Abstract
Most insurance contracts are inherently linked to financial markets, be it via interest rates, or—as hybrid products like equity-linked life insurance and variable annuities—directly to stocks or indices. However, insurance contracts are not for trade except sometimes as surrender to the selling office. This excludes the situation of arbitrage by buying and selling insurance contracts at different prices. Furthermore, the insurer uses private information on top of the publicly available one about financial markets. This paper provides a study of the consistency of insurance contracts in connection with trades in the financial market with explicit mention of the information involved.

By defining strategies on an insurance portfolio and combining them with financial trading strategies, we arrive at the notion of insurance–finance arbitrage (IFA). In analogy to the classical fundamental theorem of asset pricing, we give a fundamental theorem on the absence of IFA, leading to the existence of an insurance–finance-consistent probability. In addition, we study when this probability gives the expected discounted cash-flows required by the EIOPA best estimate. The generality of our approach allows to incorporate many important aspects, like mortality risk or...

1 | INTRODUCTION

An insurance contract and a financial asset both qualify as securities, defined as the legal representation of the right to receive prospective future benefits under stated conditions (Sharpe et al., 1999). But an insurance contract differs substantially from a financial security since it can be sold only by a regulated office to an individual appearing explicitly in the contract (see, for example, Boudreault & Renaud, 2019). In general, the owner cannot resell the contract (with some exceptions of surrender possibilities in life insurance). He can not benefit from simultaneously high and low prices (premium) for the same contract as in arbitrage facilities in financial markets (Sharpe et al., 1999). On the other hand, the insurer might have arbitrage occasions by combining selling of contracts and trading in the market. In this case, a novel version of the arbitrage property has to be defined, which should at the same time incorporate the pooling principle as the fundamental tool in insurance.

It is a central observation that nowadays insurance contracts are often inherently and systematically linked to financial markets, be it via interest rates, or via direct links of the contractual benefits to stocks or indices (see Dhaene et al., 2013). The associated risk can be mitigated by trading on financial markets. Therefore, we have to blend finance and insurance notions. On the insurance side, no rebalancing takes place and insurance companies generally form a large portfolio of homogeneous contracts for pooling and reducing risks. These considerations have to be taken into account by a generalization of the existing notion of arbitrage in a financial market.

Another crucial difference between finance and insurance is the necessity of enlarging the filtration about macroeconomic data (including market prices as well as globally available information for insurance firms like mortality tables) with privately held information on the population of the individual policyholders.

The mentioned differences prevent a simple transfer of arbitrage to the insurance situation and we propose a new concept of an insurance–finance arbitrage (IFA). Formally, it is natural to express the arbitrage of insurance flows including those of financial trading, by looking at a with-probability-one event resulting in a net gain. This is the first point of the paper.

The apotheosis of mathematical finance is its fundamental theorem of asset pricing (FTAP) where, assuming no financial arbitrage, discounted prices of traded securities, given out of the blue, are explained as expectations. In discrete time, it is known as the Dalang–Morton–Willinger Theorem (see Dalang et al., 1990, Schachermayer, 1992, Carassus et al., 2001, Delbaen & Schachermayer, 2006, Kabanov & Stricker, 2006, to mention only few). Under the necessary extension
adapted to the insurance situation we provide—as first main result—the corresponding Theorem 3.2. To the best of our knowledge, it is the first time that the pooling method in insurance is coupled in with the financial no-arbitrage principle in such a way. On the one side, absence of IFA implies the existence of an equivalent probability measure which, restricted to the financial market, is a martingale measure, and satisfies a super-martingale inequality on the insurance side. We call such a measure insurance–finance-consistent. The super-martingale property resembles naturally the FTAP under short sales prohibition (see Pulido, 2014). On the other side, the fact that the possibility of an IFA involves two different kinds of strategies—the market trading and the selling of insurance contracts—has the consequence that the mere existence of an equivalent supermartingale measure is not sufficient to ensure absence of IFA; bounded insurance portfolio strategies together with an additional condition (Assumption 3.1) are needed to do so.

In contrast to the classical situation on financial markets where finance-consistent (or risk neutral) probabilities are used to evaluate contingent claims, a general insurance–finance-consistent measure is of no great use for the insurance company since it lacks the connection to the insurance’s statistical data. Assumption 3.1 ensures that the statistical probability $P$ is reflected in a suitable way. As a consequence, we arrive at a class of measures, which combine a martingale measure $Q$ on the market filtration with the statistical probability $P$ derived from insurance’s internal information. This construction will be called the QP-rule. The same construction already appears in Plachky and Rüschendorf (1984), studying measure extensions in a statistical context. The same problem arises in the context of time-consistent dynamic risk measures, see for example Cheridito et al. (2006). Already Dybvig (1992a) proposed to use this tool for the evaluation of nontraded wealth in the framework of state-price densities. It also appears in Pelsser and Stadje (2014) in the case where linear rules are used for valuation.

In our opinion, the measure $Q \otimes P$ is the one to be used to compute the best estimate of liabilities (BEL), legally imposed by the European Insurance and Occupational Pensions Authority (EIOPA). The presence of a risk-neutral measure $Q$ ensures moreover that the computed BEL is market consistent. However, with respect to EIOPA’s supervision rules, we only looked at the first step of insurance solvency regulation, that is, at the linear case. The following nonlinear ones, like the risk margin (RM) and the solvency capital requirement (SCR), are left for future research.

The intertwining of the two measures $Q$ and $P$ in the QP-rule makes direct calculations difficult, in particular, when it comes to determine the insurance–finance consistency of it. A sufficient condition for IFA is given in our second result, Theorem 5.1. In a slightly different setting, Corollary 5.2 yields a sufficient and a necessary condition for the insurance–finance consistency of the QP-rule.

Since our setting is very general, we are able to pass existing approaches: first, we consider a financial market without restricting to the complete case; second, we allow for arbitrary dependence between the financial market and the insurance quantities—this is important in many insurance products, for example, when considering surrender behavior or stochastic mortality. Paradigmatically, the encountered pandemic highlights the necessity of allowing dependence between mortality and stock markets; third, we do not exclude financial arbitrage when trading was done with strategies adapted to the enlarged filtration but we restrict the insurance’s hedging to strategies corresponding to the law against insider trading. Moreover, the insurance benefits need not to be bounded, as is often required when dealing with risk measures (see Artzner et al., 1999, Riedel, 2004, Cheridito et al., 2006). However, when classifying arbitrage possibilities, we distinguish between unbounded and bounded portfolio strategies (see Definition 2.4).

Finally, we exemplify the insurance–finance consistency of the QP-rule by a tractable result for a variable annuity contract whose benefits depend on the events of death and surrender. These
random times produce events which give rise to a progressive enlargement of the initial filtration and, nevertheless, can be evaluated by a nice formula.

The linkage between insurance contracts and financial markets is a problem, which has been intensively studied in the literature, see for example, Malamud et al. (2008) or Møller (2002) and references therein. The approaches, which are mostly of the partial equilibrium type, can be divided into four classes. First, quite popular is the direct application of an ad hoc chosen finance consistent (or risk-neutral) measure, see for example, Brennan and Schwartz (1976), Dai et al. (2008), Krayzler et al. (2016), Cui et al. (2017), and the references therein. It often leads to explicit results in a direct matter. Second, the benchmark approach, applied to financial markets in Platen (2006) and to the present problem in Bühlmann and Platen (2003), uses the growth-optimal portfolio as numéraire and evaluates risky products by expectations under $P$. For an insurance application see, for example, Biagini et al. (2015). In the local risk-minimization approach, third, where the risk-neutral measure on the insurance side is specified by a risk-minimizing procedure (see for example Föllmer & Schweizer, 1989; Møller, 2001; Pansera, 2012) it is assumed that insurance risks, like mortality risk, can be diversified away. This approach can be generalized to the quadratic hedging error. Finally, indifference pricing leads to a nonlinear pricing rule and we refer to Blanchet-Scalliet et al. (2015), Chevalier et al. (2016) for details and further literature. Nonlinear methods to analyze insurance contracts often use the axiomatic approach to risk measures on $L^\infty$ with the Fatou property and thus admitting robust presentations, see Tsanakas and Desli (2005); Barigou et al. (2019); Engsner et al. (2020) while this can also be treated on more general spaces, as for example, in Kaina and Rüschendorf (2009), Cheridito and Li (2009).

Our work with the QP-rule and the BEL approach can be seen as an application of the “two-step market evaluation” in Pelsser and Stadje (2014) in the sense that first we start by conditioning with respect to financial events (see also Barigou et al., 2023). Second, we use the two same integrations with respect to conditioning and to risk neutral probability, as far as the integrand is a linear form of the contract. Of course, since we fix the statistical probability $P$, the QP-rule is time- and finance-consistent as proposed in Pelsser and Stadje (2014). (For time-consistency one might also have a look to Dybvig, 1992b, Cheridito et al., 2006, Delbaen, 2006, Cheridito & Kupper, 2011, Pelsser & Ghalehjooghi, 2016). The cited authors work with nonlinear actuarial principles preventing them to obtain BEL, because of the EIOPA requirement that no prudential margin should appear in the BEL (see www.actuaries.org.uk Solvency II-2016.pdf 2.2.1 and Swiss Solvency Test Technisches Dokument 3.2). As for us, we follow this request and postpone the definitions of provision and solvency capital to a future paper, meaning that we start a different route beginning with the search of the best estimate. It will involve the two probability measures $P$ (historical probability) and $Q$ (useful for market consistency) defined on two different sigma-algebras, the private and the public information at final date. Since long, the insurance industry has gone further, beginning with BEL (but without clear mention of the probability being used) and adding RM, solvency capital, and so forth. In complementing our work, we shall introduce the objectives of shareholders, insurance seekers, and the regulator (see Albrecher et al., 2022). From this point of view, we shall look at industry’s linear best estimates, regulatory RM and capital requirement.

The approach in Chen et al. (2020) introduces a concept of valuation, called fair, if it is market consistent and in addition coincided with valuation under $P$ for payoffs, which are independent of the future stock evolution (called $t$-orthogonal). The QP-rule satisfies also this property. Hedging techniques are applied to it.

In Deelstra et al. (2020), a three-step method for the valuation of hybrid insurance products is proposed consisting at first of hedging the inherent financial risk and of diversification via pooling, and for the leftover to apply a nonlinear premium principle. The authors use an enlargement
of filtration approach with conditionally independent extensions, thus satisfying the immersion property (see Blanchet-Scalliet & Jeanblanc, 2020).

Some insurance products we have in mind are variable annuities, which explicitly link the insurance benefits to the performance of financial markets. We refer to Bacinello et al. (2011) for an extensive overview of related literature.

The paper is organized as follows: Section 2 presents the economic environment of an insurance company, containing the financial market, the insurance contracts, and their allocation portfolios. It contains the different filtrations reflecting the different states of information an insurer is acting on. Given the exogenous premiums of the standard contracts, the notion of an IFA is defined. The general fundamental theorem on non-IFA is presented in Section 3. Section 4 studies linear valuation rules for insurance claims and introduces the so-called QP-rule. This rule combines risk neutral pricing (under $Q$) with insurance evaluation (under $P$). In Section 5, we provide the second main theorem where a sufficient and a necessary condition for the insurance–finance consistency of the QP-rule are given. An example of a variable annuity contract in Section 6 underpins this property.

2 | INSURANCE AND FINANCE

Fundamental valuation principles are based on the absence of arbitrage with trading strategies as the central concept. In the case considered here, strategies incorporate trading on the financial market and selling of insurance contracts.

The well-known concept of a financial arbitrage is a self-financing trading strategy leading to a risk-less profit. On the insurance side, the portfolio consists of allocations of insurance contracts: the insurer has the possibility to sell standardized contracts for a large number of clients leading to a substantial reduction of risk. If this risk reduction—in combination with trading on a financial market—allows for a risk-less profit, we call the common portfolio an IFA. Here, we have to keep in mind that the insurer has a different status of information than the public one of the market.

On a probability space $(\Omega, \mathcal{H}, P)$ and a discrete finite time interval $\mathbb{T} = \{0, 1, \ldots, T\}$, we assume that the publicly available information (life-tables, information on financial markets, etc.) is captured by the filtration $\mathcal{F} = (\mathcal{F}_t)_{t \in \mathbb{T}}$. The insurance company has additional internal information (e.g., survival times or health states concerning the population of possible clients together with historical information). This information is encoded in the filtration $\mathcal{H} = (\mathcal{H}_t)_{t \in \mathbb{T}}$, which encompasses public information, that is,

$$\mathcal{F}_t \subset \mathcal{H}_t \quad \text{for } t = 0, \ldots, T.$$

For our model description, we start reminding the well-known concept of a financial market.

2.1 | The financial market

The financial market consists of $d + 1$ tradeable securities with $\mathcal{F}$-adapted price process $\tilde{S} = (\tilde{S}^0, \tilde{S}^1, \ldots, \tilde{S}^d)$. Traded assets could be bonds with and without credit risk, stocks, indices, and so forth. The information $\mathcal{F}$ will typically be strictly larger than the filtration generated by the traded assets: economic variables like employment rates or national mortality rates are examples of such publicly available information.

