Meta-analysis of robotic and laparoscopic surgery for treatment of rectal cancer

Shuang Lin, Hong-Gang Jiang, Zhi-Heng Chen, Shu-Yang Zhou, Xiao-Sun Liu, Ji-Ren Yu

Abstract

AIM: To conduct a meta-analysis to determine the relative merits of robotic surgery (RS) and laparoscopic surgery (LS) for rectal cancer.

METHODS: A literature search was performed to identify comparative studies reporting perioperative outcomes for RS and LS for rectal cancer. Pooled odds ratios and weighted mean differences (WMDs) with 95% confidence intervals (95% CIs) were calculated using either the fixed effects model or random effects model.

RESULTS: Eight studies matched the selection criteria and reported on 661 subjects, of whom 268 underwent RS and 393 underwent LS for rectal cancer. Compared the perioperative outcomes of RS with LS, reports of RS indicated favorable outcomes considering conversion (WMD: 0.25; 95% CI: 0.11-0.58; \( P = 0.001 \)). Meanwhile, operative time (WMD: 27.92, 95% CI: -13.43 to 69.27; \( P = 0.19 \)); blood loss (WMD: -32.35, 95% CI: -86.19 to 21.50; \( P = 0.24 \)); days to passing flatus (WMD: -0.18, 95% CI: -0.96 to 0.60; \( P = 0.65 \)); length of stay (WMD: -0.04; 95% CI: -2.28 to 2.20; \( P = 0.97 \)); complications (WMD: 1.05; 95% CI: 0.71-1.55; \( P = 0.82 \)) and pathological details, including lymph nodes harvested (WMD: 0.41, 95% CI: -0.67 to 1.50; \( P = 0.46 \)), distal resection margin (WMD: -0.35, 95% CI: -1.27 to 0.58; \( P = 0.46 \)), and positive circumferential resection margin (WMD: 0.54, 95% CI: 0.12-2.39; \( P = 0.42 \)) were similar between RS and LS.

CONCLUSION: RS for rectal cancer is superior to LS in terms of conversion. RS may be an alternative treatment for rectal cancer. Further studies are required.

Key words: Robotic surgery; Laparoscopic surgery; Rectal cancer; Da Vinci robotic system; Meta-analysis

INTRODUCTION

Over the past 30 years, laparoscopic surgery (LS) has revolutionized general surgical practice, above all affecting
surgery of the gastrointestinal (GI) tract\sup{[6,7,10]}. However, with regard to rectal cancer, there are several technical drawbacks to LS, including limited range of motion of instruments in a narrow pelvic cavity, related loss of dexterity, and an inadequate visual field associated with unstable camera view and assistant’s traction, which are not under the surgeon’s control\sup{[6,7,10]}. Technical advantages of the da Vinci robotic system could overcome the limitations of LS for rectal cancer, by giving the surgeon a 3D view, better ergonomics, enhanced dexterity, precision and control due to the 3D optical system and EndoWrist® Instruments.

Although surgical robots have been successfully applied to a number of disciplines, most notably urological and cardiac procedures\sup{[6,7,10]}, robotic rectal surgery remains in its infancy. Most studies have been limited by small sample size and a single institution design. To overcome these limitations, a meta-analysis of studies comparing robotic surgery (RS) and LS for rectal cancer should be performed. The aim of this meta-analysis was to determine the relative merits of RS and LS for rectal cancer.

### MATERIALS AND METHODS

#### Study selection

The Pubmed, Embase, Cochrane Library, Ovid, and Web of Science databases were searched systematically for all articles published before June 2011 to compare RS and LS for rectal cancer. The terms used for the search were: “robotic” and “rectal cancer”. Only studies in the English language were considered for inclusion. Reference lists of all retrieved articles were manually searched for additional studies. Two reviewers independently extracted the data from each study. All relevant text, tables and figures were reviewed for data extraction. Discrepancies between the two reviewers were resolved by discussion and consensus.

#### Criteria for inclusion and exclusion

For inclusion in the meta-analysis, a study had to fulfill the following criteria: (1) compare the outcomes of RS and LS, regardless of other diseases; (2) report on at least one of the outcome measures mentioned below; and (3) if dual (or multiple) studies were reported by the same institution and/or authors, the one of higher quality or the most recent publication was included in the analysis.

Abstracts, letters, editorials and expert opinions, reviews without original data, case reports and studies lacking control groups were excluded. The following studies or data were also excluded: (1) the outcomes and parameters of patients were not clearly reported (e.g., with no clearly reported outcomes of SD; (2) it was impossible to extract the appropriate data from the published results; and (3) there was overlap between authors or centers in the published literature.

