(\zeta = f \frac{\partial}{\partial t}\) which is a gradient conformal vector field to get the following.

**Proposition 4.3.** Let \(\overline{M} = I \times f L\) be a Robertson-Walker space and \(M\) a totally umbilic null hypersurface equipped with the (natural) rigging \(\zeta = f \frac{\partial}{\partial t}\).
Proposition 4.4. Let $\overline{M} = I \times_f L$ be a Generalized-Robertson-Walker space and $M$ a null hypersurface equipped with the rigging $\xi = f \frac{\partial}{\partial t}$ such that $h \circ i$ is a proper function on $M$ (where $h$ is any primitive of $-f$). Then its rigged Riemannian structure $(M, \overline{g})$ is complete.

Remark 4.5. In case $L$ is compact, $h : \overline{M} \rightarrow \mathbb{R}$ is proper if and only if $\overline{M}$ is null complete. Recall also that if $h : \overline{M} \rightarrow \mathbb{R}$ is proper and $M$ is a closed subset then $h \circ i : M \rightarrow \mathbb{R}$ is also proper. Hence

Proposition 4.6. Let $\overline{M} = I \times_f L$ be a Generalized-Robertson-Walker space with compact Riemannian factor $L$. If $\overline{M}$ is null complete, any topologically closed null hypersurface $M$ in $\overline{M}$ is $\overline{g}$-complete for the usual rigging $\xi = f \frac{\partial}{\partial t}$.

Example 4.7. Consider $\overline{M} = \mathbb{R} \times_{S^2} L$ with $L$ compact. It is null complete and then any (topologically) closed null hypersurface $M$ in $\overline{M}$ is $\overline{g}$-complete for the usual rigging $\xi = f \frac{\partial}{\partial t}$. 

Proof. 1. Since $\overline{M} = I \times_f L$ is a Robertson-Walker space and $L$ being of constant curvature $c$, we know that

$$R(U, V)W = \frac{(f')^2 + c}{f^2} (g(V, W)U - g(U, W)V)$$

and $R(U, V) \frac{\partial}{\partial t} = 0$ for all $U, V, W$ tangent to the factor $L$. Using the classical rigging $\xi = f \frac{\partial}{\partial t}$ which is closed (in fact a gradient) and conformal, decompose the associated rigged vector field as $\xi = a \frac{\partial}{\partial t} + X_0$ with $X_0 \in TL$; we have $\overline{g}(X_0, X) = 0 \forall X \in \mathcal{S}(\xi)$. Remark also that $\mathcal{S}(\xi) \subset TL$. Taking into account the above considerations, we get $R(Y, X)\xi = 0, \forall X, Y \in \mathcal{S}(\xi)$. Following the proof of previous Theorem 4.1 we get that $\overline{R}(Y, X)\xi = 0$, $\forall X, Y \in \mathcal{S}(\xi)$ and then $\overline{Ric}(X, \xi) = 0$ for all $\mathcal{S}(\xi)$-valued vector field $X$. The conclusion follows as in the last theorem. Taking into account Remark 4.2 the global decomposition holds if $\xi$ is complete.

2. From point 1, we have that $(M, \overline{g})$ is globally isometric to a warped product $(\mathbb{R} \times S, dr^2 + f^2 g_0)$, and being $S$ compact, it is complete. \qed
For GRW spaces with complete Riemannian factors, we show the following.

**Theorem 4.8.** Let $\mathcal{M} = \mathbb{R} \times f L$ be a Generalized-Robertson-Walker space with complete Riemannian factor $(L, g_0)$ and $M$ be a topologically closed null hypersurface of $\mathcal{M}$. Then, the Riemannian structure $(M, \tilde{g})$ induced by the rigging $\zeta = \sqrt{2} \frac{\partial}{\partial t}$ is complete.

*Proof.* The Lorentzian metric on $\mathcal{M}$ is given by $\mathcal{g} = -dt^2 + f^2 g_0$. Then using the rigging $\zeta = \sqrt{2} \frac{\partial}{\partial t}$ and the first equality in (2.4) we get

$$\tilde{g} = dt^2 + f^2 g_0$$

which shows that $(\mathcal{M}, \tilde{g})$ is a complete Riemannian manifold as $(L, g_0)$ is complete. Then, since $M$ is topologically closed, using the second equality in (2.4) we see that $(M, \tilde{g})$ is a complete Riemannian manifold.