The numéraire $\tilde{S}^0$ with $\tilde{S}^0_0 = 1$ may be random, but is assumed to be strictly positive. Discounted price processes are denoted by $S = (S^1, \ldots, S^d)$ where $S^j = \tilde{S}^j / \tilde{S}^0$, $j = 1, \ldots, d$, and $S^0 \equiv 1$. 
An $\mathbb{F}$-trading strategy on the financial market is a $d$-dimensional, $\mathbb{F}$-adapted process $\xi = (\xi_t)_{0 \leq t \leq T-1}$ with $\xi_t = (\xi^1_t, \ldots, \xi^d_t)$. Note that the insurance company has access to more information than captured by $\mathbb{F}$, such that at a later point we will consider trading strategies, which are not adapted to $\mathbb{F}$ but to a larger filtration, see Section 2.4.

For a trading strategy $\xi$ (see for example Föllmer & Schied, 2016, Proposition 5.7), its (discounted) value is given by

$$V^F(\xi) := (\xi \cdot S)_T = \sum_{t=0}^{T-1} \sum_{j=1}^d \xi^j_t \Delta S^j_t,$$

with $\Delta S_t = S_{t+1} - S_t$. We assume throughout that the financial market does not allow for arbitrage so that the set $\mathcal{M}_{e,b}(S, \mathbb{F})$ of equivalent martingale (or market-consistent) measures with bounded densities under which the process $S$ is a martingale on the filtration $\mathbb{F}$, is not empty:

$$\mathcal{M}_{e,b}(S, \mathbb{F}) \neq \emptyset. \quad (1)$$

### 2.2 The insurer’s standard contracts

We assume that there is a single insurer who can contract with possibly infinitely many insurance seekers. At each date $t \in \{0, \ldots, T-1\}$, the insurer may issue contracts of one standard type$^1$, depending on $t$. Such a contract offers coverage of a future claim in exchange with a premium paid at initiation of the contract. Without loss of generality, we assume that all claims are settled at the final date $T$.

The benefits of the standard contract issued at date $t$ are described by a $\mathcal{H}_T$-measurable non-negative random variable $X_{t,T}$ (already discounted). We summarize the benefits by the process $X = (X_{t,T})_{t \in \{0, \ldots, T-1\}}$.

The candidate premium of the standard contract $X_{t,T}$ issued at $t$ is denoted by $p_t(X)$ or simply $p_t$ (already discounted); it is to be paid at date $t$ and is $\mathcal{H}_t$-measurable. The value $p_t$ has to be regarded as a basic part of premium. On top, the insurance company adds a commercial part which contains additional costs, RM’s, and so forth. RM’s are enforced by regulation and are nonlinear rules. We will treat them in future research.

For the premiums $p_t$, we assume

$$p_t \in L^1_+(\mathcal{H}_t) = L^1_+(\Omega, \mathcal{H}_t, P) \quad (2)$$

and summarize them by the process $p = (p_t)_{t \in \{0, \ldots, T-1\}}$.

### 2.3 Insurance allocations

The classical insurance principle of diversification to substantially reduce risk consists in the possibility of the insurer to issue individual independent contracts with clients, called insurance

---

$^1$The results of this paper can easily be extended to the case where contracts are offered for a finite number of different cohorts of clients. Mathematically, this amounts to simply adding an additional index for the cohorts.
Similarly, we shall assume that at each date \( t < T \) the insurer can contract with possibly infinitely many insurance seekers. The associated \( \mathcal{H}_T \)-measurable benefits of the individual contracts are denoted by \( X_{1,T}^1, X_{1,T}^2, \ldots \).

Inspired by large financial markets (e.g., Klein, 2000; Kabanov & Kramkov, 1995; Klein et al., 2016), we model the insurance portfolio as a sequence of allocations of contracts with insurance seekers: the allocation \( \psi_t = (\psi_t^i)_{i \geq 1} \) at date \( t \) is a \( \mathcal{H}_t \)-measurable, non-negative random sequence, that is, \( \psi_t^i \) denotes the size of the contract with the \( i \)th insurance seeker at date \( t \). The (discounted) value of the allocation amounts to the accumulated premiums minus the benefits over all time instances \( t = 0, \ldots, T - 1 \). More precisely, we refer to

\[
V^I(\psi) := \sum_{t=0}^{T-1} \sum_{i \geq 1} \psi_t^i \left( p_t - X_{t,T}^i \right)
\]

as the individual insurance value and to \( V^F(\xi) \) as the global financial outcome.

Finally, an insurance portfolio strategy is a double sequence \( \psi := (\psi^n_t)_{n \geq 1, 0 \leq t < T} \) of allocations. We impose the following admissibility condition for a portfolio strategy: Convergence of the insurance volume: there exist random variables \( \gamma_t \geq 0, 0 \leq t < T \) so that

\[
\| \psi^n_t \| := \sum_{i \geq 1} \psi^n_{t,i} \to \gamma_t \quad \text{a.s. for all } t < T.
\]

The precise measurability of \( \gamma_t \) is explained in the next subsection. Later, we are interested in the particular case of a bounded portfolio strategy (see Remark 2.6): in addition to Equation (4) we say that the portfolio strategy \( \psi \) is bounded if there exists \( c > 0 \) so that

\[
\| \psi^n_t \| \leq c.
\]

for all \( n \geq 1 \) and \( 0 \leq t < T \).

2.4 | Trading strategies of the insurer

We emphasize that we do not assume completeness of the financial market \((\mathcal{F}, S)\) nor do we exclude (financial) arbitrages when trading would be done with the filtration \( \mathcal{H} \), where in particular information of individual insurance contracts enters (see Remark 2.3). This information would in general allow for insider-trading, an action prohibited by law. On the other hand, it is obvious that the financial investments of an insurer depend on the global insurance-related information, which we call macro-insurance information, to distinguish them from the individual or micro-insurance information. The sales volumes of the contracts are of course macro-insurance data.

To handle this insurer’s dilemma, we assume that at date \( t \), the trading investment of the insurer are based on the information containing \( \mathcal{F}_t \) and the macro-insurance data. More precisely, we consider an intermediary filtration \( \mathcal{G} = (\mathcal{G}_t)_{t \in \mathbb{T}} \) with

\[
\mathcal{F}_t \subset \mathcal{G}_t \subset \mathcal{H}_t, \quad t \in \mathbb{T}.
\]
With this filtration at hand we assume that the process $\gamma$ from Equation (4) is $\mathcal{G}$-adapted. Moreover, the insurer is allowed to trade on the financial market with filtration $\mathcal{G}$, that is, the trading strategy $\xi$ is $\mathcal{G}$-adapted. For $t = T$, we set $\mathcal{G}_T = \mathcal{G}_{T-1} \vee \mathcal{F}_T$.

**Remark 2.1.** In the following, we do not exclude a priori that there may be arbitrage opportunities when trading with $\mathcal{G}$-adapted strategies $\xi$, that is, it may very well happen that $\mathcal{M}_{\epsilon, b}(S, \mathcal{G}) = \emptyset$. But, since $\mathcal{M}_{\epsilon, b}(S, \mathcal{F}) \neq \emptyset$, arbitrage opportunities are only possible with the additional insider knowledge on $\mathcal{G}$. We remind that in many countries, there exist laws against *insider-trading* and in addition special announcement regulations for managers when dealing with the stocks of their proper company.

The possibility of insider-trading using information about an individual customer is plausible. Let the portfolio contain an important personality, say customer $i = 1$, and let $\tau_1$ denote the beginning of a severe illness of customer 1, then the knowledge of $\tau_1 = 1$ may allow for an arbitrage possibility, for example, by trading derivatives on a stock related to the activity of customer 1.

### 2.5 From micro- to macro-insurance data

The basic principle of an insurance company is the possibility to contract with a large number of insurance seekers, which diversifies the individual risks. For the individual insurance benefits $X_{i, T}$, we generalize the classical framework of actuarial mathematics to the following conditional case. It integrates in particular the future development of the financial market and thus allows hedging parts of the insurance risks by means of trading on the financial market.

It turns out that the $\sigma$-algebra

$$\mathcal{H}_{i, T} : = \mathcal{H}_i \vee \mathcal{G}_T \quad (7)$$

containing the insurance information up to date $t$ and all the macro-insurance data $\mathcal{G}_T$ (including the publicly available information $\mathcal{F}_T$) plays a distinctive role. We make the following assumptions:

**Assumption 2.2.** For all $t \in \mathbb{T}$, the standard contract $X_{i, T} \in L^2(\Omega, \mathcal{H}_T, P)$ and the individual ones $X^i_{i, T}$ satisfy

(i) $X^1_{I, T}, X^2_{I, T}, \ldots \in L^2(\Omega, \mathcal{H}_T, P)$ are $\mathcal{H}_{i, T}$-conditionally independent,

(ii) $E[X^i_{I, T} | \mathcal{H}_{i, T}] = E[X_{i, T} | \mathcal{H}_{i, T}], \ i = 1, 2, \ldots$, and

(iii) $\text{Var}(X^i_{I, T} | \mathcal{H}_{i, T}) = \text{Var}(X_{i, T} | \mathcal{H}_{i, T}) < \infty, \ i = 1, 2, \ldots$.

**Remark 2.3.**

(i) The information about the individual contracts $X^i_{I, T}$ are included in $\mathcal{H}_T$ which—in addition to $\mathcal{G}_T$—must be sufficiently large to allow existence of the sequence $(X^i_{I, T})_{i \geq 1}$ of $\mathcal{H}_{i, T}$-conditionally independent random variables.

(ii) Assumption 2.2 differentiates between the information decoded by the filtration $\mathcal{G}$, and the micro-insurance information $\mathcal{H}$. Condition (i) allows for *conditional* independence, that is, the incorporation of the future evolution as well in the macro-insurance information—like the internal development of life tables, and so forth—as in the publicly
available information—like stock markets, possible successes in medicine, and so forth—
contained in $C_T$ together with past micro-insurance information due to $H_T$. For example, we
cover the case of (systemic) risk of future published research on new drugs and the insurance
company’s internal studies of possible trends in customers’ longevity. Remaining risks,
which are neither hedgeable nor diversifiable, have to be covered by a nonlinear risk measure
(see the three-step method in Deelstra et al., 2020), generally divided between the insurer and
the customer (see Eisele & Artzner, 2011).

(iii) The square-integrability in Assumption 2.2 could be relaxed. It is used in Proposition B.1
to conduct uniform integrability of the losses to get Equation (B.2). In general, however, equality
(B.2) will no longer hold. Intuitively, this means that the expectation of

$$\lim_{n \to \infty} \sum_{i \geq 1} \psi^n_i X^n_{t,T}$$

under a probability with density $L \in L^\infty(\Omega, H_{t,T}, P)$ can be strictly smaller than the right-
hand side of Equation (B.2). But in Equation (18), the reduced expectation still guarantees
$NIFA^\infty$ in Theorem 3.2.

2.6 | Insurance results

On the $\sigma$-algebra $H_{t,T}$, the conditional expectation of the net outcome of the standard contract $X_{t,T}$
issued at date $t < T$ is the $H_{t,T}$-measurable variable

$$Y_{t,T} := p_t - E_P [X_{t,T} | H_{t,T}].$$

(8)

The motivation to study the net outcome in Equation (8) is the following: Assume that at date $t$, the
individual contracts $(X^n_{i,t,T})_{i \geq 1}$ have been sold to the insurance seekers with a volume $\gamma_t \in L^\infty(H_i)$,
for example via the uniform portfolio strategy

$$\psi^n_t = \gamma_t \cdot (1/n, \ldots, 1/n, 0, \ldots).$$

(9)

We call the $G$-adapted process $\gamma = (\gamma_0, \ldots, \gamma_{T-1})$ the sales volume process.

By Assumption 2.2, the conditional strong law of large numbers in Majerek et al. (2005)$^2$ gives
for such an allocation

$$\lim_{n \to \infty} \sum_{i \geq 1} \psi^n_i (p_t - X^n_{i,t,T}) = \gamma_t \left( p_t - E [X_{t,T} | H_{t,T}] \right) = \gamma_t Y_{t,T}$$

(10)

and the outcome of this strategy of a large pool is given in terms of $Y_{t,T}$. The global insurance
outcome is

$$V^I(\gamma) = \sum_{0 \leq t < T} \gamma_t Y_{t,T}$$

(11)

$^2$A close look to the proof of Theorem 3.5 in Majerek et al. (2005) shows that one can give general conditions on the
allocations $psi^n_t$ implying Equation (10). In particular, one must exclude the domination of a single contract, meaning that
$\psi^{n,i} / \| \psi^n \| \to 0$ for all $t$ and all $i$. 

