ABSTRACT

**Background:** Our earlier study on the antiproliferative (APF) activity of leaf extracts of ten Apocynaceae species showed that leaves of *Vallaris glabra* possessed strong and broad-spectrum properties. **Materials and Methods:** In this study, sequential extracts of leaves, flowers and stems, and fractions and isolated compounds from dichloromethane (DCM) leaf extract of *V. glabra* were assessed for APF activity using the sulphorhodamine B (SRB) assay. Apoptotic effect of MDA-MB-231 cancer cells treated with DCM leaf extract of *V. glabra* was studied using Hoechst 33342 dye and caspase colorimetry. **Results:** Both DCM extracts of leaves and flowers possessed broad-spectrum APF activity against HT-29, MCF-7, MDA-MB-231 and SKOV-3 cancer cells. From DCM leaf extract, stearic acid (SA) and ursolic acid (UA) were isolated by column chromatography, and identified by NMR and MS analyses. APF activity of SA from DCM leaf extract displayed weak inhibitory activity and scientific literature showed UA has anticancer properties against those cancer cells used in this study. MDA-MB-231 cancer cells treated with DCM leaf extract and stained with Hoechst 33342 dye provided evidence that the extract had an apoptotic effect on the cells. Caspase colorimetry showed that the apoptotic effect involved activation of caspase-8, -9 and -3, but not caspase-6. **Conclusion:** The potential of *V. glabra* as a candidate species for anticancer drugs warrants further investigation.

Key words: Antiproliferative activity, apoptosis, caspase colorimetry, Hoechst nuclear staining, *Vallaris glabra*

INTRODUCTION

The family Apocynaceae consists of about 250 genera and 2000 species of tropical trees, shrubs and vines.[1] Almost all species of the family produce milky sap. Other characteristic features are simple, opposite or whorled leaves; large, colorful and slightly fragrant flowers with five contorted lobes; and fruits are in pairs. With inclusion of species of Asclepiadaceae, the family has now been enlarged from two to five subfamilies.[2]

In traditional medicine, Apocynaceae species are used to treat gastrointestinal ailments, fever, malaria, pain and diabetes.[1] Apocynaceae species have also been reported to show anticancer properties. Our earlier study on the antiproliferative (APF) activity of leaf extracts of ten Apocynaceae species showed that *Alstonia angustiloba, Calotropis gigantea, Catharanthus roseus, Nerium oleander, Plumeria obtusa* and *Vallaris glabra* displayed positive inhibition.[3,4] *Allamanda cathartica, Cerbera odollam, Dyera costulata* and *Kopsia fruticosa* did not display any APF activity. Dichloromethane (DCM) and DCM: Methanol (MeOH) extracts of *V. glabra* inhibited all six cancer cell lines of MCF-7, MDA-MB-231, HeLa, HT-29, SKOV-3 and HepG2, while the MeOH extract inhibited MCF-7 and HepG2 cells. Results showed that leaves of *V. glabra* possessed strong and broad-spectrum properties. Recently, the botany, uses, phytochemistry and pharmacology of selected Apocynaceae species including *V. glabra* have been reviewed.[5]

In this study, the leaves, flowers and stems of *V. glabra* were sequentially extracted with solvents of increasing polarity. The resultant fractions and compounds isolated from DCM leaf extract from *V. glabra* were assessed for APF activity. Apoptosis of MDA-MB-231 breast cancer cells treated with DCM leaf extract was shown and possible mechanisms were elucidated by caspase colorimetry.
MATERIALS AND METHODS

Plant materials
Leaves, flowers and stems of V. glabra were collected from Kepong (N 3° 12’14”; E 101° 37’50”) in Selangor, Malaysia and identified by Dr. Chan Hung Tuck, former Division Director of Forest Research Institute Malaysia. V. glabra is a woody climber that produces clusters of white flowers [Figure 1] with a scent characteristic of Pandanus amaryllifolius (pandan) leaves or fragrant rice. With brief description of its morphology and location, a voucher specimen of V. glabra was deposited in the herbarium of Monash University Sunway Campus in Malaysia.