The following theorem gives some sufficient conditions to get a complete induced Riemannian structure on a given null hypersurface in any Lorentzian manifold. It is an improvement of Proposition 4.3 point 2.

**Theorem 4.9.** Let $(\mathcal{M}^{n+2}, \mathcal{g})$ be a Lorentzian manifold and $(M, \zeta)$ a closed normalization of a connected non compact null hypersurface. If $\xi$ is complete and $\mathcal{S}(\zeta)$ has compact leaves then $(M, \tilde{g})$ is complete.

*Proof.* Let $\Phi$ be the flow of $\xi$. Since $\xi$ is complete, closed with compact orthogonal leaves,

$$\Phi : \mathbb{R} \times L \longrightarrow M$$

$$(t, p) \longmapsto \Phi_t(p)$$

is a diffeomorphism where $L$ is a leaf of $\mathcal{S}(\zeta)$ [18, Proof of Lemma 3.1], [19, Theorem 4.1]. Suppose the inverse of $\Phi$ decomposes as

$$\Phi^{-1} : M \longrightarrow \mathbb{R} \times L$$

$$x \longmapsto (f(x), \psi(x))$$

so we have $\nabla f = \xi$ which is nowhere zero, $f$ is a submersion. Since $|\nabla f| = 1$ and $\xi$ is complete, there exists a diffeomorphism $F : \mathbb{R} \times f^{-1}(0) \rightarrow M$, [18, Theorem 6.2]. Moreover, $pr_1 : \mathbb{R} \times f^{-1}(0) \rightarrow \mathbb{R}$ being the projection on the first factor we have $f = pr_1 \circ F^{-1}$. By hypothesis $M$ is connected and $F$ a diffeomorphism so $f^{-1}(0)$ is connected too. It follows that $f^{-1}(0)$ is a leaf of $\mathcal{S}(\zeta)$ which is compact, so $pr_1$ is a proper map. Thus, $f$ is a proper map. Since its gradient is bounded, we conclude that $(M, \tilde{g})$ is complete.

**Theorem 4.10.** Let $(\mathcal{M}, \mathcal{g})$ be a Lorentzian manifold furnished with a proper function $f$ whose gradient is timelike everywhere. Then for any topologically closed null hypersurface in $\mathcal{M}$, the rigging $\zeta = \nabla f$ makes $(M, \tilde{g})$ complete.
Proof. Let us denote by $h$ the restriction of $f$ on $M$. Since $M$ is closed in $\overline{M}$, $h$ is also a proper function on $M$. Considering the rigging $\zeta = \nabla f$, a straightforward argument shows that $\tilde{\nabla} h = \xi$, so $\tilde{g}(\tilde{\nabla} h, \tilde{\nabla} h) = 1$. It follows that $h$ is a proper function on $M$ whose gradient is bounded, then $(M, \tilde{g})$ is complete. \hfill \Box

5. Applications

Let $(M, \zeta)$ be a normalized null hypersurface of a Lorentzian manifold $\overline{M}$, we show several results under the hypothesis that $(M, \tilde{g})$ is a complete Riemannian manifold. In the first part we show that the non-normalized null mean curvature of $M$ is strongly controlled by the ricci curvature of $M$ evaluated on the associated rigged vector field $\xi$. We investigate also about mean curvature of null hypersurfaces all of whose screen principal curvatures are constant. The second part deals with null hypersurface with semi-definite shape. Non existence of closed geodesic in $(M, \tilde{g})$ is proved for some special cases which allows us to give a classification theorem e.g. Theorem 5.13 and corollary 5.14. Finally, we investigate about the existence of topologically closed totally geodesic null hypersurfaces in Robertson-Walker spaces.

5.1. Ricci estimates and mean curvature boundedness. Given a normalized null hypersurface $(M, \zeta)$ of a Lorentzian manifold $\overline{M}$, we prove some results about $M$ under hypothesis on the ricci curvature of $\overline{M}$ evaluated on the associated rigged vector field $\xi$.