An insurance–finance strategy is now the pair \((\psi, \xi)\), which achieves the (discounted) insurance–finance value

\[
\lim_{n \to \infty} V^I(\psi^n) + V^F(\xi) = \sum_{0 \leq t < T} (\gamma_t Y_{t,T} + \xi_t \cdot \Delta S_t).
\]  

(12)

2.7 Insurance–finance arbitrage

The insurance–finance market is given by the triplet \((X, p, S)\), which describes the following constituents of the markets: the benefits \(X\), the candidate premiums \(p\), and the financial securities prices \(S\) with the mentioned assumptions.

**Definition 2.4.** On \((X, p, S)\), we say that an admissible insurance portfolio strategy \((\psi^n)_{n \geq 1}\), and an insurer’s trading strategy \(\xi\) form an IFA, if

\[
\lim_{n \to \infty} V^I(\psi^n) + V^F(\xi) \in L^+_0 \setminus \{0\}.
\]  

(13)

If the portfolio strategy \((\psi^n)_{n \geq 1}\) is bounded, we call \(((\psi^n)_{n \geq 1}, \xi)\) a bounded IFA, otherwise we speak of a general IFA.

If there is no general IFA on the insurance–finance market, we say no general insurance–finance arbitrage (NIFA\(^0\)) holds. If there is no bounded IFA, we say NIFA\(^\infty\) holds.

Obviously, NIFA\(^0\) implies NIFA\(^\infty\). But the converse is not true, as the following example shows:

**Example 2.5.** Let \(\Omega = \{\omega_1, \omega_2\} \times [0,1)\) with the two \(\sigma\)-algebras

\[
\mathcal{F}_0 := \emptyset, \{\omega_1, \omega_2\}\} \times \mathcal{B}([0,1)) \quad \text{and} \quad \mathcal{F}_1 := \sigma(\{\omega_1\}, \{\omega_2\}) \times \mathcal{B}([0,1))
\]

where \(\mathcal{B}([0,1))\) are the Borel-sets of [0,1). The probability is \(P(\omega \times dz) = \frac{1}{2} (\delta_{\omega_1} + \delta_{\omega_2})(\omega) \cdot dz\) with the Lebesgue-measure \(dz\) on [0,1). As the tradeable assets we take

\[
\Delta S^1_0(\omega, z) := \begin{cases} -1, & \text{if } \omega = \omega_1, \\ 1, & \text{if } \omega = \omega_2, \end{cases} \quad \text{and} \quad \Delta S^2_0(\omega, z) := \begin{cases} \frac{1}{1-z}, & \text{if } \omega = \omega_1, \\ 1 - \frac{1}{1-z}, & \text{if } \omega = \omega_2. \end{cases}
\]

The strategies

\[
\xi^1_0 = \frac{1}{1-z} \quad \text{and} \quad \xi^2_0 = 1
\]

yield the arbitrage result:

\[
\xi^1_0 \cdot \Delta S^1_0 + \xi^2_0 \cdot \Delta S^2_0 = \begin{cases} 0, & \text{if } \omega = \omega_1, \\ 1, & \text{if } \omega = \omega_2, \end{cases}
\]

while it is easy to see that there is no arbitrage with bounded strategies. But note that neither \(\xi^1_0 \cdot \Delta S^1_0\) nor \(\xi^2_0 \cdot \Delta S^2_0\) are integrable with respect to \(P\). \(\diamond\)
Remark 2.6 (On the necessity of considering bounded strategies).

(i) The reason to introduce two different notions of no-arbitrage stems from the following fact: The implication that if an “arbitrage prohibiting” probability exists, then the “no-arbitrage” condition holds, needs an extra integrability condition of the outcome of the strategy. In our case, this leads to bounded portfolio strategies. The classical trick to overcome this difficulty was already observed in Dalang et al. (1990), Remark 3.4—namely one can always change to a measure $P'$ by a bounded density where integrability holds. In the presence of infinitely many assets, this is no longer possible and we will exploit this fact explicitly by specifying uniform insurance trading strategies, which converge to the $P$-(conditional) expectation of insurance claims.

(ii) Bounded insurance strategies were first studied in Carassus et al. (2001) where the set of admissible strategies forms a closed convex cone.

In the setting considered here with two assets on different filtrations, many subtleties arise and one can not proceed as usual for the proof of a fundamental theorem. This was already observed in Kabanov and Stricker (2006); Cuchiero et al. (2020). In particular, there might be examples of two-period arbitrage.

Example 2.7. Inspired by Kabanov and Stricker (2006), we construct a two-period model containing a random set $A$ with $P(A) \in (0,1)$ and a sequence $(A_i)_{i \geq 1}$ of conditionally independent sets satisfying

$$E[\mathbb{1}_{A_i} | \sigma(A)] = \mathbb{1}_{A}.$$ 

We set $\mathcal{F}_0 = \mathcal{G}_0 = \mathcal{H}_0 = \mathcal{F}_1 = \mathcal{G}_1 = \{\emptyset, \Omega\}$, $\mathcal{F}_2 = \mathcal{G}_2 = \sigma(A)$, $\mathcal{H}_1 = \sigma((A_i)_{i \geq 1})$, and $\mathcal{H}_2 = \sigma(A, (A_i)_{i \geq 1})$ such that $\mathcal{H}_{0,2} = \mathcal{F}_2$. A possible interpretation is as follows: Let $A_i$ be the outbreak of an epidemic illness of the individual customer $i$. At date $t = 1$, these individual outbreaks are known to the insurer, but the general event $A$ is known publicly only at date $t = 2$.

The insurance contracts are

$$X^i_{0,2} = 3/2 \mathbb{1}_{A_i} \quad \text{and} \quad X^i_{1,2} = 0,$$

together with the standard strategy $\psi^n_0 = (1/n, \ldots, 1/n, 0 \ldots)$ and a premium $p_0 = 1$ so that

$$Y_{0,2} = p_0 - E[X^i_{0,2} | \mathcal{H}_{0,2}] = \mathbb{1}_{A^c} - 1/2 \mathbb{1}_{A}.$$ 

For the financial market, we take

$$S_0 = S_1 = 1 \quad \text{and} \quad S_2 = 2 \mathbb{1}_A + 1/2 \mathbb{1}_{A^c} \quad \text{so that} \quad \Delta S_1 = \mathbb{1}_A - 1/2 \mathbb{1}_{A^c}.$$ 

With the financial strategies $\xi_0 = 0$ and $\xi_1 = 1$, we find that

$$\lim_{n \to \infty} V^I(\psi^n) + V^F(\xi) = 1/2,$$

an IFA. ∗
3 | THE FUNDAMENTAL THEOREM OF INSURANCE–FINANCE ARBITRAGE

In this section, we analyze the insurance–finance market and characterize when NIFA holds. Combining trading on the financial market with the net outcome on the insurance markets yields the following set of possible terminal values generated from insurance–finance trading, described by the cone $\mathcal{K}$:

$$\mathcal{K} := \left\{ \sum_{0 \leq t < T} (\gamma_t Y_{t,T} + \xi_t \Delta S_t) \mid \gamma_t \in L^0_+(\mathcal{G}_t, \mathbb{R}^1), \text{ and } \xi_t \in L^0(\mathcal{G}_t, \mathbb{R}^d) \right\}. \quad (14)$$

We note that all random variables in $\mathcal{K}$ are $\mathcal{H}_{T-1,T}$-measurable.

For the following theorem, we will also rely on a measure $P^*$ under which we will assume that Assumption 2.2 is satisfied. In addition, we will assume that the conditional expectation of $X_{t,T}$ under $P^*$ coincides with those under $P$:

**Assumption 3.1.** Consider $P^* \sim P$ and assume that for all $t \in \mathbb{T}$,

(i) $X^1_{t,T}, X^2_{t,T}, \ldots \in L^2(\Omega, \mathcal{H}_{t,T}, P^*)$ are $\mathcal{H}_{t,T}$-conditionally independent under $P^*$,

(ii) $E_{P^*} [X^i_{t,T} | \mathcal{H}_{t,T}] = E_{P^*} [X^1_{t,T} | \mathcal{H}_{t,T}]$, $i = 2, 3, \ldots$ and

(iii) $\text{Var}_{P^*}(X^1_{t,T} | \mathcal{H}_{t,T}) = \text{Var}_{P^*}(X^1_{t,T} | \mathcal{H}_{t,T}) < \infty$, $i = 2, 3, \ldots$.

We can now formulate our main result.

**Theorem 3.2.** On the insurance–finance market $(X, p, S)$ with Assumption 2.2, the sequence of implications $(i) \Rightarrow (ii) \Rightarrow (iii)$ holds for the following assertions:

(i) $\text{NIFA}_0$ holds.

(ii) $(\mathcal{K} - L^0_+(\mathcal{H}_{T-1,T})) \cap L^0_+(\mathcal{H}_{T-1,T}) = \{0\}$.

(iii) There exists $P^* \sim P$ on $(\Omega, \mathcal{H}_{T-1,T})$ so that

(iii.a) $P^* | _{\mathcal{G}_T} \in \mathcal{M}_{e,b}(S, \mathcal{G})$ and

(iii.b) $E_{P^*}[Y_{t,T} | \mathcal{G}_t] \leq 0$ for $t = 0, \ldots, T - 1$.

Moreover, if Equation (iii) holds and $P^*$ satisfies Assumption 3.1, then

(iv) $\text{NIFA}_\infty$ holds.

**Proof.** We begin by showing $(i) \Rightarrow (ii)$. Assume that we have

$$\gamma \cdot Y + \xi \cdot \Delta S = \sum_{t=0}^{T-1} \gamma_t \left( p_t - E[X_{t,T} | \mathcal{H}_{t,T}] \right) + \xi \cdot \Delta S \in L^0_+(\mathcal{H}_{T-1,T}) \setminus \{0\}. \quad (15)$$

We first consider the uniform portfolio strategy with the volume $\gamma_t$:

$$\phi^u_t = \gamma_t \cdot (1/n, \ldots, 1/n, 0 \ldots).$$
By Assumption 2.2, Theorem 3.5 of the conditional strong law of large numbers in Majerek et al. (2005) gives for such an allocation the following result:

\[
\lim_{n \to \infty} \sum_{i \geq 1} \psi_{i}^{n} \left( p_{t} - X_{i,T}^{i} \right) = \gamma_{t} \left( p_{t} - E \left[ X_{i,T} \mid \mathcal{H}_{t,T} \right] \right) =: \gamma_{t} Y_{t,T}.
\]

Therefore, Equation (15) yields

\[
\lim_{n \to \infty} V^{I}(\psi^{n}) + V^{F}(\xi) = \gamma_{t} Y_{t,T} + \xi \cdot \Delta S \in L_{+}^{0} \left( \mathcal{H}_{T-1,T} \right) \setminus \{0\}
\]
a contradiction to NIFA\textsuperscript{0}. This shows Equation (i) ⇒ (ii).

Next, we show Equation (ii) ⇒ (iii). Changing \( P \) by a suitable bounded strictly positive density to some \( P_{1} \) allows to assume \( Y_{t,T} \) and \( \Delta S_{t} \) in \( L^{1}(\mathcal{H}_{T}) \). By Proposition A.3 also \( \mathcal{K} \cap L^{1}(\mathcal{H}_{T-1,T}) \) is closed in \( L^{1}(\mathcal{H}_{T-1,T}) \). The Kreps–Yan theorem gives another bounded strictly positive density, leading to the probability \( P^{*} \) so that

\[
E_{P^{*}}[\mathbbm{1}_{A_{t}} Y_{t,T}] \leq 0,
\]

for all \( A_{t} \in \mathcal{G}_{t} \), which shows Equation (iii.a). Similarly, we get \( E_{P^{*}}[\mathbbm{1}_{A_{t}} Y_{t,T}] \leq 0 \), which shows Equation (iii.b) of the theorem.

With Proposition B.2, we prove the final implication of Theorem 3.2. Let \( P^{*} \) be an equivalent probability measure on \( (\Omega, \mathcal{H}_{T-1,T}) \) with density \( L = dP^{*}/dP \) bounded by \( C \) and satisfying Equations (iii.a) and (iii.b). Further, assume that we had a bounded IFA, that is,

\[
\lim_{n \to \infty} V^{I}(\psi^{n}) + V^{F}(\xi) \in L_{0}^{+} \setminus \{0\}
\]

for some bounded portfolio strategy \( (\psi^{n})_{n \geq 1} = (\psi_{i}^{n})_{n \geq 1, i < T} \) and some financial strategy \( (\xi_{t})_{t \leq T} \).