Extraction of plant material
Leaves (40 gm), stems (10 gm) and flowers (10 gm) of V. glabra were freeze-dried overnight, ground and sequentially extracted with hexane (Hex), DCM, DCM: MeOH (1:1) and MeOH. For each solvent (50 mL/gm of plant sample), the suspension of ground samples was shaken for 1 h on the orbital shaker. After filtering, the samples were extracted two more times for each solvent. Solvents were removed with a rotary evaporator and the dried extracts were stored at -20°C for further analysis.

Antiproliferative activity
Antiproliferative (APF) activity of extracts, fractions and isolated compounds was assessed for growth inhibitory (GI_50) activity against four types of human cancer cells (HT-29, MCF-7, MDA-MB-231 and SKOV-3) using the sulphorhodamine B (SRB) assay, following the procedures described earlier.[6,7] The measured quantity, GI_50, is the concentration of extract that causes 50% reduction in cell growth.

Human cancer cell lines, obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA), were seeded 24 h prior to treatment in 96-well plates at appropriate densities (30,000 cells/mL for MCF-7; 60,000 cells/mL for MDA-MB-231 and HT-29; and 120,000 cells/mL for SKOV-3) with each well containing 100 µL of cell culture. Extracts (5 mg/mL) were dissolved in 100% DMSO and serially diluted two-fold to concentrations ranging from 3.13-50.0 µg/mL with appropriate medium. As 100 µL of the diluted samples were introduced to the existing 100 µL of cell cultures, the final concentration of extracts ranged from 1.56-25.0 µg/mL. The control cultures were treated with the same volume of DMSO (0.5%). The concentration of DMSO was kept within 1% to avoid any interference with cell viability. After the addition of extracts, the plates were incubated for 48 h. After incubation, the cells were fixed with 50 µL of cold 50% TCA (w/v) and incubated for 1 h at 4°C. The plates were then washed with water and air dried. Cells were stained with 100 µL of 0.4% (w/v) SRB solution diluted with 1% acetic acid followed by incubation for 10 min at room temperature. Unbound dye was removed by washing with 1% acetic acid. Bound stain was then solubilised with 200 µL of 10 mM trizma base.

Absorbance of each well at 505 nm was obtained using a microplate reader. Dose-response curves were plotted to obtain GI_50 calculated using the formula \[\frac{(T_i - T_c)}{(T_i - T)}\] \times 100 = 50 where \(T_i\) is the absorbance of cells treated with extracts or drugs at the end of incubation, \(T_c\) is the absorbance of cells prior to treatment with extracts or drugs and \(T\) is the absorbance of untreated cells treated with vehicle (0.5-1.0% DMSO) at the end of incubation. APF activity is considered to be effective when GI_50 value ≤20 µg/mL.[8]

Isolation of compounds
DCM leaf extract (26 gm) of Vallaris glabra was subjected to column chromatography over Silica gel 60. A solvent system with an increasing polarity gradient was used: Hexane-ethyl acetate (Hex-EtAc) and ethyl acetate-methanol (EtAc-MeOH) to give 13 fractions (D1 to D13).

Fraction D11 (3.26 gm) was passed through Sephadex LH-20 with gradient H_2O-MeOH (50→100% MeOH) to give five sub-fractions (D11-1 to D11-5). Sub-fraction D11-1 (1.38 gm) was then subjected to Chromatorex C18 with gradient H_2O-MeOH (10→100% MeOH) to give six sub-fractions (D11-1-1 to D11-1-6). Sub-fraction D11-1-5 (0.27 gm) was passed through Sephadex LH-20 with gradient CHCl_3-EtAc (0→100% EtAc) to give three sub-fractions (D11-1-5-1 to D11-1-5-3). Sub-fraction D11-1-5-2 (0.16 gm) was passed through Sephadex LH-20 with gradient CHCl_3-EtAc (0→50% EtAc) to give six sub-fractions (D11-1-5-2-1 to D11-1-5-2-6). Sub-fraction D11-1-5-2-2 (86 mg) was subjected to Chromatorex C18 with gradient H_2O-MeOH (10→100% MeOH) to obtain Compound 1 (12 mg).
Fraction D8 of the DCM leaf extract (2.61 gm) was passed through Silica gel 60 using a solvent system of Hex-DCM (20→100% DCM) followed by DCM-Acetone (0→100% Acetone) and finally Acetone-MeOH (0→100% MeOH) to give 27 sub-fractions (D8-1 to D8-27). Sub-fraction D8-19 (0.71 gm) was subjected to Silica gel 60 chromatography by eluting with DCM-EtAc (0→100% EtAc), followed by EtAc-Acetone (0→100% Acetone) and finally Acetone-MeOH (0→100% MeOH) to give 16 sub-fractions (D8-19-1 to D8-19-16). Sub-fraction D8-19-6 (0.09 gm) was again chromatographed on silica gel 60 with Hex-EtAc (10→100% EtAc) to obtain six sub-fractions (D8-19-6-1 to D8-19-6-6). Compound 2 (0.01 gm) was precipitated from sub-fraction D8-19-6-4 (0.02 gm) by dissolving in chloroform with sonication and heat (40°C) followed by chilling overnight at -20°C. The precipitate was recovered by filtration.