**Theorem 5.1.** Let $(\overline{M}, \overline{g})$ be a Lorentzian manifold and $(M, \zeta)$ a closed normalization of a null hypersurface such that $\tau(\xi) = 0$. Assume $M$ to be $\bar{g}$–complete and there exists a nonnegative constant $k$ such that $\text{Ric}(\xi) \geq -k$. Then we have $|H| \leq k$ where $H$ stands for the (non normalized) mean curvature of $M$.

The proof uses the following.

**Theorem 5.2.** Let $(M, g)$ be a complete connected Riemannian manifold such that there exists $f : M \to \mathbb{R}$ satisfying $|\nabla f| = 1$. Suppose that $\text{Ric}(\nabla f, \nabla f) \geq -k$ ($k$ a nonnegative constant), then $|\Delta f| \leq k$.

We give now the proof of Theorem 5.1.

**Proof.** Let $\pi : (\overline{M}, \overline{g}) \to (M, g)$ be the semi-Riemannian universal covering of $\overline{M}$. Define $M' = \pi^{-1}(M)$ which is a null hypersurface because $\pi$ is a local isometry and call $i' : M' \to \overline{M}$ the canonical inclusion. The closed rigging $\zeta$ can be lifted to a closed rigging $\zeta'$ on $M'$. Call $\alpha' = \pi' \alpha$ its equivalent 1-form being $\alpha$ the equivalent 1-form to $\zeta$. The rigged metric on $M'$ is
\(\bar{g}' = i^*(g' + \alpha' \otimes \alpha')\). Using the following commutative diagram

\[
\begin{array}{ccc}
\bar{M}' & \xrightarrow{\pi'} & \bar{M} \\
\downarrow{i'} & & \downarrow{i} \\
M' & \xrightarrow{\pi} & M
\end{array}
\]

where \(\pi\) is the canonical projection from \(M'\) onto \(M\), it is clear that \(\omega' = \pi^*\omega\)
where \(\omega\) is the equivalent 1-form to the rigged field \(\xi\) on \(M\), and \(\bar{g}' = \pi^*\bar{g}\). If we call \(\xi'\) the rigged vector field on \(M'\) induced by \(\xi\), we have \(\pi_*(\xi') = \xi \circ \pi\).

Using that \(\pi\) is a local isometry, we have \(\tau'(\xi') = 0\), \(\bar{g}'\) is complete and \(\bar{Ric'}(\xi') \geq -k\).

Since \(\bar{M}\) is simply connected and \(\xi'\) is closed, we know there exists \(f : M' \rightarrow \mathbb{R}\) such that \(\nabla'f = \xi'\) and thus \(\bar{g}'(\nabla'f, \nabla'f) = 1\). Moreover, for a closed normalization, we have (see [20])

\[\bar{Ric'}(\xi') = \bar{Ric}(\xi') + \tau'(\xi')H'\]

being \(H'\) the null mean curvature of \(M'\). Since \(\tau'(\xi') = 0\), then we get \(\bar{Ric}(\xi') = \bar{Ric}(\xi')\). From this, we get \(\bar{Ric}(\nabla'f) = \bar{Ric}(\xi') \geq -k\). Finally using the \(\bar{g}'\)-completeness and Theorem 5.2 we have \(|\Delta'f| \leq k\) on each connected component of \(M'\), so on \(M'\) itself. But \(H' = -\text{div'}(\nabla'f) = \varepsilon\Delta'f\) (\(\varepsilon = \pm 1\) according to the sign convention of the Laplacian), then \(|H'|_{g'} \leq k\).

Using again that \(\pi\) is a local isometry and \(H' = \pi^*H\) we get \(|H| \leq k\).

**Corollary 5.3.** Let \((\bar{M}^{n+2}, \bar{g})\) be a Lorentzian manifold and \((M, \zeta)\) be a closed normalization of a totally umbilic null hypersurface with umbilicity factor \(\rho\) (i.e. \(B = \rho g\)) such that \(\tau(\xi) = 0\). If there exists a nonnegative constant \(k\) such that \(\bar{Ric}(\xi) \geq -k\) and \(M\) is \(\bar{g}\)-complete then it holds \(|\rho| \leq \frac{k}{n}\).