First, \( \lim_{n \to \infty} V^{I}(\psi^{n}) + V^{F}(\xi) \geq 0 \) implies with Equation (5) that

\[
V^{F}(\xi) \geq - \lim_{n \to \infty} V^{I}(\psi^{n}) \geq - \sum_{t=0}^{T-1} \lim_{n \to \infty} \sum_{i \geq 1} \psi_{i}^{n} p_{t} \geq - c \sum_{t=0}^{T-1} p_{t}.
\]

Since Equation (2) implies that \( E_{P^{*}}[p_{t}] = E_{P}[L \cdot p_{t}] \leq C E_{P}[p_{t}] < \infty \), for \( t = 0, \ldots, T-1 \), it follows that \( E_{P^{*}}[V_{T}(\xi)^{-}] < \infty \) and we obtain

\[
E_{P^{*}}[V^{F}(\xi)] = 0.
\]

This property yields

\[
E_{P^{*}} \left[ \lim_{n \to \infty} V^{I}(\psi^{n}) + V^{F}(\xi) \right] = E_{P^{*}} \left[ \lim_{n \to \infty} V^{I}(\psi^{n}) \right] = \sum_{t < T} E_{P^{*}} \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi_{i}^{n} \left( p_{t} - X_{i,T}^{i} \right) \right].
\]
By Equation (4) together with Proposition B.2,

\[
(18) = \sum_{t < T} E_{P^*}[\gamma_t p_t] - E_{P^*} \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi_{t_i} X_{t,T} \right]
= \sum_{t < T} E_{P^*}[\gamma_t p_t] - E_{P^*} [\gamma_t E_P[X_{t,T}|\mathcal{H}_{t,T}]].
\]

Property (iii.b) of \( P^* \) and the non-negativity of \( \gamma_t \) yields

\[
E_{P^*} [\gamma_t (p_t - E_P[X_{t,T}|\mathcal{H}_{t,T}])] = E_{P^*} [\gamma_t E_{P^*}[Y_{t,T}|\mathcal{G}_t]] \leq 0.
\]

Hence, Equation (18) is non-positive, which is a contradiction to the assumption of an IFA. The part (iii) \( \Rightarrow \) (iv) of Theorem 3.2 is proven, too. \qed

**Remark 3.3.** The work Kabanov and Stricker (2006) is the one which is most related to our work. The authors consider trading strategies, which are adapted to a reference filtration, but stock prices do not need to be adapted. In the insurance–finance case presented here, the probability \( P^* \) is characterized by two separate properties: Equation (iii.a) and (iii.b) corresponding to the two elements \( V^I \) and \( V^F \) of the insurance–finance result. Therefore, the additional boundedness condition (5) is needed.

**Remark 3.4 (On the necessity of Assumption 3.1).** Condition (iii) is not enough to imply the absence of insurance arbitrage: indeed, this is visible in (18), where the term

\[
E_{P^*} \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi_{t_i} (p_t - X_{t,T}) \right]
\]

is considered. Passing from \( X_i \) to \( X \) is possible under \( P \) by Assumption 2.2, but with an absolutely continuous change of measure, the expectation under \( P \) may be greater than zero. Assumption 3.1 allows to apply Proposition iii.b and hence puts us in the position to apply property (3.2).

### 3.1 Market consistency

In mathematical finance, the notion of a *market-consistent evaluation* was, to the best of our knowledge, first introduced by Cont (2006), Cheridito et al. (2008), Malamud et al. (2008), and Artzner and Eisele (2010). See also Pelsser and Stadje (2014), among others. This property is mainly applied to nonlinear evaluations (like risk measures) of risky situations, requiring that the evaluation acts linearly on traded positions via their market values. In our context, it would be preferable to call this property *finance-consistent*. In the linear case\(^3\), it can be naturally extended to the following notion:

---

\(^3\)The property of insurance–finance-consistent evaluations plays also an important role for nonlinear operators, like risk measures. They appear at the calculation of risk margins (RM) and solvency capital requirements (SCR) for insurance companies (see Hainaut et al., 2018). In particular, the calculation of the risk margin should be market-consistent, since
**Definition 3.5.** An equivalent probability measure $P^*$ on $(\Omega, \mathcal{G}_{T-1,T})$ is called **insurance–finance-consistent** if it satisfies the conditions (iii.a) and (iii.b) of Theorem 3.2.

Such a consistent probability measure can be used for arbitrage-free valuation in the usual sense: indeed, if $P^*$ is insurance–finance consistent and we consider the so-called **reference premium**, associated to $P^*$,

$$P^*_t = E_{P^*}[X_{t,T}|\mathcal{H}_t],$$

then conditions (iii.a) and (iii.b) of Theorem 3.2 are met and—given that $P^*$ satisfies Condition 3.1—there is no IFA with respect to the reference premium $p^*$ in the sense of $\text{NIFA}^{\infty}$.

We study a case on a finite probability space in the following example.

**Example 3.6.** We consider two points in time, $T = \{0, 1\}$, and $\Omega = \{\omega_1, \omega_2, \omega_3, \omega_4\}$ with the two filtrations $\mathcal{F} = (\mathcal{F}_0, \mathcal{F}_1)$ and $\mathcal{G} = (\mathcal{G}_0, \mathcal{G}_1)$ given by

$$\mathcal{F}_0 = \{\emptyset, \Omega\}, \quad \mathcal{F}_1 = \sigma(\{\omega_1, \omega_3\}, \{\omega_2, \omega_4\})$$

resp.

$$\mathcal{G}_0 = \sigma(\{\omega_1, \omega_2\}, \{\omega_3, \omega_4\}), \quad \mathcal{G}_1 = \mathcal{P}(\Omega).$$

Besides the constant asset $S^0 \equiv 1$, the risky asset of a financial market is $S^1_0 \equiv 1$ and $S^1_1 = \frac{3}{2} \mathbb{1}_{\{\omega_1, \omega_3\}} + \frac{1}{2} \mathbb{1}_{\{\omega_2, \omega_4\}}$ such that on the filtration $\mathcal{F}$, we have a complete market with the unique finance-consistent probability:

$$Q(\{\omega_1, \omega_3\}) = Q(\{\omega_2, \omega_4\}) = \frac{1}{2}.$$

The statistical probability $P$ is supposed to be

$$P(\{\omega\}) = 0.3 \mathbb{1}_{\{\omega_1, \omega_2\}} + 0.2 \mathbb{1}_{\{\omega_3, \omega_4\}}$$

and as such it is finance-consistent since $P(\{\omega_1, \omega_3\}) = P(\{\omega_2, \omega_4\}) = \frac{1}{2}$, that is, $P|_{\mathcal{F}_T} = Q$.

For the standard insurance contract, we assume

$$p_0 = 4 \mathbb{1}_{\{\omega_1, \omega_2\}} + 2 \mathbb{1}_{\{\omega_3, \omega_4\}}$$

$$X_{0,1} = 5 \mathbb{1}_{\{\omega_1\}} + 2 \mathbb{1}_{\{\omega_2\}} + 3 \mathbb{1}_{\{\omega_4\}}$$

such that the net outcome is

$$Y_{0,1} = p_0 - X_{0,1} = -1 \mathbb{1}_{\{\omega_1\}} + 2 \mathbb{1}_{\{\omega_2\}} + 2 \mathbb{1}_{\{\omega_3\}} - \mathbb{1}_{\{\omega_4\}}$$

Since also any insurance–finance-consistent probability $P^*$ must be finance-consistent, it is of the form

$$P^* = \frac{1}{2} (\alpha \mathbb{1}_{\{\omega_1\}} + \beta \mathbb{1}_{\{\omega_2\}} + (1 - \alpha) \mathbb{1}_{\{\omega_3\}} + (1 - \beta) \mathbb{1}_{\{\omega_4\}}).$$

in bookkeeping, it is classified as external capital and therefore should not include risk, which can be hedged by the insurance company.
with $\alpha, \beta \in (0, 1)$. This implies that

$$E_{P^*} [Y_{0,1} | \mathcal{G}_0] = \begin{cases} \frac{2^\beta - \alpha}{\alpha + \beta}, & \text{on the set } \{\omega_1, \omega_2\} \\ \frac{1 + \beta - 2 \alpha}{2 - (\alpha + \beta)}, & \text{on the set } \{\omega_3, \omega_4\}. \end{cases}$$

Hence, $P^*$ is equivalent and insurance–finance-consistent if and only if

$$\alpha > \frac{1}{2} \quad \text{and} \quad 0 < \beta \leq \min(\alpha/2, 2\alpha - 1).$$

Therefore, here the statistical probability $P$ is finance-consistent but not insurance–finance-consistent.

On the other hand, if instead of $p_0$, the premium is raised to $\tilde{p}_0 = 5 \mathbb{1}_{\{\omega_1, \omega_2\}} + 3 \mathbb{1}_{\{\omega_3, \omega_4\}}$, then obviously we have an IFA. ⋄

4 VALUATION OF NONTRADED WEALTH: THE QP-RULE AND EIOPA

Insurance companies have a sound collection of statistical data out of which they create a sufficiently reliable probability $P$ for the events they are interested in. On the other hand, insurance contracts are more and more linked to financial markets as for example in variable annuities, equity-linked life insurance, and so forth, so-called hybrid products or even directly via interest rates. These contracts, once sold, are not traded on markets. Therefore often the statistical valuation and the market valuation of the contracts do not coincide. By the FTAP, it is commonly agreed upon that market valuation should be done by a risk neutral—better called finance-consistent—probability measure (cf. Theorem 3.2). Hence a consistent valuation rule linking traded assets with nontraded insurance contracts is of highest importance. Moreover, as already mentioned before, insurance companies have more information than the publicly available information of financial markets.

Altogether we, therefore, face two measures, the statistical measure $P$ and a risk neutral one, defined on different $\sigma$-fields and are seeking a solution of the following problem: given two $\sigma$-algebras $\mathcal{F} \subset \mathcal{H}$ on a set $\Omega$, a probability $Q$ on $(\Omega, \mathcal{F})$, and a probability $P$ on $(\Omega, \mathcal{H})$, how should we extend $Q$ to $(\Omega, \mathcal{H})$ in a $P$-reasonable way. We assume that $Q$ and the restriction $P|\mathcal{F}$ of $P$ to $\mathcal{F}$ are equivalent.

We record a key concept in the area, the $Q \odot P$ probability measure, which exploits the two different properties of $P$ and $Q$, namely the statistical information and the financial market information. The first to propagate this tool were Plachky and Rüschendorf (1984), studying measure extensions in a statistical context. The same problem arises in the context of time-consistent dynamic risk measures, see, for example, Cheridito et al. (2006). Already Dybvig (1992a) proposed to use this tool for the evaluation of nontraded wealth in the framework of state-price densities. Pelsser and Stadje (2014) use this method to build a coherent risk measure with a leading probability term $Q$ in the context of actuarial premium principles.

We start by formulating the measure-extension from Plachky and Rüschendorf (1984) in a context with two filtrations. We work on a measurable space $(\Omega, \mathcal{H})$ with two filtrations $\mathcal{F} = (\mathcal{F}_t)_{t \in \mathbb{T}}$ and $\mathcal{H} = (\mathcal{H}_t)_{t \in \mathbb{T}}$ such that $\mathcal{F}_t \subset \mathcal{H}_t$ for all $t \in \mathbb{T}$. Note that the result can be extended to $T = \infty$. 
under the condition that there exists a martingale measure \( Q \) on \((\Omega, \mathcal{F}_\infty)\). For simplicity, we write \( \mathcal{F} \) and \( \mathcal{H} \) instead of \( \mathcal{F}_T \), respectively, \( \mathcal{H}_T \) in the following.

**Proposition 4.1.** There is a unique probability measure, denoted by \( Q \odot P \), on \((\Omega, \mathcal{H})\) such that \( Q \odot P = Q \) on \( \mathcal{F} \) and for all \( A \in \mathcal{H} \), it holds that \( Q \odot P(A | \mathcal{F}) = P(A | \mathcal{F}) \). This measure \( Q \odot P \) satisfies for any random variable \( X \geq 0 \) that

(i) for a \( \sigma \)-algebra \( \mathcal{G} \subset \mathcal{F} \),

\[
E_{Q \odot P}[X | \mathcal{G}] = E_Q[E_P[X | \mathcal{F}] | \mathcal{G}],
\]

(ii) for a \( \sigma \)-algebra \( \mathcal{G} \) satisfying \( \mathcal{F} \subset \mathcal{G} \subset \mathcal{H} \),

\[
E_{Q \odot P}[X | \mathcal{G}] = E_P[X | \mathcal{G}].
\]

Intuitively, the result states that \( Q \odot P \) coincides with the pricing measure \( Q \) on the information of the financial market, thus is market-consistent. From Equation (4.1), the measure \( Q \odot P \) provides: for \( t \in \mathbb{T} \), and for \( X \in L^1 \) or bounded from below:

\[
E_{Q \odot P}[X | \mathcal{F}_t] = E_Q[E_P[X | \mathcal{F}_T] | \mathcal{F}_t].
\]

**Proof.** We construct the measure \( Q \odot P \) as follows: let \( L \) denote the Radon–Nikodym derivative \( L \) of \( Q \) with respect to \( P|_{\mathcal{F}} \), such that \( dQ = L \, dP \). Define \( Q \odot P \) on \((\Omega, \mathcal{H})\) by

\[
d(Q \odot P) = L \, dP,
\]

such that \( Q \odot P(A) = E_P[1_A L] \) for \( A \in \mathcal{H} \). Obviously, \( Q \odot P \) and \( Q \) coincide on \( \mathcal{F} \) by construction. Moreover, for \( A \in \mathcal{H} \), we have that

\[
\int_B 1_A \, d(Q \odot P) = \int_B 1_A L \, dP = \int_B L \, P(A | \mathcal{F}) \, dP = \int_B P(A | \mathcal{F}) \, d(Q \odot P), \quad \text{for all } B \in \mathcal{F},
\]

such that \( Q \odot P(A | \mathcal{F}) = P(A | \mathcal{F}) \).