Identification of compounds
Compounds were dissolved in a deuterated solvent and subjected to 1H and 13C NMR analysis using a Bruker DRX 300 MHz spectrometer (300 MHz for 1H and 75.4 MHz for 13C) and a Varian Unity Inova 500 MHz spectrometer (500 MHz for 1H and 125.7 MHz for 13C). Chemical shifts were recorded in ppm (δ) using TMS as internal standard. MS analysis was performed by APCI-MS in negative mode using a Thermo Finnigan LCQ Deca spectrometer and EI-MS using a Thermo Finnigan Trace GC-PolarisQ spectrometer.

Hoechst nuclear staining
MDA-MB-231 breast cancer cells treated with DCM leaf extract and stained with Hoechst 33342 dye (Sigma Chemical Co., St. Louis, MO, USA) was performed following protocols previously described.[7] Visualisation of nuclear morphology was performed using Hoechst 33342, a DNA-binding fluorescent dye. MDA-MB-231 breast cancer cells were cultured in 3.5 mm cell-culture dishes with a cover slip placed into each of the dishes and sterilized under UV radiation for 15 min. After culturing of cells overnight, they were treated for 48 h with 1% DMSO as control and with varying concentrations of leaf extract at 1.56, 3.13, 6.25, 12.5, 25.0 and 50.0 µg/mL. After removing the cell culture media, the dishes and cover slips were washed twice with 10% PBS followed by fixing the cells to the cover slips with 3.7% paraformaldehyde (pH 7) for 10 min. The fixing solution was removed and the dishes and cover slips were washed twice with 10% phosphate-buffered saline (PBS). Hoechst 33342 (1 µg/mL) was added directly to the affixed cells and stained in the dark for 10 min before washing twice with 10% PBS. The cover slips were carefully lifted from the dishes, placed onto glass slides with 10 µL of Gel Mount aqueous mounting medium (Sigma) and sealed with nail varnish. The stains cells were visualized at ×40 magnification using an inverted microscope (Olympus BX41) and a UV filter. Images of cells were photographed by a digital Nikon DS-F1c camera using NIS-Elements F software version 3.00.

Caspase colorimetry
MDA-MB-231 cells were treated with varying concentrations (1.56-25.0 µg/mL) of DCM leaf extract. The floating and trypsinised-adherent cells were collected and washed in cold PBS. The cells were lysed by adding 50 µL chilled lysis buffer (BioVision, USA) and incubated on ice for 10 min. The suspension was then centrifuged for 1 min at 10,000 x g. The supernatant containing the cytosolic extract was transferred to a fresh tube and put on ice for assay or stored in aliquots at -80°C for future use.

The protein concentration was determined using the microassay procedure adopted by the manufacturer (Bio-Rad). Protein standards (125-1500 µg/mL) using bovine serum albumin (BSA) were prepared. The standards and samples of protein cell lysates in various dilutions (5 µL) were added into each well of a 96-well microtiter plate. Bio-Rad dye reagent concentrate (250 µL) was added into each well. Control consisted of water in place of the protein sample. The plate was incubated in the dark at room temperature for 30 min before reading absorbance at 595 nm.