**Proof.** The proof is straightforward using \(H = np\).

Since any Riemannian metric on a compact manifold is complete, the following also holds:

**Corollary 5.4.** Let \((\bar{M}, \bar{g})\) be a Lorentzian manifold admitting \((M, \zeta)\) a closed normalization of a compact null hypersurface and suppose that \(\tau(\xi) = 0\). Assume there exists a nonnegative constant \(k\) such that \(\bar{Ric}(\xi) \geq -k\). Then we have \(|H| \leq k\) where \(H\) stands for the (non normalized) mean curvature of \(M\).

**Theorem 5.5.** Let \((\bar{M}^{n+2}, \bar{g})\) be a simply connected Lorentzian manifold and \((M, \zeta)\) a closed normalization of a compact null hypersurface such that \(\tau(\xi) = 0\). Suppose \(k\) is a positive constant such that \(\bar{Ric}(\xi) \geq -nk^2\). If \(M\) is \(\bar{g}\)-complete and \(|H| = nk\), then the hypersurface \(M\) endowed with the Riemannian structure \(\bar{g}\) is isometric to the warped product \(\mathbb{R} \times e^{\pm kt}Z\) where \(Z\) inherits a Riemannian structure from \(\bar{M}\). In particular \(M\) is totally umbilic.

The proof makes use of the following.
**Theorem 5.6** ([24, Theorem 1.1). Let \((M, g)\) be a complete connected Riemannian manifold such that there exists \(f : M \rightarrow \mathbb{R}\) satisfying \(|\nabla f| = 1\). Suppose

\[
Ric(\nabla f, \nabla f) \geq -n \frac{\phi''(f(x))}{\phi(f(x))} \quad \text{(resp.} \quad Ric(\nabla f, \nabla f) \geq -n \frac{(\phi^*)''(f(x))}{\phi^*(f(x)))} \text{).}
\]

If \(\Delta f = -n \frac{\phi'(f(x))}{\phi(f(x))} \) (resp. \(\Delta f = n \frac{\phi'(f(x))}{\phi(f(x))} \)) then

\[
\Phi : \mathbb{R} \times \phi Z \rightarrow M
\]

\[
(s, p) \mapsto \psi_s(p)
\]

is an isometry (resp.)

\[
\Phi : \mathbb{R} \times \phi^* Z \rightarrow M
\]

\[
(s, p) \mapsto \psi_s(p)
\]

is an isometry where \(\psi_s\) is the flow of \(\nabla f\), \(\phi : \mathbb{R} \rightarrow \mathbb{R}^+\) a smooth positive function, \(\phi^* (t) = \phi(-t)\) and \(Z = f^{-1}(0)\).

**Proof.** (of Theorem 5.6)

We know that there exists \(f : \overline{M} \rightarrow \mathbb{R}\) such that \(\bar{\nabla} f = \xi\) and then \(\bar{g} (\bar{\nabla} f, \bar{\nabla} f) = 1\). Let \(\phi(t) = e^{kt} (t \in \mathbb{R})\). It follows that \(\frac{\phi'(f(x))}{\phi(f(x))} = k^2\) and \(\frac{\phi'(f(x))}{\phi(f(x))} \) is constant. We deduce using the assumption on the ricci curvature that \(\bar{\text{Ric}}(\xi) = \text{Ric}(\xi) \geq -n \frac{\phi'(f(x))}{\phi(f(x))}\) that is \(\bar{\text{Ric}}(\bar{\nabla} f, \bar{\nabla} f) \geq -n \frac{\phi'(f(x))}{\phi(f(x))}\). Moreover, if \(H = -nk\) then \(H = \bar{\Delta} f = -n \frac{\phi'(f(x))}{\phi(f(x))}\). Using Theorem 5.6 we conclude that \((M, \bar{g})\) is isometric to the warped product \(\mathbb{R} \times e^{kt} Z\) where \(Z = f^{-1}(0)\) is endowed with the induced Riemannian metric. If \(H = nk\), \((M, \bar{g})\) is isometric to the warped product \(\mathbb{R} \times e^{-kt} Z\). Finally, since each \(Z\) with the Riemannian structure induced from the warped structure is totally umbilic in \((M, \bar{g})\), the null hypersurface \(M\) is totally umbilic. [20 Corollary 3.14].

**Theorem 5.7.** Let \((\overline{M}, \overline{g})\) be a simply connected Lorentzian manifold and \((M, \zeta)\) a \(\overline{g}\)-complete closed normalization of a null hypersurface \(M\), all of whose screen principal curvatures are constant. Then it holds \(|H| \leq \left| \dot{A}_\xi \right|^2\).