For uniqueness, consider a further measure \( R \), such that \( R = Q \) on \( \mathcal{F} \) and such that \( R(\cdot | \mathcal{F}) = P(\cdot | \mathcal{F}) \). Then, for \( A \in \mathcal{H} \), it holds that

\[
R(A) = \int R(A | \mathcal{F}) \, dR = \int P(A | \mathcal{F}) \, dR = \int P(A | \mathcal{F}) \, dQ = Q \odot P(A)
\]

and we obtain that \( Q \odot P = R \).

In view of Equation (4.1), we obtain with \( A \in \mathcal{H} \) that

\[
\int_B 1_A \, d(Q \odot P) = \int_B L \, P(A | \mathcal{F}) \, dP = \int_B P(A | \mathcal{F}) \, dQ \quad \text{for all } B \in \mathcal{G} \subset \mathcal{F},
\]
so that \( E_{Q \otimes P}(1_A \mid \mathcal{G}) = E_Q(P(A \mid \mathcal{F}) \mid \mathcal{G}) \) and an application of the monotone class theorem yields (4.1).

Finally, for Equation (4.1), we observe that by Bayes’ rule, it follows from \( \mathcal{F} \subset \mathcal{G} \subset \mathcal{H} \) that

\[
E_{Q \otimes P}[X \mid \mathcal{G}] = \frac{E_P[L X \mid \mathcal{G}]}{E_P[L \mid \mathcal{G}]} = \frac{L E_P[X \mid \mathcal{G}]}{L} = E_P[X \mid \mathcal{G}],
\]

since \( L \) is strictly positive a.s. and \( \mathcal{F} \)-measurable and hence \( \mathcal{G} \)-measurable. \( \square \)

Under our assumption (1) in Section 2.1 that the financial market \( (S, \mathcal{F}) \) is free of arbitrage with respect to publicly available information \( \mathcal{F} \), we have a finance-consistent measure \( Q \in \mathcal{M}_{e,b}(S, \mathcal{F}) \) on \( (\Omega, \mathcal{F}) \). We emphasize that for the formation of \( Q \), only trading strategies adapted to \( \mathcal{F} \) are used. Applying Proposition 4.1 to general values, we get a tool—called the QP-rule —to evaluate in the spirit of Dybvig (1992a) nontraded wealth in a way excluding financial arbitrage.

In combination with the probability \( P \) statistically gained by the insurer, the QP-rule yields a reference premium \( p^* \) associated to \( Q \otimes P \) for benefits \( Y \):

\[
p^* = E_{Q \otimes P}[Y].
\]  

(26)

In this case, there is no IFA if the premium \( p \) asked for the benefit \( Y \) is less than \( p^* \).

In our opinion, it is also to be used for computing the regulatory BEL required in the European Directive 2009/1388/CE Article 77: The best estimate shall correspond to the probability-weighted average of future cash-flows taking account of the time value of money (expected present value of future cash-flows using the relevant risk-free interest rate term structure). Moreover, the fact that the QP-rule is linear does agree with the regulation that no prudential margin should appear in the BEL.

**Example 4.2** (A discrete example of an hybrid insurance contract). Consider a one-period model with three states on the financial market: high, middle, and low \((h, m, l)\). We assume two cases on the insurance side: insured situation and not insured situation \((in, out)\). This corresponds to

\[
\Omega = \{(h, in), (h, out), (m, in), (m, out), (l, in), (l, out)\}.
\]

Denote the high, middle, and low states of the market by \( h = \{(h, in), (h, out)\}, m = \{(m, in), (m, out)\}, \) and \( l = \{(l, in), (l, out)\} \). Similar for the insurance cases: \( in = \{(h, in), (m, in)\}, \) and \( out = \{(h, out), (m, out)\} \). The information on the financial market is given by \( \mathcal{F} = \sigma(h, m, l) \), while \( \mathcal{G} = \mathcal{H} = \mathcal{P}(\Omega) \). Besides the constant equal to 1 numéraire, there is a risky asset \( S \) with the values \( S_0 = 1 \) and \( S_1(h) = 1.5, S_1(m) = 1, \) and \( S_1(l) = 0.5 \). Below, we shall discuss different cases of probabilities \( P \) on \( \mathcal{H} \).

We assume that the insurance offers a hybrid contract of the type:

\[
X_{0,1} = 1_{[in]} \cdot (S_1 - 0.7)^+, \]

that is, a call in the risky asset with strike price 0.7 to be paid only in the insured situation \( in \). This contract is offered at a premium \( p_0 \) and sold by a uniform portfolio strategy \( \psi^n_t = (1/n, \ldots, 1/n, 0) \). Using a financial strategy \( \xi_0 \) for the risky asset \( S \), the insurance-finance result

---

4 The probability \( Q \otimes P \) is also called pasting of \( Q \) with \( P \).
We want to apply the QP-rule to this contract and investigate when it is insurance–finance-consistent.

First, we start with a complete market by assuming that $P$ is given by the vector on $\Omega$:

$$(0.1 \alpha, 0.9 \alpha, 0, 0, 0.4 (1 - \alpha), 0.6 (1 - \alpha)).$$

with $\alpha \in (0, 1)$. The unique finance-consistent probability on $\mathcal{F}$ is $Q = \frac{1}{2} (\mathbb{1}_h + \mathbb{1}_l)$. As the conditional probability, we find

$$P(\cdot | \mathcal{F}) = \mathbb{1}_h (0.1, 0.9, 0, 0, 0, 0) + \mathbb{1}_l (0, 0, 0, 0, 0.4, 0.6),$$

independent of $\alpha$. For the QP-rule, we get $Q \odot P(\cdot) = (0.05, 0.45, 0, 0, 0.2, 0.3)$.

Hence,

$$E_{Q \odot P} \left[ \lim_{n \to \infty} V_t^I(\psi^n) + V_t^F(\xi) \right] = p_0 - 0.8 \times 0.05 = p_0 - 0.04.$$

The probability $Q \odot P$ is insurance–finance-consistent if and only if $p_0 \leq 0.04$. The risk minimizing financial strategy (in the sense of ess inf) is $\xi^* = 0.8$.

Second, we consider an incomplete market where the physical probability $P$ has the vector form

$$(0.1 \alpha, 0.9 \alpha, 0.2 \beta, 0.8 \beta, 0.4 (1 - \alpha - \beta), 0.6 (1 - \alpha - \beta)).$$

with $\alpha, \beta, 1 - \alpha - \beta \in (0, 1)$. The set of finance-consistent measures on $\mathcal{F}$ is given by $Q^\eta(h) = \eta$, $Q^\eta(m) = 1 - 2\eta$, and $Q^\eta(l) = \eta$, with $\eta \in (0, \frac{1}{2})$. The conditional probability $P(\cdot | \mathcal{F})$ is now

$$P(\cdot | \mathcal{F}) = \mathbb{1}_h (0.1, 0.9, 0, 0, 0, 0) + \mathbb{1}_m (0, 0, 0.2, 0.8, 0, 0) + \mathbb{1}_l (0, 0, 0, 0.4, 0.6),$$

and $Q^\eta \odot P$ has the vector form $(0.1 \eta, 0.9 \eta, 0.2 (1 - 2 \eta), 0.8 (1 - 2 \eta), 0.4 \eta, 0.6 \eta)$. It follows that

$$E_{Q^\eta \odot P} \left[ \lim_{n \to \infty} V_t^I(\psi^n) + V_t^F(\xi) \right] = p_0 - 0.06 + 0.04\eta.$$

Thus, if $p_0 \leq 0.04$, then all QP-rules of the form $Q^\eta \odot P$ are insurance–finance-consistent. Again, the risk minimizing financial strategy is $\xi^*_0 = 0.8$, and only if $p_0 > 0.4$, there is the possibility of IFA. This shows that even if all QP-measures are insurance–finance-consistent, it does not exhaust all cases of non-IFAs.

The reader might have noticed that we are able to deal with dependence of financial and insurance risks from the very beginning by not imposing a product structure to the probability $P$, in particular, we should be better prepared for the cases of hybrid products, which do not allow to fully disentangle the two risks. ⋇
The classification of absence of arbitrage in financial markets often utilizes the well-known no-arbitrage price bounds, given by suprema and infima over prices computed under equivalent martingale measures. In this section, we will establish similar tools in the insurance–finance context.

Recall that

\[ \mathcal{F}_t \subset \mathcal{G}_t \subset \mathcal{H}_t \quad \text{for all } t \in \mathbb{T}. \]

We define for a random variable \( \zeta \) and a \( \sigma \)-field \( \mathcal{F} \subset \mathcal{H} \)

\[
\text{ess inf}_{\mathcal{F}} \zeta := \text{ess sup}\{ \eta \in L^0(\mathcal{F}) \mid \eta \leq \zeta \}
\]

and similarly for a set of random variables instead of \( \zeta \).

The following notions reveal to be important. Let

\[
\delta_{t,T} := \text{ess inf}_{\mathcal{F}_T} \left( p_t - E_P[X_{t,T} \mid \mathcal{H}_{t,T}] \right)
\]

and for \( t < T \)

\[
\pi_t^\uparrow(\delta_{t,T}) := \text{ess sup}_{Q \in \mathcal{R}_{\mathcal{E,B}(\mathcal{F})}} E_Q[\delta_{t,T} \mid \mathcal{F}_t] \quad \text{and} \quad \pi_t^\downarrow(\delta_{t,T}) := \text{ess inf}_{Q \in \mathcal{R}_{\mathcal{E,B}(\mathcal{F})}} E_Q[\delta_{t,T} \mid \mathcal{F}_t].
\]

Our second result is the following theorem about the absence of insurance–finance consistency.

**Theorem 5.1.** Consider the insurance–finance market \( (X, p, S) \) with Assumptions 2.2. If there exists \( t < T \), so that \( \delta_{t,T} \) is bounded from above and

\[
P \left( \pi_t^\uparrow(\delta_{t,T}) > 0 \quad \text{and} \quad \pi_t^\downarrow(\delta_{t,T}) \geq 0 \right) > 0
\]

then there exists an IFA with bounded portfolio strategy and the \( Q \otimes P \) measure is not insurance–finance-consistent.

**Proof.** Assume that for one \( t < T \), we have a set \( A_t := \{\pi_t^\uparrow > 0 \quad \text{and} \quad \pi_t^\downarrow \geq 0\} \in \mathcal{F}_t \) with \( P(A_t) > 0 \). Since \( 1_{A_t} \delta_{t,T} \) is bounded from above and \( 1_{A_t} \pi_t^\downarrow(\delta_{t,T}) \) is the conditional subhedging price of \( 1_{A_t} \delta_{t,T} \), Proposition 3.14 in Niemann and Schmidt (2021) yields that there is a subhedging strategy \( \xi = 1_{A_t} \xi \) so that

\[
1_{A_t} \delta_{t,T} + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \geq 1_{A_t} \pi_t^\downarrow \geq 0.
\]

\[5\] Compare Proposition 2.6 in Barron et al. (2003).
since

on the set $A_t \cap \{\pi_t^i = \pi_t^j\}$, we have

$$\delta_{t,T} + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s = \pi_t^j > 0,$$

while on the set $A_t \cap \{\pi_t^j > \pi_t^i\}$, we get

$$\delta_{t,T} + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s > \pi_t^i \geq 0,$$

so that we conclude

$$\mathbb{1}_{A_t} \left( \delta_{t,T} + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \right) \in L^0_+ \setminus \{0\}. \quad (32)$$

At $t$ we take the uniform portfolio strategy $\psi^n_t = \mathbb{1}_{A_t} (n^{-1}, \ldots, n^{-1}, 0, \ldots)$, restricted to the set $A_t$ and $\psi^n_s = 0$ for all $s \neq t < T$. This is a bounded admissible strategy and since

$$\sum_{i \geq 1} \frac{1}{i^2} \text{Var}(X_{i,T}^j \mid \mathcal{H}_{t,T}) = \text{Var}(X_{i,T} \mid \mathcal{H}_{t,T}) \sum_{i \geq 1} \frac{1}{i^2} < \infty,$$

we are entitled to apply the conditional strong law of large numbers given in Theorem 3.5 in Majerek et al. (2005). Hence with Assumption 2.2 and the fact that $y_t = \sum_{i \geq 1} \psi^n,i = \mathbb{1}_{A_t} \in \mathcal{F}_t$, we get

$$\sum_{i \geq 1} \psi^n,i X_{i,T}^j \to \mathbb{1}_{A_t} E_P[X_{i,T} \mid \mathcal{H}_{t,T}], \quad (33)$$

$P$-almost surely as $n \to \infty$. With the subhedging strategy $\xi$ from above and the allocation $\psi_t^n$, we find

$$\lim_{n \to \infty} V_I^I(\psi_t^n) + V_I^F(\xi) = \mathbb{1}_{A_t} \left( p_t - E[X_{i,T} \mid \mathcal{H}_{t,T}] + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \right) \geq \mathbb{1}_{A_t} \left( \delta_{t,T} + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \right) \in L^0_+ \setminus \{0\}$$

by Equation (32). The existence of an IFA with bounded portfolio strategy is proved.  \qed

The fact that there exists in general a gap between the insurance–finance-consistency of all $Q \circ P$-measures and the possibility of an IFA was already shown in Example 4.2. The reason for this is that the martingale property implied by absence of arbitrage on the financial assets allows for arbitrary equivalent changes of measures on nontraded assets, like the insurance quantities considered here and, therefore, provides only weak guidance towards efficient pricing. The QP-rule, however, links the pricing of nontraded wealth to the statistical measure $P$ and, therefore, produces more reasonable prices.
Now, we make the additional assumption—interesting in itself—that the insurer is not able to exploit arbitrage on the financial market by the information contained in $\mathcal{G}$, that is,

$$\mathcal{M}_{e,b}(S, G) \neq \emptyset. \quad (34)$$

Note that if $Q \in \mathcal{M}_{e,b}(S, G)$, then the QP-measure $Q \otimes P$ inherits the Assumption 3.1 from the measure $P$.