Activities of caspase-3, -6, -8 and -9 were determined using the Caspase Colorimetric Assay Kit (BioVision Research, Mountain View, CA, USA) according to the instructions of the manufacturer. Cytosolic protein (200 µg) was diluted to 50 µL cell lysis buffer for each assay in a 96-well plate. To each well, 50 µL of reaction buffer containing 10 mM dithiothreitol (DTT) was added followed by 5 µL of substrate containing 4 mM Asp-Glu-Val-Asp (DEVD)-pNA substrate (caspase-3), 4 mM Val-Glu-Ile-Asp (VEID)-pNA substrate (caspase-6), 4 mM Ile-Glu-Thr-Asp (IETD)-pNA substrate (caspase-8), or 4 mM Leu-Glu-His-Asp (LEHD)-pNA substrate (caspase-9). The plate was then incubated at 37°C for 2 h. At the end of incubation, the plate was read in a microtitre plate reader at 412 nm. Fold-increase in caspase activity was determined by comparing the results of treated samples with those of the control.

RESULTS AND DISCUSSION
APF activity of extracts
Table 1 shows that both DCM extracts of leaves and flowers possessed more broad-spectrum APF activity than stems against HT-29, MCF-7, MDA-MB-231 and SKOV-3 cancer cells. DCM extract of stems and flowers were the most potent against MCF-7 cells compared to the other three sequential
Table 1: Antiproliferative activity of sequential extracts of leaves, flowers and stems of *Vallaris glabra* against four human cancer cell lines

| Plant part | Sequential extract | HT-29 | MCF-7 | MDA-MB-231 | SKOV-3 |
|------------|--------------------|-------|-------|-------------|--------|
| Leaves     | Hex                | -     | -     | -           | -      |

|            | MeOH               | -     | 5.4±1.6 | -           | 1.8±0.2 |

Standard drug

- Xanthorrhizol: 11±0.7 | 8.7±0.8
- Curcumin: 4.1±0.9 | 8.7±0.8
- Tamoxifen: 8.3±0.6 | 4.6±0.5

$GI_{50}$ (µg/mL) is the concentration of extracts resulting in 50% reduction in cell growth in comparison with untreated cells. Values are means ± SD. For each column, values followed by the same superscript (a-d) are not statistically different at P < 0.05 as measured by the Tukey HSD test. HT-29 are human colon cancer cells, MCF-7 and MDA-MB-231 are human breast cancer cells and SKOV-3 are human cervical cancer cells. $GI_{50}$ values of standard drugs of xanthorrhizol, curcumin and tamoxifen against MCF-7 and MDA-MB-231 were used as positive controls.

Extracts. $GI_{50}$ of DCM extract of stems and flowers (both 1.4 ± 0.2 µg/mL) for MCF-7 cells was lower than that of the positive controls. Hexane extract of stems (7.0 ± 0.6 µg/mL) and flowers (3.3 ± 1.0 µg/mL) were more potent against MCF-7 cells than tamoxifen (8.3 ± 0.6 µg/mL) and xanthorrhizol (11 ± 0.7 µg/mL). Hexane flower extract was as effective as curcumin (4.1 ± 0.9 µg/mL). The inhibition of stem extracts was more specific to MCF-7 and SKOV-3 cells. Overall, the screening results show that extracts from three different parts of *V. glabra* possessed effective APF activity.

Identification of compounds

Two compounds were isolated from DCM leaf extract of *V. glabra*. Their appearance, MS and molecular weight are as follows:

**Compound 1: stearic acid**

Amorphous waxy white solid; EI-MS m/z 284 [M⁺]; ¹H NMR (CDCl₃, 300 MHz) δ: 2.37 (2H, t, J = 7.5 Hz, H-2), 1.54 (2H, m, H-3), 1.25–1.33 (28H, H4 to H17), 0.85 (3H, t, J = 6.9 Hz, H-18); ¹³C NMR (CDCl₃, 75.4 MHz) δ: 180 (COO), 34.2 (C-2), 24.7 (C-3), 29.4 (C-4), 29.2–32.2 (C-5 to C-16), 22.7 (C-17), 14.1 (C-18).