**Proof.** We know that \(\bar{\text{Ric}}(\xi) = \xi(H) + \tau(\xi) H - \left| \dot{A}_\xi \right|^2\) ([14]). Observe that since the screen principal curvatures are constant, \(H\) and \(\dot{A}_\xi\) are constant quantities and that for closed normalizations, \(\bar{\text{Ric}}(\xi) = \text{Ric}(\xi) - \tau(\xi) H\). Then,

\[
\bar{\text{Ric}}(\xi) = -\left| \dot{A}_\xi \right|^2 = \text{constant}.
\]
Using the fact that $\overline{M}$ is simply connected and $\zeta$ is closed, we know there exists $f : M \to \mathbb{R}$ such that $\nabla f = \xi$ and thus $\tilde{g}(\nabla f, \nabla f) = 1$. By Theorem 5.7 it follows that $|\tilde{\Delta} f| = |H| \leq |A_\xi|^2$. □

**Corollary 5.8.** Let $(\overline{M}^{n+2}, \tilde{g})$ be a simply connected Lorentzian manifold and $(M, \zeta)$ a $\tilde{g}$-complete closed normalization of a non-totally geodesic null hypersurface $M$ all of whose screen principal curvatures are non-negative constants. Then at least one of them is greater or equal to 1.

**Proof.** Since all the eigenvalues of $A_\xi$ are non-negative, the inequality in Theorem 5.7 becomes $H \leq |A_\xi|^2$. Let denote the eigenvalues by $\lambda_i$. If we suppose that all of them are less than 1, then we have $\lambda_i \geq \lambda_i^2$. But as $M$ is non-totally geodesic, there exist $i_0$ such that $\lambda_{i_0}$ is positive and then $\lambda_{i_0} > \lambda_{i_0}^2$. It follows that $H > |A_\xi|^2$, which is in contradiction with $H \leq |A_\xi|^2$. □

**Corollary 5.9.** Let $(\overline{M}^{n+2}, \tilde{g})$ be a simply connected Lorentzian manifold and $(M, \zeta)$ a $\tilde{g}$-complete closed normalization of a proper totally umbilic null hypersurface $M$ with constant umbilicity factor $\rho$. Then $|\rho| \geq 1$.

**Proof.** Because $\rho$ is constant, all the eigenvalues of $A_\xi$ are constant. Using theorem (5.7), we have $|H| \leq |A_\xi|^2$. But since $M$ is proper totally umbilic, $H = n\rho \neq 0$ and $|A_\xi|^2 = n\rho^2$ so the inequality becomes $n|\rho| \leq n\rho^2$ and we get $|\rho| \geq 1$. □

### 5.2. Null Hypersurfaces with Semi-definite Shape $B$.

Positive definiteness of the second fundamental form of hypersurfaces have many consequences in Riemannian geometry. A well-known theorem due to Hadamard [17] (see also [16, Theorem 2.4]) states that if the second fundamental form of a compact immersed hypersurface $M$ of a Euclidean space is positive definite, then $M$ is embedded as the boundary of a convex body. This also implies an equivalence between definiteness of the second fundamental form and the fact that $M$ is orientable and its (spherical) Gauss map is a diffeomorphism. Equivalently, the Gaussian curvature of $M$ is nowhere-vanishing. In the present section, we present some facts about definiteness of the second fundamental form $B$ and geodesics relative to the rigged Riemannian structure. Recall that if a complete Riemannian manifold supports a convex function, the latter is constant along any closed geodesic, [6, Proposition 2.1].
Proposition 5.10. Let \((M, \zeta)\) be a closed normalization of a null hypersurface \(M\) in a simply connected Lorentzian manifold \((\overline{M}, \overline{g})\). Assume \(M\) is \(\overline{g}\)-complete and \(B\) restricts to a definite form on \(\mathcal{S}(\zeta)\). Then \((M, \overline{g})\) contains no closed geodesics.