**Corollary 5.2.** Assume that Equation (34) holds and consider the insurance–finance market $(X, p, S)$ with Assumption 2.2. Then,

(i) If there exists $Q \in \mathcal{M}_{e,b}(S, G)$, so that

$$p_t \leq E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}] | \mathcal{G}_t] \quad \text{a.s. for all } t < T, \quad (35)$$

then there is no IFA with bounded portfolio strategies ($NIFA^\infty$).

(ii) If there exists $t < T$, so that $p_t - E_P [X_{t,T} | \mathcal{H}_{t,T}]$ is bounded from above and the event that

$$p_t > \text{ess inf}_{Q \in \mathcal{M}_{e,b}(S, G)} E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}] | \mathcal{G}_t] \quad \text{and} \quad (36)$$

has positive probability under $P$, then there exists an IFA with bounded portfolio strategies.

**Proof.** Equation (5.2) is an immediate consequence of the part $(3.2) \Rightarrow (3.2)$ of Theorem 3.2, combined with the remark after Equation (34).

The proof of Equation (5.2) is similar to the one of Theorem 5.1: $\pi_t^\dagger := \text{ess inf}_{Q \in \mathcal{M}_{e,b}(S, G)} (p_t - E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}]]$) is the subhedging price of $p_t - E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}]]$, which is bounded from above. Restricted to the event $A_t$ defined in Equation (37), we get a subhedging strategy $\xi = 1_{A_t} (\xi_t, \ldots, \xi_{T-1})$ so that

$$1_{A_t} (p_t - E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}]] + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \geq 1_{A_t} \pi_t^\dagger. \quad (38)$$

Again we have with $\pi_t^\dagger := \text{ess sup}_{Q \in \mathcal{M}_{e,b}(S, G)} (p_t - E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}] | \mathcal{G}_t])$ on the set $A_t \cap \{\pi_t^\dagger = \pi_t^\dagger\}$ that

$$p_t - E_Q [E_P [X_{t,T} | \mathcal{H}_{t,T}]] + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s = \pi_t^\dagger > 0,$$

by Equation (37), while on

$$A_t \cap \{\pi_t^\dagger > \pi_t^\dagger\}$$
we get
\[ p_t - E_Q[EP[X_{t,T} | \mathcal{H}_{t,T}]] + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s > \pi_t^i \geq 0 \]
by Equation (36), which implies that
\[ 1_{A_i} \left( p_t - E_Q[EP[X_{t,T} | \mathcal{H}_{t,T}]] + \sum_{s=t}^{T-1} \xi_s \cdot \Delta S_s \in L^0_+ \setminus \{0\} \right). \tag{39} \]
Now, the construction of a bounded portfolio strategy leading to an IFA is identical to the one given in the proof of Theorem 5.1. \hfill \square

6 | INSURANCE–FINANCE CONSISTENCY OF ANNUITY CONTRACTS

In this section, we consider annuity contracts in order to illustrate the application of our results. We retain the situation of Section 5 where we had the nested sequence of filtrations
\[ \mathcal{F}_t \subset \mathcal{G}_t \subset \mathcal{H}_t \quad \text{for all } t \in \mathbb{T}. \]
and a finance consistent measure on the filtration \( \mathcal{G} \);
\[ \mathcal{M}_{e,b}(S, \mathcal{G}) \neq \emptyset. \]
We begin by inquiring the situation of a progressive enlargement of the financial filtration \( \mathcal{G} \). We highlight explicitly that \( \mathcal{G}_0 \) is not assumed to be trivial.

6.1 | Progressive enlargement

We want to introduce an additional structure on \( \mathcal{G} \) by utilizing the theory of progressive enlargements. For a detailed study of this theory and many references to related literature, see Aksamit and Jeanblanc (2017) and Blanchet-Scalliet and Jeanblanc (2020).

In this regard, let
\[ G = (G_{t,i})_{1 \leq i \leq n_t, t \in \mathbb{T}} \]
be a nested sequence of finite partitions of \( \Omega \), meaning that we have
\[ (i) \quad G_{t,i} \cap G_{t,j} = \emptyset \quad \text{for all } t \in \mathbb{T}, i \neq j \leq n_t, \quad \text{and} \]
\[ (ii) \quad G_{t,i} = \bigcup \{ G_{t+1,j} \mid G_{t+1,j} \subset G_{t,i} \} \quad \text{for all } t < T, i \leq n_t. \tag{40} \]
Without loss of generality, we may assume that \( \bigcup_{i \leq n_0} G_{0,i} = \Omega \). The filtration
\[
\tilde{\mathcal{G}} = (\tilde{\mathcal{G}}_t)_{t \in \mathbb{T}} \quad \text{with} \quad \tilde{\mathcal{G}}_t := \mathcal{G}_t \vee \{ G_{t,i} \mid i \leq n_t \} \subset \mathcal{H}_t
\]
is called the **progressive enlargement** of \( \mathcal{G} \) under the partition sequence \( G \) and we provide an example in Section 6.2 below.

Note that in this setting, for any \( \tilde{\mathcal{G}}_t \)-measurable random variable \( Y_t \), we find \( \mathcal{G}_t \)-measurable random variables \( Y_{t,i}, 1 \leq i \leq n_t \), such that \( Y_t = \sum_{i \leq n_t} 1_{G_{t,i}} Y_{t,i} \). Therefore, a (discounted) \( \tilde{\mathcal{G}} \)-adapted financial flow \( X = (X_t)_{1 \leq t \leq T} \) (here we write simply \( X_t \) instead of \( X_{t,T} \) as in previous sections) can be written in the form
\[
X_t = \sum_{i=1}^{n_t} 1_{G_{t,i}} X_{t,i}
\]
with \( \mathcal{G}_t \)-measurable \( X_{t,i}, i \leq n_t \). Our goal is to value this flow \( X \) in an IFA-free way by applying the QP-rule. To this end, we define the densities
\[
L_{t,i} := Q \odot P(G_{t,i} \mid \mathcal{G}_t), \quad t \in \mathbb{T}, \ i \leq n_t.
\]

The conditional expectation of the flow \( X \) under the \( Q \odot P \)-measure can now be calculated as follows:

**Proposition 6.1.** Let \( \tilde{\mathcal{G}} \) be the progressive enlargement of \( \mathcal{G} \) under \( G \). Then, for any \( \tilde{\mathcal{G}} \)-adapted process \( X \), bounded from below, we have
\[
E_{Q \odot P} \left[ \sum_{1 \leq t \leq T} X_t \mid \tilde{\mathcal{G}}_0 \right] = \sum_{i \leq n_0} 1_{G_{0,i} \cap \{ L_{0,i} > 0 \}} \left( L_{0,i}^{-1} \sum_{1 \leq t \leq T} \sum_{1 \leq j \leq n_t} E_Q \left[ X_{t,j} L_{t,i} \mid \mathcal{G}_0 \right] \right).
\]

**Proof.** It suffices to prove Equation (44) on each set \( G_{0,i} \cap \{ L_{0,i} > 0 \}, i \leq n_0 \). There we have
\[
1_{G_{0,i} \cap \{ L_{0,i} > 0 \}} L_{0,i} E_{Q \odot P} \left[ \sum_{1 \leq t \leq T} X_t \mid \mathcal{G}_0 \cap \mathcal{G}_0 \right] = 1_{G_{0,i} \cap \{ L_{0,i} > 0 \}} E_{Q \odot P} \left[ \sum_{1 \leq t \leq T} X_t \mid \mathcal{G}_0 \right] = \sum_{i \leq n_0} 1_{G_{0,i} \cap \{ L_{0,i} > 0 \}} \sum_{1 \leq t \leq T} \sum_{1 \leq j \leq n_t} E_{Q \odot P} \left[ X_{t,j} 1_{G_{t,i}} \mid \mathcal{G}_0 \right].
\]
Next,
\[
E_{Q \odot P} \left[ X_{t,j} 1_{G_{t,j}} \mid \mathcal{G}_0 \right] = \sum_{1 \leq t \leq T} \sum_{1 \leq j \leq n_t} E_{Q \odot P} \left[ X_{t,j} 1_{G_{t,j}} \mid \mathcal{G}_t \right] = E_{Q \odot P} \left[ X_{t,j} Q \odot P(G_{t,j} \mid \mathcal{G}_t) \mid \mathcal{G}_0 \right] = E_{Q \odot P} \left[ X_{t,j} L_{t,j} \mid \mathcal{G}_0 \right]
\]
which shows Equation (44). \( \square \)
6.2 An annuity contract

We consider a standard contract of annuity type issued at date 0. Besides the information contained in \( \mathcal{G}_0 \), the benefits of the contract depend on the events of death, surrender, or survival up to date \( T \).

We recall that \( \mathcal{G}_0 \) is not trivial. The benefits are the death benefits (DB), the surrender benefits (SB), or the accumulated benefits (AB), see Ballotta et al. (2019) for further references and details. Let \( \sigma \) and \( \tau \) denote the random times of surrender and death, respectively, and assume that \( \sigma > 0 \), \( \tau > 0 \), to avoid trivialities.

The (already discounted) death benefit at time \( t \), say \( X_t^1 \in L^0(\Omega, \mathcal{G}_t, P) \), is paid if \( \tau = t \) and \( \sigma > t \). Hence, it is of the form

\[
DB_t = \mathbb{1}_{\{t = \tau < \sigma \land T\}} X_t^1.
\]

The (discounted) surrender benefit at time \( t < T \), say \( X_t^2 \in L^0(\Omega, \mathcal{G}_t, P) \), is paid if \( \sigma = t \) and \( \tau \geq \sigma \); and the (discounted) accumulation benefit, say \( X_T^3 \in L^0(\Omega, \mathcal{G}_T, P) \), is paid at \( T \) if \( \sigma, \tau \geq T \) leading to

\[
SB_t = \mathbb{1}_{\{t = \sigma \leq \tau, t < T\}} X_t^2
\]
\[
AB_T = \mathbb{1}_{\{T \leq \sigma \land \tau\}} X_T^3.
\]

The flow of the total benefit \( B = (B_t)_{1 \leq t \leq T} \) accumulates the individual benefits and is given by

\[
B_t = DB_t + SB_t + AB_t. \quad (45)
\]

According to the relevant events of survival and death we build up the partition \( G \). Intuitively, we decide at time \( t \) if death occurred, surrender, or none of these. This leads to the following: \( n_0 = 1 \) and \( G_{0,1} = \Omega \). Moreover, for \( 1 \leq t \leq T \), we set \( G_{t,j} = G_{t-1,j} \), for \( 1 \leq j \leq 2(t - 1) \), and

\[
G_{t,2t+1} = G_{t-1,2t+1} \cap \{t = \tau < \sigma \land T\},
\]
\[
G_{t,2t+2} = G_{t-1,2t+1} \cap \{t = \sigma \leq \tau\},
\]
\[
G_{t,2t+3} = G_{t-1,2t+1} \cap \{t < \sigma \land \tau\}. \quad (46)
\]

This partition allows us to rewrite the benefits as follows:

\[
DB_t = \mathbb{1}_{G_{t,2t+1} \cup G_{t,2t+2} \cup G_{t,2t+3}} X_t^1,
\]
\[
SB_t = \mathbb{1}_{G_{t,2t+1} \cup G_{t,2t+2} \cup G_{t,2t+3}} X_t^2,
\]
\[
AB_T = \mathbb{1}_{G_{t,2t+1} \cup G_{t,2t+2} \cup G_{t,2t+3}} X_T^3, \quad (47)
\]

and we obtain the following valuation rule for a measure \( Q \in \mathcal{M}_{e,b}(S, \mathcal{G}) \).