**Compound 2: ursolic acid**

Amorphous white powder; APCI-MS m/z 456 [M-H]-; ¹H NMR (CD₃OD, 500 MHz) δ: 5.23 (1H, m, H-12), 3.15 (1H, dd, J = 11.5, 4.5 Hz, H-3), 2.21 (1H, d, J = 11.0 Hz, H-18), 1.08 (3H, H-23), 0.98 (3H, H-27), 0.97 (3H, H-26), 0.96 (3H, H-24), 0.89 (3H, d, J = 6.5 Hz, H-29), 0.85 (3H, d, J = 6.5 Hz, H-30), 0.78 (3H, H-25); ¹³C NMR (CD₃OD, 125.7 MHz) δ: 182 (C-28), 140 (C-13), 127 (C-12), 79.7 (C-3), 56.8 (C-5), 54.4 (C-18), 48.5 (C-9 and C-17), 43.3 (C-14), 40.8 (C-8), 40.4 (C-19 and C-20), 40.0 (C-4), 39.9 (C-1), 38.1 (C-10 and C-22), 34.4 (C-7), 31.8 (C-21), 29.2 (C-15), 28.8 (C-23), 27.9 (C-2), 25.3 (C-16), 24.4 (C-11), 24.1 (C-27), 21.6 (C-30), 19.5 (C-6), 17.8 (C-29), 17.7 (C-26), 16.4 (C-25), 16.1 (C-24).

The MS and the ¹H and ¹³C NMR data of the above two compounds matched those of the previously reported data on stearic acid[9,10] and ursolic acid.[11,12] Stearic acid or octadecanoic acid (IUPAC name) is a saturated fatty acid with an 18-carbon chain. Its molecular formula is C₃₆H₇₂O₂ and molecular weight is 284.5. Ursolic acid is a pentacyclic...
triterpene acid. Its molecular formula is $C_{30}H_{48}O_{3}$ and molecular weight is 456.7.

Stearic acid (SA) isolated from leaves of *Vallaris glabra* is a major essential oil found in Apocynaceae species such as leaves and flowers of *Catharanthus roseus*,[13] and leaves of *Alstonia boonei*. Ursolic acid (UA), widely found in plants, is a compound that possesses many biological activities such as antioxidative, anti-inflammatory, anticaner and hepatoprotective, as well as the ability to induce apoptosis.[13] In Apocynaceae, it has been isolated from species such as *Alstonia scholaris* and *Plumeria rubra*.[17]

Other compounds isolated from leaf extracts of *V. glabra* included three caffeoylquinic acids (CQAs) and two cardiac glycosides.[18,19] Isolated from MeOH leaf extract of *V. glabra*, the CQAs were identified as 3-CQA, 4-CQA and 5-CQA or chlorogenic acid (CGA).[18] Compared to flowers of *Lonicera japonica* (the commercial source of CGA), 5-CQA content was two times higher and 3-CQA and 4-CQA content was about 16 times higher. One of the two cardiac glycosides isolated was identified as acoscimperoside P, 2'-acetate. This compound was active in Hedgehog signaling inhibition and showed strong cytotoxicity against human prostate cancer cell line.[19] The other compound was a new cardiac glycoside.

**APF activity of isolated compounds**

Results showed that SA isolated from DCM leaf extract displayed weak inhibitory activity against HT-29 (59 ± 6.0 µg/mL), MCF-7 (102 ± 16 µg/mL), MDA-MB-231 (73 ± 8.8 µg/mL) and SKOV-3 (78 ± 4.8 µg/mL) cancer cells. Against MCF-7 and MDA-MB-231, SA had much higher GI$_{50}$ values of 49 ± 6 and 31 ± 4 µg/mL, respectively than standards such as curcumin (4.1 ± 0.9 and 8.7 ± 0.8 µg/mL) and tamoxifen (8.3 ± 0.6 and 4.6 ± 0.5 µg/mL), respectively.[7] Previous studies on the APF properties of SA have reported variable results. SA had no APF effect on 14 human leukemic cell lines.[23] Using clonogenic assay, SA was found to be toxic against five human cancer cell lines,[21] one of which was HT-29 with IC$_{50}$ of 7.65 µg/mL, which is in variance with our value of 59 µg/mL. The discrepancy could be due to the different methods used in assessing APF activity. Against HOG-1 cervical cancer cells, SA at 21.3 µg/mL inhibited the growth of HOG-1 cells after 48 h in culture and at 35.6 µg/mL, cell death occurred.[22] SA isolated from aerial parts of *Oldenlandia diffusa* inhibited the growth of human hepatoma cells of HepG2 and Hep3B, but not human normal cells of WRL-68.[23] Against HepG2 (IC$_{50}$ of 25.6 µg/mL) and Hep3B (IC$_{50}$ of 37.0 µg/mL), SA was more effective than other fatty acids.