Proof. By a change of rigging \(\zeta \leftarrow -\zeta\) if necessary, we can suppose without loss of generality that \(M\) is connected and that the restriction of \(B\) to \(\mathcal{S}(\zeta)\) is negative definite which implies that \(B\) is negative semi-definite on \(M\). Also, by the simply connectedness of \(\overline{M}\) and the closedness of the normalization, we know that there exists \(f : M \to \mathbb{R}\) such that \(\overline{\nabla}f = \xi\). Let us remark that fibers of \(f\) are leaves of \(\mathcal{S}(\zeta)\) (see proof of Theorem 4.9). Using \([20, \text{Proposition 3.15}].\), we have \(\overline{\text{Hess}}f(U, V) = -B(U, V)\) for all \(U, V \in TM\). \(B\) being negative semi-definite, \(f\) is a convex function on \(M\). Suppose that there exists a closed geodesic \(\gamma\) in \(M\). Then \(f \circ \gamma\) is a constant say \(c\) (as stated above \([6]\)) and \(\gamma\) is contained in the leaf \(f^{-1}(c)\) of \(\mathcal{S}(\zeta)\), hence \(\gamma' \in \mathcal{S}(\zeta)\) and then \(\overline{\text{Hess}}f((\gamma, \gamma)) > 0\), which gives the contradiction as \(\overline{\text{Hess}}f((\gamma, \gamma)) = (f \circ \gamma)'u = 0; f \circ \gamma\) being constant. We conclude that \((M, \overline{g})\) contains no closed geodesics. \(\square\)

Remark 5.11. The proposition remain true if \(M\) is not simply connected but the first De Rham cohomology group \(H^1(M, \mathbb{R})\) is trivial or the one form \(\omega\) is exact so that the rigged vector field \(\xi\) is a gradient vector field. Since for proper totally umbilic null hypersurfaces the restriction of \(B\) to the screen structure \(\mathcal{S}(\zeta)\) is always definite form, we easily deduce the following.

Corollary 5.12. Let \((M, \zeta)\) be a closed normalization of a proper totally umbilic null hypersurface \(M\) in a simply connected Lorentzian manifold \((\overline{M}, \overline{g})\) such that \(M\) is \(\overline{g}\)-complete. Then \((M, \overline{g})\) contains no closed geodesics.

The next result gives a restriction on the topology of proper totally umbilic null surface (in 3-dimensional Lorentzian manifold) which can admit a \(\overline{g}\)-complete Riemannian metric for a given rigging.

Theorem 5.13. Let \((M, \zeta)\) be a closed normalization of a null surface \(M\) non totally geodesic at any point in a simply connected 3-dimensional Lorentzian manifold \((\overline{M^3}, \overline{g})\) such that \(M\) is \(\overline{g}\)-complete, then \(M\) is homeomorphic to the plane or the cylinder.

Proof. From corollary 5.12 the null hypersurface \((M, \overline{g})\) contains no closed geodesics. It follows from the classification of complete surfaces without closed geodesic (see \([21], \text{Theorem 3.2}\) that \(M\) is homeomorphic to the plane or the cylinder. \(\square\)

Corollary 5.14. Let \(\overline{M} = \mathbb{R} \times fL\) be a 3-dimensional Generalized-Robertson-Walker (GRW) space with complete Riemannian factor \((L, \overline{g_0})\). Any topologically closed null surface and non totally geodesic at any point is homeomorphic to the plane or the cylinder.
Proof. Let $M$ be a topologically closed proper totally umbilic null surface. Consider the normalizing rigging $\zeta = \sqrt{2\frac{\partial}{\partial t}}$ for $M$. Then from Theorem 4.8 $(M,\tilde{g})$ is complete. Moreover the 1-form $\omega$ is exact. From Remark 5.11 and Theorem 5.13 $M$ is homeomorphic to the plane or the cylinder. \hfill $\Box$

5.3. Totally geodesic null hypersurfaces in Robertson-Walker spaces.

Totally geodesic null hypersurfaces are intensively used in general relativity as they represent horizons of various sorts (Non expanding horizon, isolated horizon, Killing horizon, etc.). We investigate here the existence of totally geodesic null hypersurfaces in Robertson-Walker spaces. For this, we use the Hilbert theorem which we recall here.

Theorem 5.15. ([10], [9]) Let $\Sigma$ be a complete surface with negative constant curvature $K$. Then, there exists no isometric immersion $f: \Sigma \to \tilde{M}^3(c)$ (with $K < -1$ for $c = -1$), where $\tilde{M}^3(c)$ stands for the simply-connected complete Riemannian 3-space with constant sectional curvature $c = -1, 0, 1$.