**Proposition 6.2.** A premium \( p_0 \) for the flow of benefits described in Equation (45) satisfies NIFA\( ^\infty \) if

\[
p_0 \leq \sum_{t=1}^{T-1} E_Q \left[ X_t^1 L_{t,2t+1} + X_t^2 L_{t,2t+2} + X_T^3 L_{T-1,2T-1} \bigg| \mathcal{G}_0 \right]. \quad (48)
\]
Proof. From Proposition 6.1, we obtain

\[
E_{\Omega \otimes P}[DB_t | \mathcal{G}_0] = 1_{G_0 \cap \{L_0 > 0\}} L_0^{-1} E_Q [X_t^1 L_t,2t+1 | \mathcal{G}_0],
\]

\[
E_{\Omega \otimes P}[SB_t | \mathcal{G}_0] = 1_{G_0 \cap \{L_0 > 0\}} L_0^{-1} E_Q [X_t^2 L_t,2t+2 | \mathcal{G}_0],
\]

\[
E_{\Omega \otimes P}[AB_T | \mathcal{G}_0] = 1_{G_0 \cap \{L_0 > 0\}} L_0^{-1} E_Q [X_T^3 L_{T-1,2T-1} | \mathcal{G}_0],
\]

(49)

where again \( L_0 = Q \otimes P(G_0 | \mathcal{G}_0) \) and \( L_t,j = Q \otimes P(G_{t,j} | \mathcal{G}_t) \) for \( 1 \leq j \leq 2t + 1 \), and \( 1 \leq t \leq T \). From the condition (35) of the Corollary 5.2, we get the concluding result. \( \square \)

Remark 6.3. It is possible to extend the setting to the case where \( \tilde{\mathcal{G}}_0 \) is an enlargement of \( \mathcal{G}_0 \) by the finite partition \( G_0 = \{G_{0,1}, ... , G_{0,n_0}\} \) of \( \Omega \) according to Equation (41). To avoid lengthy formulas, we stucked to the simpler case above.

7 | CONCLUSION

In analogy to the FTAP, the paper defines and investigates arbitrage in the more challenging situation of an insurance company, which besides its large portfolio of contracts has the possibility to hedge its risks in a financial market. The corresponding fundamental theorem provides so called insurance–finance-consistent measures, but unfortunately, they lack the connection to the statistical data of the company. The QP-rule is the state of the art for this connection; consequently, its insurance–finance consistency has to be analyzed.

In the context of a linear relation between premiums and benefits, our work can be seen as the first step towards a general study of the consistency of insurance flows. Future work will be needed to include nonlinear entities, like risk measures and SCR, and should take the possible regulated transfer of insurance risk from a ruined company to another into account.

APPENDIX A: THE KEY PROPOSITION

The following considerations based on ideas in Chapter 6 of Delbaen and Schachermayer (2006). See also Schachermayer (1992) where the projection method below appeared for the first time. Similar results are given in Kabanov and Stricker (2006). For the convenience of the reader, we provide a complete proof of the Key Proposition A.3. For some readers, it may be interesting in its own right.

For $t = 0, \ldots, T - 1$, we define backward recursively the following $\mathcal{G}_t$-stable subspace of $L^0(\mathcal{G}_t)$:

First we have the kernel of the linear mapping $\xi_t \mapsto x_i \cdot \Delta S_t$:

$$\tilde{\mathcal{H}}_t := \{ \xi_t \in L^0(\mathcal{G}_t) \mid \xi_t \cdot \Delta S_t = 0 \}.$$

By Lemma 6.2.1, in Delbaen and Schachermayer (2006), we get a $\mathcal{G}_t$-measurable projection $\tilde{\rho}_t$ so that

$$\xi_t \in \tilde{\mathcal{H}}_t \iff \tilde{\rho}_t(\xi_t) = \xi_t.$$

The orthogonal complement is

$$\tilde{\mathcal{N}}_t := \{ \xi_t \in L^0(\mathcal{G}_t) \mid (Id - \tilde{\rho}_t)(\xi_t) = 0 \}.$$

For $t = T - 1$, we set $\mathcal{N}_{T-1} = \tilde{\mathcal{N}}_{T-1}$. For $t < T - 1$, assume that the sets $\mathcal{M}_s$ and $\mathcal{N}_s$ are already defined for $t < s \leq T - 1$. We consider the linear mapping

$$\mathcal{F}_t : \bigotimes_{t < s \leq T-1} (\mathcal{M}_s \times \mathcal{N}_s) \longrightarrow L^0(\mathcal{H}_{T-1,T}),$$

$$\mathcal{F}_t((\gamma_s, \xi_s)_{t < s \leq T-1}) = \sum_{t < s \leq T-1} \gamma_s \cdot Y_{s,T} + \xi_s \cdot \Delta S_s.$$
We now turn to the analogous definitions of $\mathfrak{M}_t$, starting with the kernel

$$\widetilde{\mathfrak{M}}_t := \{ \gamma_t \in L^0_+ (\mathcal{G}_t) \mid \gamma_t \cdot Y_{t,T} = 0 \},$$

and let $\widetilde{\pi}_t$ be the projection on $\widetilde{\mathfrak{M}}_t$ with

$$\gamma_t \in \widetilde{\mathfrak{M}}_t \iff \widetilde{\pi}_t(\gamma_t) = \gamma_t$$

and the orthogonal complement

$$\mathfrak{M}_t := \{ \gamma_t \in L^0_+ (\mathcal{G}_t) \mid (Id - \widetilde{\pi}_t)(\gamma_t) = \gamma_t \}.$$

Here, we consider the linear mapping

$$\mathfrak{I}_t : \mathfrak{N}_t \times \bigotimes_{t \leq s \leq T-1} (\mathfrak{M}_s \times \mathfrak{N}_s) \longrightarrow L^0_+ (\mathcal{H}_{T-1,T}),$$

$$\mathfrak{I}_t(\xi_t, (\gamma_s, \xi_s)_{t \leq s \leq T-1}) := \xi_t \cdot \Delta S_t + \sum_{t < s \leq T-1} \gamma_s \cdot Y_{s,T} + \xi_s \cdot \Delta S_s.$$  

Note that for $t = T - 1$, the map $\mathfrak{I}_{T-1}$ is defined only on $\mathfrak{N}_{T-1}$, which is defined above. We consider the extended kernel

$$\widetilde{\mathfrak{M}}_t := (\mathfrak{I}_t)^{-1} \left( \mathfrak{I}_t \left( \mathfrak{N}_t \times \bigotimes_{s=1+1}^{T-1} (\mathfrak{M}_s \times \mathfrak{N}_s) \right) \cap \{ \gamma_t \cdot Y_{t,T} \mid \gamma_t \in L^0_+ (\mathcal{G}_t) \} \right).$$

entailing the projection $\widetilde{\pi}_t$ on $\widetilde{\mathfrak{M}}_t$:

$$\gamma_t \in \widetilde{\mathfrak{M}}_t \iff \widetilde{\pi}_t(\gamma_t) = \gamma_t$$

Finally, its orthogonal complement is

$$\mathfrak{M}_t := \{ \gamma_t \in L^0_+ (\mathcal{G}_t) \mid (Id - \widetilde{\pi}_t)(\gamma_t) = \gamma_t \}.$$

Note that $1_{\{Y_{t,T}=0\}} \mathfrak{N}_t = \{0\}$ and $1_{\{\Delta S_t=0\}} \mathfrak{M}_t = \{0\}$.

We say that $((\gamma_t, \xi_t))_{0 \leq t \leq T-1}$ is in canonical form if $\gamma_t \in \mathfrak{M}_t$ and $\xi_t \in \mathfrak{N}_t$ for all $0 \leq t \leq T - 1$.

As a first result, we have the following Proposition:

**Proposition A.1.** The mapping

$$\mathfrak{I} : \bigotimes_{0 \leq t \leq T-1} (\mathfrak{M}_t \times \mathfrak{N}_t) \longrightarrow L^0_+ (\mathcal{H}_{T-1,T}),$$

$$\mathfrak{I}(\gamma_t, \xi_t)_{0 \leq t \leq T-1}) := \sum_{0 \leq t \leq T-1} \gamma_t \cdot Y_{t,T} + \xi_t \cdot \Delta S_t.$$  

is injective.

**Proof.** Set $f_t = \sum_{s \leq t \leq T-1} \gamma_s \cdot Y_{s,T} + \xi_s \cdot \Delta S_s$ and assume that $t_0$ is the maximal time with $f_0 = f_{t_0}$. Then for $s < t_0$, we have $f_0 \in \mathfrak{I}_s(\bigotimes_{s \leq t \leq T-1} (\mathfrak{M}_t \times \mathfrak{N}_t)) \cap \mathfrak{I}_s(\{0\} \times \bigotimes_{s \leq t \leq T-1} (\mathfrak{M}_t \times \mathfrak{N}_t))$ such that $\gamma_s \in \widetilde{\mathfrak{M}}_s \cap \mathfrak{M}_s = \{0\}$ and $\xi_s \in \mathfrak{N}_s \cap \mathfrak{N}_s = \{0\}$. This shows $(\gamma_s, \xi_s) = (0, 0)$ for $s < t_0$. Next
assume that \( f_{t_0} \in \mathfrak{F}_{t_0} \times \mathcal{X}_{t_0} \), which implies \( \gamma_{t_0} \in \widetilde{\mathfrak{M}}_{t_0} \cap \mathfrak{M}_{t_0} = \{0\} \), hence \( \gamma_{t_0} = 0 \) again. Otherwise \( \gamma_{t_0} \cdot Y_{t_0,T} \neq 0 \) and \( \gamma_{t_0} \in \mathfrak{M}_{t_0} \) is unique. Now regard \( \widetilde{f}_{t_0} = \xi_{t_0} \cdot S_{t_0} + f_{t_0+1} \cdot \xi_{t_0} \in \mathfrak{F}_{t_0} \times \mathcal{X}_{t_0} \), then \( \xi_{t_0} \in \widetilde{\mathfrak{M}}_{t_0} \cap \mathfrak{M}_{t_0} = \{0\} \), that is, \( \xi_{t_0} = 0 \). Otherwise \( \xi_{t_0} \cdot S_{t_0} \neq 0 \) and \( \xi_{t_0} \in \mathfrak{M}_{t_0} \) is unique. The uniqueness of \( (\gamma_s, \xi_s) \) for \( s > t_0 \) follows by the induction hypothesis. \( \square \)

Another preliminary result is the following Proposition:

**Proposition A.2.** Assume condition (3.2) of Theorem 3.2 and \((\gamma^n, \xi^n)\) is a sequence of canonical form, that is, \((\gamma^n_t, \xi^n_t) \in \mathfrak{M}_t \times \mathfrak{M}_t\). Then we have

\[
(\gamma^n, \xi^n) \text{ is bounded a.s.} \iff \left( \sum_{i=0}^{T-1} (\gamma^n_i \cdot Y_{i,T} + \xi^n_i \cdot S_i) \right)_{-} \text{ is bounded a.s.}
\]

**Proof.** The \( \implies \)-part is trivial. The inverse direction is proved by induction on \( T \). For \( T = 0 \), there is nothing to show. For \( T \geq 1 \), we regard a sequence

\[
(\gamma^n, \xi^n) = ( (\gamma^n_0, \xi^n_0), \ldots (\gamma^n_{T-1}, \xi^n_{T-1}) ) \tag{A.1}
\]

and set for \( 0 \leq t \leq T - 1 \)

\[
V^n_t := \sum_{\tau=t}^{T-1} (\gamma^n_\tau \cdot Y_{\tau,T} + \xi^n_\tau \cdot S_{\tau} ). \tag{A.2}
\]

First assume that the set

\[
A := \left\{ \liminf \gamma^n_0 + \| \xi^n_0 \| = \infty \right\} \in \mathcal{G}_0
\]

has positive measure \( P(A) > 0 \). We divide the set \( A \) into two subsets:

\[
A_1 := A \cap \left\{ \liminf \| \xi^n_0 \| / \gamma^n_0 = 0, \gamma^n_0 \geq 1 \right\},
\]

\[
A_2 := A \cap \left\{ \liminf \| \gamma^n_0 \| / \| \xi^n_0 \| < \infty, \| \xi^n_0 \| \geq 1 \right\}.
\]