The yield of UA isolated from DCM extract (only 0.01 gm) was too low for analysis of its inhibitory activity. Nevertheless, there is a wealth of literature reports on the anticancer properties of UA, including those of the cancer cells used in this study. Most of these reports concluded that UA is a potent chemo-preventive agent for cancer.

UA was reported to be a potent inhibitor of MCF-7 cell proliferation, exerting an early cytostatic response at G1 phase of cell cycle followed by cell death.[24] UA induced apoptosis, PARP cleavage and also decreased Bel-2 protein in MCF-7 cells, supporting the hypothesis that UA induces apoptosis through the intrinsic mitochondrial pathway.[25] Against MDA-MB-231 breast cancer cells, UA was reported to exert a dose- and time-dependent inhibitory effect on the migration and invasion of MDA-MB-231 breast cancer cells at non-cytotoxic concentrations.[26] UA isolated from rosemary has been shown to inhibit cell proliferation and induce apoptosis in MDA-MB-231.[27] The study showed that apoptosis was induced through both mitochondrial death pathway and extrinsic death receptor dependent pathway in MDA-MB-231 cells. Against HT-29 colon cancer cells, UA has been reported to have strong antiproliferative and apoptotic effects.[28] Another study showed that UA inhibited cell growth by inhibiting the EGFR/MAPK pathway.[29] Against SKOV-3 ovary cancer cells, UA exerted cytotoxicity with IC$_{50}$ of 50 µM.[30] Apoptotic bodies were observed in treated SKOV-3 cells. The cytotoxic activity of some UA derivatives was stronger than UA against SKOV-3 cancer cells.[31]

**Table 2: Antiproliferative activity of fractions from DCM leaf extract**

| Fraction No. | Growth inhibition (GI$_{50}$) |
|--------------|-------------------------------|
|              | HT-29 | MCF-7 | MDA-MB-231 | SKOV-3 |
| 3            | 5.2 ± 0.5a | 3.4 ± 0.7a | 5.4 ± 1.1a | 4.0 ± 0.7a |
| 8            | 5.3 ± 0.6a | 3.8 ± 0.7a | 3.5 ± 0.5a | 4.6 ± 0.3a |
| 9            | 5.4 ± 0.9a | 4.2 ± 0.6a | 10 ± 3.3a | 2.7 ± 0.7a |
| 10           | 3.5 ± 0.8a | 2.1 ± 0.2a | 5.2 ± 1.8a | 1.3 ± 0.1a |
| 11           | 2.1 ± 0.1a | 2.3 ± 0.2a | 1.4 ± 0.4a | 1.2 ± 0.0a |
| 12           | 12 ± 2.2a | 5.1 ± 0.7a | 3.9 ± 0.2a | 3.8 ± 0.9a |

*Standard drug*

- Xanthorrhizol: 11 ± 0.7, 8.7 ± 0.8
- Curcumin: 4.1 ± 0.9, 8.7 ± 0.8
- Tamoxifen: 8.3 ± 0.6, 4.6 ± 0.5

DCM: Dichloromethane, GI$_{50}$ (µg/mL) is the concentration of extracts resulting in 50% reduction in cell growth in comparison with untreated cells. Values are means ± SD. For each column, values followed by the same superscript (a-d) are not statistically different at $P < 0.05$ as measured by the Tukey HSD test. HT-29 are human colon cancer cells, MCF-7 and MDA-MB-231 are human breast cancer cells, and SKOV-3 are human cervical cancer cells. GI$_{50}$ values of standard drugs of xanthorrhizol, curcumin and tamoxifen against MCF-7 and MDA-MB-231[10] were used as positive controls.