We prove the following.

Theorem 5.16. Let $\overline{M} = \mathbb{R} \times_f \tilde{M}^3(c)$ be a Robertson-Walker space. Then the followings hold:

1. If $c = 0$ or $c = -1$ and $f$ is strictly monotone, then there is no topologically closed totally geodesic null hypersurface in $\overline{M}$.

2. If $c = 1$ and $f'(t) > 1 \forall t$, then there is no topologically closed totally geodesic null hypersurface in $\overline{M}$.

Proof. Let $\overline{M} = \mathbb{R} \times_f \tilde{M}^3(c)$ be a Robertson-Walker space. Suppose there exist a topologically closed totally geodesic null hypersurface $M$ in $\overline{M}$. Consider the normalizing rigging $\zeta = \sqrt{2\frac{\partial}{\partial t}}$ for $M$. Let, $\Pi: \mathbb{R} \times \tilde{M}^3(c) \to \mathbb{R}$ be the projection on the first factor. Then a leaf of $\mathcal{S}(\zeta)$ is the intersection of $M$ with a fiber of $\Pi$, hence a leaf of $\mathcal{S}(\zeta)$ is a closed subset contained in some slice $\{t_0\} \times \tilde{M}^3(c)$. Let us call $g$ the Riemannian metric on $\tilde{M}^3(c)$. Since the Lorentzian metric on $\overline{M}$ is given by $\overline{g} = -dt^2 + f^2 g$, using the equalities in (2.1) we get that $\overline{g}_{|S} = f^2(t_0)g$ so that $(S,\tilde{g} = \frac{1}{f^2(t_0)}\overline{g}_{|S})$ is a complete surface isometrically immersed in $\tilde{M}^3(c)$. Elsewhere, the following relation (2.10) holds:

\[
K(X,Y) = \tilde{K}^S(X,Y) - C(X,X)B(Y,Y) - B(X,X)C(Y,Y) + 2C(X,Y)B(X,Y)
\]

$\forall X,Y \in \mathcal{S}(\zeta)$, where $K(X,Y)$ is the sectional curvature in $(\overline{M},\overline{g})$ and $\tilde{K}^S(X,Y)$ the induced sectional curvature from $(M,\tilde{g})$ that is $\tilde{K}^S(X,Y)$ is the Gauss curvature of $(S,\tilde{g}_{|S})$. Since the null hypersurface $M$ is totally geodesic, $B = 0$. Hence $\tilde{K}^S(X,Y) = K(X,Y) = \frac{c(f')^2}{f}$. Note that $S$ being contained in some slice $\{t_0\} \times \tilde{M}^3(c)$, $\tilde{K}^S(X,Y) = \frac{c(f')^2(t_0)}{f^2(t_0)}$ and is constant. Finally since $\tilde{g} = \frac{1}{f^2(t_0)}\overline{g}_{|S}$, the Gauss curvature of the surface
\((S, \tilde{g})\) is \(\tilde{K} = c - (f')^2(t_0)\) if \(c = 0\) or \(c = -1\) and \(f\) is strictly monotone or \(c = 1\) and \(f'(t) > 1 \forall t\) then \((S, \tilde{g})\) has negative constant Gauss curvature (with \(\tilde{K} < -1\) in case \(c = -1\)). The contradiction follows from the Hilbert Theorem. \(\Box\)

In \([8]\), Theorem IV.1, Galloway shows that if a Lorentzian manifold is null complete and satisfy the null convergence condition then any null line is conained in a smooth (topologically) closed achronal totally geodesic null hypersurface. So under null completeness and null convergence condition hypothesis, the absence of topologically closed totally geodesic null hypersurface implies the absence of null line. The following holds:

**Corollary 5.17.** Let \(\overline{M} = \mathbb{R} \times f M^3(c)\) be a null complete Robertson-Walker space satisfying the null convergence condition. Then we have:

1. If \(c = 0\) or \(c = -1\) and \(f\) is strictly monotone, \(\overline{M}\) contains no lightlike line.
2. If \(c = 1\) and \(f'(t) > 1 \forall t\), \(\overline{M}\) contains no lightlike line.