Assume first that \( P(A_1) > 0 \). Note that we do not have \( Y_{0,T} = 0 \) a.s. on \( A_1 \) since the \( \gamma^n_0 > 0 \) on \( A_1 \) are in canonical form. By the measurable selection principle (see Delbaen & Schachermayer, 2006 Proposition 6.3.3.), we find a \( \mathcal{G}_0 \)-measurable subsequence \( T^n \) so that \( \gamma^n_t \to \infty \) and \( \| \xi^n_0 \| / \gamma^n_0 \to 0 \) on the set \( A_1 \). Then,

\[
1_{A_1} Y_{0,T} = 1_{A_1} \lim_n \left( \gamma^n_0 \cdot Y_{0,T} + \xi^n_0 \cdot S_{0} \right) / \gamma^n_0
\]

and

\[
1_{A_1} \limsup_n \left( V^n_1 / \gamma^n_0 \right) \leq 1_{A_1} \limsup_n \left( V^n_0 / \gamma^n_0 \right) + \limsup_n \left( \left( \gamma^n_0 \cdot Y_{0,T} + \xi^n_0 \cdot S_{0} \right) / \gamma^n_0 \right)
\]

\[
\leq |Y_{0,T}|
\]

since \( 1_{A_1} \limsup_n (V^n_1 / \gamma^n_0) = 0 \) by assumption. Hence, \( (V^n_1 / \gamma^n_0) \) is bounded on \( A_1 \) and so is \( 1_{A_1} ((\gamma^n_1, \xi^n_1), \ldots (\gamma^n_{T-1}, \xi^n_{T-1})) / \gamma^n_0 \) by induction hypothesis. By a number of applications of the
measurable selection principle, we get series of iterated subsequences $\sigma^n_t$ up to $\sigma^n_{T-1}$ so that for $1 \leq t \leq T - 1$, we have

$$1_{A_1} \lim_n (y^n_T, \xi^n_T)/y^n_0 = 1_{A_1} \lim_n (y^n_{T-1}, \xi^n_{T-1})/y^n_0 = (\bar{y}_1, \bar{\xi}_1)$$

for some $(\bar{y}_1, \bar{\xi}_1) \in L^0(\mathcal{G}_1) \times L^0(\mathcal{G}_1)$. Therefore,

$$1_{A_1} \lim_n V^n_{0,T-1}/y^n_0 = 1_{A_1} \left( Y_{0,T} + \sum_{\tau=1}^{T-1} (\bar{y}_\tau \cdot Y_{\tau,T} + \bar{\xi}_\tau \cdot \Delta S_{\tau}) \right) =: 1_{A_1} Y_{0,T} + \bar{V}_1.$$

While we still have $1_{A_1} \lim_n (Y_{0,T} + V^n_{0,T-1}/y^n_0) - = 0$ it follows that $1_{A_1} Y_{0,T} + \bar{V}_1 \geq 0$ and condition (3.2) of Theorem 3.2 implies that $1_{A_1} Y_{0,T} + \bar{V}_1 = 0$. This contradicts Proposition A.1 according to which the coefficient of $Y_{0,T}$ must be 0.

Next let $P(A_2) > 0$. Here, the selection principle yields a $\mathcal{G}_0$-measurable subsequence $\tau^n$ so that $||\xi^n_0|| \to \infty$, $\lim_n \xi^n_0 / ||\xi^n_0|| = \xi_0$ with $||\xi_0|| = 1$, and $\lim_n y^n_{\tau^n} / ||\xi^n_0|| = \gamma_0 < \infty$ on the set $A_2$. We define

$$\bar{\xi}_0 := 1_{A_2} \xi_0 \in \mathcal{N}_0 \setminus \{0\} \quad \text{and} \quad \bar{y}_0 := 1_{A_2} y_0 \in \mathcal{N}_0.$$

With similar arguments as above, we have

$$\bar{y}_0 \cdot Y_{0,T} + \bar{\xi}_0 \cdot \Delta S_0 = 1_{A_2} \lim_n \left( y^n_0 \cdot Y_{0,T} + \xi^n_0 \cdot \Delta S_0 \right) / ||\xi^n_0|| \quad \text{and}$$

$$1_{A_2} \limsup_n \frac{V^n_{1}}{||\xi^n_0||} \leq 1_{A_2} \limsup_n \frac{(V^n_0)}{||\xi^n_0||} + \limsup_n \left( y^n_0 \cdot Y_{0,T} + \xi^n_0 \cdot \Delta S_0 \right) / ||\xi^n_0||$$

$$\leq |\bar{y}_0 \cdot Y_{0,T} + \bar{\xi}_0 \cdot \Delta S_0|$$

and by induction hypothesis $1_{A_2} ((\gamma^n_1, \xi^n_1), \ldots (\gamma^n_{T-1}, \xi^n_{T-1}))/||\xi^n_0||$ is bounded. Again, iterated applications of the selection principle yield elements $(y^n_t, \xi^n_t) \in 1_{A_2} (\mathcal{N}_t, \mathcal{N}_t)$ for $t = 1, \ldots, T-1$ with

$$1_{A_2} \lim_n V^n_{0,T-1}/||\xi^n_{T-1}|| = \bar{y}_0 \cdot Y_{0,T} + \bar{\xi}_0 \cdot \Delta S_0 + \sum_{\tau=1}^{T-1} (\bar{y}_\tau \cdot Y_{\tau,T} + \bar{\xi}_\tau \cdot \Delta S_{\tau})$$

$$=: \bar{V}_0 =: \bar{y}_0 \cdot Y_{0,T} + \bar{\xi}_0 \cdot \Delta S_0 + \bar{V}_1.$$

Since $(\bar{V}_0)_- = 0$, condition (3.2) of theorem yields $\bar{V}_0 = 0$ contradicting by Proposition A.1 the coefficient $\bar{\xi}_0$ since $||\xi_0|| = 1$.

Thus, the sequence $(y^n_0, \xi^n_0)$ is bounded. Once again

$$(V^n_1)_- \leq (V^n_0)_- + (y^n_0 \cdot Y_{0,T} + \xi^n_0 \cdot \Delta S_0)_-$$

shows that $(V^n_0)_-$ is bounded and induction hypothesis gives us that for $1 \leq t \leq T - 1$, the sequences $(y^n_t, \xi^n_t)$ are bounded, too.
With the last two propositions, we arrive at the main proposition needed to the last part of the proof of Theorem 3.2.

**Proposition A.3.** Under condition (3.2) of Theorem 3.2 and with \( \mathcal{K} \) from Equation (14), the cone
\[ \mathcal{K} = L^0_+(\mathcal{H}_{T-1,T}) \]
is closed.

**Proof.** With the notations from Equations (A.1) and (A.2), let \((y^n, \xi^n)\) be a sequence in canonical form so that \(V^n_0 - H^n \longrightarrow G\) for a sequence \(H^n \in L^0_+(\mathcal{H}_{T-1,T})\) and \(G \in L^0(\mathcal{H}_{T-1,T})\). Since \(\liminf_n V^n_0 \geq G\), we have \(\limsup_n (V^n)_- \geq G_-\) and \((V^n)_-\) is bounded. So the sequence \((y^n, \xi^n)\) is bounded by Proposition A.2. As in the proof before, iterated applications of the measurable selection principle yield that \((y^n,\xi^n) \in \mathcal{Y}_t \times \mathcal{H}_t\) and \(\lim_n V^n_0 = \sum_{t=0}^{T-1} Y_t \cdot Y_{t,T-1} + \xi_t \cdot \Delta S_t =: V_0\). Then, \(H^{\xi^n} \longrightarrow V_0 - G \geq 0\) and \(V_0 - (V_0 - G) \in \mathcal{K} - L^0_+(\mathcal{H}_{T-1,T})\). \(\square\)

**APPENDIX B: EVALUATION OF INSURANCE RESULTS**

**Proposition B.1.** Under Assumption 2.2 and the admissibility condition, we have for all bounded portfolio strategies \(\psi\), all \(L_{t,T} \in L^\infty(\mathcal{H}_{t,T})\) and all \(t = 0, \ldots, T-1\), that
\[
E_P\left[L_{t,T} \lim_{n \to \infty} \sum_{i \geq 1} \psi_i^{n,i} p_t \right] = E_P[L_{t,T} \gamma_t p_t], \quad \text{and} \quad \text{(B.1)}
\]
\[
E_P\left[L_{t,T} \lim_{n \to \infty} \sum_{i \geq 1} \psi_i^{n,i} X_t^{i,T} \right] = E_P[L_{t,T} \gamma_t E_P[X_t^{i,T} | \mathcal{H}_{t,T}]]. \quad \text{(B.2)}
\]

**Proof.** Indeed, Equation (B.1) follows from the convergence of the insurance volume in Equation (4).

To prove Equation (B.2), we first show that \((\sum_{i \geq 1} \psi_i^{n,i} X_t^{i,T})_n \in \mathbb{N}\) is uniformly integrable. It holds
\[
E_P\left[\left(\sum_{i \geq 1} \psi_i^{n,i} X_t^{i,T}\right)^2\right] = E_P\left[E_P\left[\left(\sum_{i \geq 1} \psi_i^{n,i} X_t^{i,T}\right)^2 | \mathcal{H}_{t,T}\right]\right]
\]
\[
= E_P\left[\sum_{i,j \geq 1} E_P\left[\psi_i^{n,i} X_t^{i,T} \psi_j^{n,j} X_t^{j,T} | \mathcal{H}_{t,T}\right]\right]
\]
\[
= E_P\left[\sum_{i,j \geq 1} \psi_i^{n,i} \psi_j^{n,j} E_P\left[X_t^{i,T} X_t^{j,T} | \mathcal{H}_{t,T}\right]\right]. \quad \text{(B.3)}
\]

Assumption 2.2 yields that
\[
(B.3) \leq E_P\left[\sum_{i \neq j \geq 1} \psi_i^{n,i} \psi_j^{n,j} E_P\left[X_t^{i,T} | \mathcal{H}_{t,T}\right]^2\right] + E_P\left[\sum_{i \geq 1} (\psi_i^{n,i})^2 E_P\left[X_t^{i,T} | \mathcal{H}_{t,T}\right]^2\right] < \infty.
\]
uniformly in $n \in \mathbb{N}$. Hence, we obtain uniform integrability of $\sum_{i \geq 1} \psi^i_n X^i_{t,T}$. From this, it follows that

$$\int L_{t,T} E_P \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n X^i_{t,T} | \mathcal{H}_{t,T} \right] dP = \int L_{t,T} \lim_{n \to \infty} E_P \left[ \sum_{i \geq 1} \psi^i_n X^i_{t,T} | \mathcal{H}_{t,T} \right] dP$$

$$= \int L_{t,T} \lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n E_P \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right] dP$$

$$= \int L_{t,T} \gamma_t E_P \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right] dP,$$

and the claim is proven. \(\square\)

Since we will consider $P^* \sim P$, a portfolio strategy $\psi$ is admissible under $P$, iff it is admissible under $P^*$.

**Proposition B.2.** Assume that Assumption 2.2 holds (under $P$). Consider a measure $P^*$ under which Assumption 3.1 is satisfied, let $\psi$ be a bounded and admissible portfolio strategy $\psi$, and $t = 0, \ldots, T - 1$. Then,

$$E_{P^*} \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n X^i_{t,T} \right] = E_{P^*} \left[ \gamma_t E_P \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right] \right].$$

(B.5)

**Proof.** Since $P \sim P^*$ almost sure limit results persist under this change of measure. Since from Assumption 2.2, we obtain as in the proof of Proposition B.1 that $(\sum_{i \geq 1} \psi^i_n X^i_{t,T})_{n \in \mathbb{N}}$ is uniformly integrable under $P$, it is uniformly integrable under $P^*$.

As in Equation (B.4), we obtain

$$\int E_{P^*} \left[ \lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n X^i_{t,T} | \mathcal{H}_{t,T} \right] dP^* = \int \lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n E_{P^*} \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right] dP^*$$

$$= \int \gamma_t E_{P^*} \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right] dP^*. \quad \text{(B.6)}$$

Finally, we observe that under Assumption 2.2, the uniform portfolio strategy

$$\psi_t^n = (1/n, \ldots, 1/n, 0 \ldots),$$

together with the conditional strong law of large numbers in Majerek et al. (2005) gives for this allocation the following result:

$$\lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n X^i_{t,T} = E_P \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right]$$

on a measurable set $A$ with $P(A) = 1$. Under $P^*$, we obtain similarly

$$\lim_{n \to \infty} \sum_{i \geq 1} \psi^i_n X^i_{t,T} = E_{P^*} \left[ X^i_{t,T} | \mathcal{H}_{t,T} \right].$$
on $A'$ with $P^*(A') = 1$. Since $P \sim P^*$, we obtain $E_{P^*}[X_{1,T}^1|\mathcal{H}_{1,T}] = E_P[X_{1,T}|\mathcal{H}_{1,T}]$ and the claim is proven. □

If the density $L = dP^*/dP$ is $\mathcal{H}_{0,T}$-measurable, then Equation (B.5) follows also by an Application of Proposition B.1. If, however, $L$ is not $\mathcal{H}_{0,T}$-measurable, we need Assumption 3.1.