**Hoechst nuclear staining**

To examine the nuclear morphological changes in response to DCM leaf extract, which contained SA and UA, both control and treated MDA-MB-231 breast cancer cells were stained...
with fluorescent Hoechst 33342 dye and visualised under a fluorescent microscope. MDA-MB-231 cells were chosen as a candidate for apoptotic studies due to its fast doubling rate and have been demonstrated to undergo apoptosis. MDA-MB-231 cells have high invasive ability and tend to establish resistance against programmed cell death stimuli. Thus, the ability of plant extracts to arrest their proliferation is beneficial for the prevention and treatment of invasive cancer.

Results of Hoechst staining of control and treated cells showed that the dye was able to diffuse through intact membranes of the cells and stain their DNA. At 1.56, 3.13 and 6.25 µg/mL of leaf extract, the cells remained uniformly stained and showed no fluorescence in the nucleus. The cells were neither apoptotic nor exhibit fragmentation of DNA.

MDA-MB-231 cancer cells treated with higher concentrations of DCM leaf extract (12.5, 25.0 and 50.0 µg/mL) began to display apoptotic morphology [Figure 2]. As the concentration of leaf extract was increased, there was stronger and more intense fluorescence. Fluorescence was seen in the nuclear region of the cells, indicating the presence of DNA fragmentation. Cell shrinkage, chromatin condensation, nuclear fragmentation and apoptotic bodies (small highly fluorescent spherical masses) were visualised. These observations provided evidence that the DCM leaf extract had an apoptotic effect on MDA-MB-231 cells.

Caspase colorimetry
MDA-MB-231 cells were treated with varying concentrations (1.56-25.0 µg/mL) of DCM leaf extract. Fold-increase in activity of caspase-3, -6, -8 and -9 was determined by comparing the results of treated samples with the control.

Two caspases analysed showed fairly strong fold-increase activity with increasing concentration of DCM leaf extract. They were caspase-8 and -9. At 3.13 and 6.25 µg/mL of extract, caspase-8 remained at 1.50 fold. At 12.5 and 25.0 µg/mL of extract, activity increased 2.25 and 3.61 fold, respectively. Caspase-9 showed a slightly different trend of increase. At 3.13, 6.25 and 12.5 µg/mL of extract, activity strongly increased 1.64, 2.42 and 3.42 fold, respectively. Activity culminated to 3.73 fold at 25.0 µg/mL of extract. Fold-increase activity of caspase-3 was weak with caspase-6 hardly showing any activity. Caspase-3 showed no discernable activity at 3.13 and 6.25 µg/mL of extract. Activity was 1.72 and 2.33 fold at 12.5 and 25.0 µg/mL of extract. Caspase-6 showed slight decline in activity from 3.13-12.5 µg/mL of extract. Activity was only 1.31 fold at 25.0 µg/mL of extract.

Results of the caspase colorimetric assay showed that DCM leaf extract modulated caspase-8, -9 and -3 but not caspase-6, which indicates that the extract induced apoptosis through both the extrinsic (death-receptor) and intrinsic (mitochondrial) pathways. Caspase-8 and -9 are the initiator caspases, while caspase-3 and -6 are the effector caspases.

Similarly, an increase in caspase-8, -9 and -3 activities has been reported after MDA-MB-231 cancer cells were treated with 250 µM of quercetin and with 40 mM of metformin. Likewise, the induction of apoptosis of MDA-MB-231 cells involving caspase-8, -9 and -3 was also reported for sanguinarine and 2-methoxyestradiol. On the contrary, MDA-MB-231 cancer cells treated with xanthorrhizol (0-20 µg/mL) was reported to modulate caspase-3 and -9 activity but not caspase-6 and -8.

CONCLUSION
Both leaf and flower extracts of *V. glabra* showed broad-spectrum APF activity. Among the four different leaf extracts of *V. glabra*, the DCM extract showed strongest APF activity against HT-29, MCF-7, MDA-MB-231 and SKOV-3 cancer cells. The DCM extract had an apoptotic effect on MDA-MB-231 cells which involved activation of caspase-8, -9 and -3, but not caspase-6. The potential of *V. glabra* as a candidate species for anticancer drugs warrants further investigation.