#### Outcomes of interest

The following outcomes were used to compare the two operative techniques: (1) intraoperative data, which included operative time, blood loss and conversion; (2) postoperative data, which included complication, days to passing flatus, and length of stay; and (3) pathological details, which included lymph nodes harvested, distal resection margin (DRM), and positive circumferential resection margin (PCRM) which was defined as a circumferential resection margin (CRM) of ≤ 1 mm.

#### Data extraction

Two reviewers independently extracted the following parameters from each study: (1) first author and year of publication; (2) study population characteristics; (3) number of subjects operated on with each technique; and (4) intraoperative data, postoperative data, and pathological details.

#### Statistical analysis

The meta-analysis was performed using the Review Manager (RevMan) software, version 4.2.2. We analyzed dichotomous variables using estimation of odds ratios with a 95% confidence interval (95% CI) and continuous variables using weighted mean difference (WMD) with a 95% CI. Pooled effect was calculated using either the fixed effects model or random effects model. Heterogeneity was evaluated by $\chi^2$ and $I^2$. We considered heterogeneity to be present if the $I^2$ statistic was > 50%. $P < 0.05$ was considered significant.

### RESULTS

#### Selection of trials

The initial search strategy retrieved 154 publications, after screening all titles, abstracts, and full-text. A total of eight studies met our entry criteria and were retrieved for more detailed evaluation. The characteristics of these eight studies are summarized in Table 1\sup{[6,8,12]}. Eight studies [six non-randomized controlled trials (NRCTs), two randomized controlled trials (RCTs)] included a total of 661 patients: 268 in the RS group and 393 in the LS group. Two studies were conducted in United States\sup{[7,13]}, three in Korea\sup{[6,8,12]}, two in Italy\sup{[10,11]}, and one in Romania\sup{[9]}. The sample size of each study varied from six to 123 patients. In the included studies, six were considered as level of evidence 3, and the remaining 2 as level of evidence 2 (according to the grading of the Centre of Evidence-Based Medicine, Oxford, United Kingdom; http://www.cebm.net/index.aspx?o=5653).

In these studies, patients in the two groups were matched for operation time\sup{[6,9,11,12]}, blood loss\sup{[6,9,11]}, conversion\sup{[6,9,11]}, complications\sup{[6,9,11]}, days to passing flatus\sup{[6,9,11]}, length of stay\sup{[6,9,11]}, lymph nodes harvested\sup{[6,8,11,12]}, DRM\sup{[6,8,11,12]}, and PCRM\sup{[6,7,10]}.

#### Meta-analysis of intraoperative data

In four studies, operative time showed that there was no significant difference between the two groups. Analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: 27.92, 95% CI: 5215 WJG | www.wjgnet.com
-13.43 to 69.27; \( P = 0.19 \) (Figure 1A).

In two studies, blood loss did not differ significantly between the two groups. Analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: -32.35, 95% CI: -86.19 to 21.50; \( P = 0.24 \)) (Figure 1B).

In all eight studies, conversion was found to be significantly lower in the RS group than in the LS group. Moreover, analysis of the pooled data revealed that conversion for RS was significantly lower by 0.25-fold (WMD: -0.18, 95% CI: -0.96 to 0.60; \( P = 0.65 \)) (Figure 1D).

**Meta-analysis of postoperative outcomes**

In two studies, number of days to passing flatus was significantly lower in the RS group than in the LS group. Meanwhile, analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: -13.43 to 69.27; \( P = 0.19 \) ) (Figure 1A).

In three studies, length of stay was found to be no different in the RS group and the LS group. Meanwhile, analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: -0.18, 95% CI: -0.96 to 0.60; \( P = 0.65 \) ) (Figure 1D).

In three studies, complications were found to be no different in the RS group and the LS group. Meanwhile, analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: -0.18, 95% CI: -0.96 to 0.60; \( P = 0.65 \) ) (Figure 1D).

**Meta-analysis of pathological details**

In the four studies, lymph nodes harvested showed that there was no significant difference between the two groups. Analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: 0.41, 95% CI: -0.67 to 1.50; \( P = 0.46 \) ) (Figure 1G).

In three studies, DRM was found to be significantly lower in the RS group than the LS group. Meanwhile, analysis of the pooled data revealed that the two groups did not differ significantly in this regard (WMD: -0.35, 95% CI: -1.27 to 0.58; \( P = 0.46 \) ) (Figure 1H).

**Heterogeneity**

A significant heterogeneity was recognized in the following two factors: operative time, blood loss, days to passing flatus, length of stay and DRM.

**DISCUSSION**

Meta-analysis could be used to evaluate the existing literature in both qualitative and quantitative ways by comparing and integrating the results of different studies and taking into account variations in characteristics that could influence the overall estimate of the outcome of interest. Although meta-analysis has traditionally been applied and best confined to RCTs, meta-analytical techniques using NRCTs might be a good method in some clinical settings in which either the number or the sample size of RCTs was insufficient. To the best of our knowledge, this was the first comprehensive meta-analysis comparing RS versus LS for rectal cancer.

RS is often perceived as being more time-consuming, because of the additional set-up time required. It usually requires two steps for rectal cancer treatment. After dissection of the left colon and sigmoid colon and division and ligation of the inferior mesenteric vessels, the da Vinci system must be moved for the next step. However, moving the da Vinci system is a time-consuming and difficult procedure because the robotic devices are heavy and bulky. This meta-analysis revealed that there was no significant difference in operative time between RS and LS. This finding could be attributable to the shortened learning curve, and it has been suggested that the intuitive controls of robotic systems, more comparable with open surgery, could shorten the learning curve, even in the hands of relatively inexperienced laparoscopic surgeons. As we overcame the learning curve with experience and prevented collisions by properly positioning the robotic ports, the operation time decreased. There was no significant difference in blood loss when comparing RS and LS.

Conversion to open surgery and complications are critical in minimally invasive rectal cancer surgery, because converted patients have higher complication rates and, in one series at least, worse oncological outcomes. Conversion rate was significantly lower in the RS group than in the LS group. Lower conversion with RS might have been due to superior exposure and visualization of the operating field in the pelvis, thanks to the ability of the fixed fourth arm to grip and maneuver organs; the ability of the surgeon to move the 3D camera as required; and the greater ease of dissection afforded by the

Test for heterogeneity: $\chi^2 = 5.62$, df = 2 ($P = 0.06$), $I^2 = 64.4\%$

Test for overall effect: $Z = 0.73$ ($P = 0.46$)
Figure 1 Forest plot displaying the results of the meta-analysis on operative time (A), blood loss (B), conversion (C), days to passing flatus (D), length of stay (E), complications (F), lymph nodes harvested (G), distal resection margin (H) and positive circumferential resection margin (I). RS: Robotic surgery; LS: Laparoscopic surgery; OR: Odds ratio; WMD: Weighted mean difference.

In conclusion, the results of this meta-analysis of robotic and laparoscopic surgery for treatment of rectal cancer should be interpreted with caution because of several limitations. First, some data came from NRCTs, and the overall level of clinical evidence was low. It has been reported that NRCTs have found that meta-analysis of well-designed NRCTs can either exaggerate or underestimate the magnitude of measured effects in a study of intervention regardless of quality scores. However, Abrahama et al. have found that meta-analysis of well-designed NRCTs of surgical procedures was probably as accurate as that of RCTs. In fact, six studies included in the present study were NRCTs. Second, there was heterogeneity between the two groups, because it was impossible to match patient characteristics in all studies. We applied a random-effect model to take into consideration between-study variation, and it might have been expected to exert a limited influence. Finally, authors might be more likely to report positive results, and studies with significant outcomes were more likely to be published, so potential publication bias might have been present.

In conclusion, the results of this meta-analysis of 661 patients show that RS is superior to LS for rectal cancer in terms of conversion. Therefore, RS may be an alternative treatment for rectal cancer. Further studies are required to better define its role.
invasive surgery to overcome the technical limitations of laparoscopy, but robotic rectal surgery is controversial because of a lack of well-powered trials.

Research frontiers
Meta-analysis was used to evaluate the relative merits of robotic surgery (RS) and laparoscopic surgery (LS) for rectal cancer in this study.

Innovations and breakthroughs
The meta-analysis reported that RS had favorable outcomes considering conversion, compared with LS for rectal cancer. Meanwhile, operative time, blood loss, days to passing flatus, length of stay, complications and pathological details, including lymph nodes harvested, distal resection margin, and positive circumferential resection margin were similar between RS and LS. This is believed to be the first comprehensive meta-analysis comparing RS and LS for rectal cancer.

Applications
The results of this meta-analysis show that RS is superior to LS in terms of conversion. Therefore, RS may be an alternative treatment for rectal cancer.

Peer review
This paper addressed superiority of RS for rectal cancer, especially due to superior exposure and visualization of the intrapelvic field. This advantage means that surgeons complete the operation without conversion. This paper should be of interest to colorectal surgeons worldwide.
