Summary
User surveys in telemedicine networks confirm that follow up data are essential, both for the specialists who provide advice and for those running the system. We have examined the feasibility of a method for obtaining follow-up data automatically in a store-and-forward network. We distinguish between follow-up, which is information about the progress of a patient and is based on outcomes, and user feedback, which is more general information about the telemedicine system itself, including user satisfaction and the benefits resulting from the use of telemedicine. In the present study, we were able to obtain both kinds of information using a single questionnaire. During a 9-month pilot trial in the MSF telemedicine network, an email request for information was sent automatically by the telemedicine system to each referrer exactly 21 days after the initial submission of the case. A total of 201 requests for information were issued by the system and these elicited 41 responses from referrers (a response rate of 20%). The responses were largely positive. For example, 95% of referrers found the advice helpful, 90% said that it clarified their diagnosis, 94% said that it assisted with management of the patient and 95% said that the telemedicine response was of educational benefit to them. Analysis of the characteristics of the referrers who did not respond, and their cases, did not suggest anything different about them in comparison with referrers who did respond. We were not able to identify obvious factors associated with a failure to respond. Obtaining data by automatic request is feasible. It provides useful information for specialists and for those running the network. Since obtaining follow-up data is essential to best practice, one proposal to improve the response rate is to simplify the automatic requests so that only patient follow-up information is asked for, and to restrict user feedback requests to the cases being assessed each month by the quality assurance (QA) panel.

Introduction
Follow up is an integral part of consultation in medical practice. No doctor would give advice about a patient without attempting to follow the patient's subsequent progress and/or trying to obtain some feedback. This basic principle is not altered when the consultation takes place at a distance (teleconsultation). Follow-up is part of routine clinical care, conducted in order to confirm that the situation is evolving as expected, and to allow the diagnosis, prognosis and treatment to be adjusted as appropriate. It is also important for doctors to learn from their successes and mistakes, as part of a reflective practice.[1]

Thus it is not surprising that surveys in telemedicine networks show that the specialists who provide advice wish to receive follow-up data about the cases they have worked on. In a survey of telemedicine users in Médecins Sans Frontières (MSF), almost all specialists wanted follow-up information (52% considered follow up desirable and 47% considered it necessary or mandatory).[2] In a survey of specialists in the Swinfen telemedicine network, 83% stated that they would like to receive follow-up information about the patient.[3] We assume that provision of follow-up data is useful in keeping the specialists motivated, i.e. to ensure their continued participation in the telemedicine network and their availability to provide advice. It is also probably the only way that specialists can improve their service, since many of them will be based in high-income countries and without feedback it is impossible for them to know if their answers are useful; prompt feedback from the referrer may be perceived as a mark of gratitude for the service provided, which is important since many specialists volunteer their time and expertise for free. While it can reasonably be
assumed that the provision of follow-up data is useful for many reasons, there is no literature about this (an experiment to test the assumption would be difficult, although not impossible).

Follow-up is also useful for those running the network, especially if a research study is to be conducted. Follow-up provides information about the value of the telemedicine consultations, and about the performance of individual specialists. Information about the latter is very valuable for the case coordinator in the allocation process, since experience shows that some specialists answer more quickly and comprehensively than others. Finally, providing follow-up data is probably good discipline for the referrers, as it makes them think about the progress of their patients and about the value of the telemedicine advice they have received.

In the present paper we distinguish between patient follow-up, which is information about the progress of a patient and is based on outcomes, and user feedback, which is more general information about the telemedicine system itself, including user satisfaction and the benefits resulting from the use of telemedicine.

**Objectives**

The primary Research Question was whether a method could be developed for obtaining follow-up data automatically in a general teleconsulting network which was providing a service in low resource settings. The secondary Research Question was whether it was feasible to obtain both follow-up data and user feedback simultaneously.

**Methods**

The present study required the development of a method to obtain data from the referrers and then a demonstration of its feasibility in practice. We combined the collection of both kinds of information into a single questionnaire, i.e. it represented a progress report.

The work was performed in two stages:

1. development of an information-collection tool
2. demonstration of its feasibility in the MSF telemedicine network. Details of the network have been published elsewhere.[2,4]

Ethics permission was not required, because patient consent to access the data had been obtained and the work was a retrospective chart review conducted by the organisation's staff in accordance with its research policies.

**Development of the questionnaire**

A questionnaire was developed by a consensus between three experienced telemedicine practitioners (two were medical specialists with field experience). It was based on accepted tools used in previous studies.[3,5] The final questionnaire was evaluated and approved by an independent evaluator.

The final questionnaire consisted of 12 questions, which concerned both patient follow-up and user feedback, Table 1. The questions about follow-up concerned the referrer's opinion about whether the eventual outcome would be beneficial for the patient. The questions about feedback concerned the referrer's opinion about whether the process was satisfactory (e.g. the way that the referral had been handled in the telemedicine network) and what the benefits
Automatic request for information
Modifications were made to the telemedicine system so that automatic requests for progress reports were sent to every referrer at a pre-determined interval after a new case had been submitted. The request allowed the referrer to log in to the server and then provided a link for the referrer to respond to the questionnaire.

Demonstration of feasibility
To demonstrate the feasibility of the proposed approach, automatic requests for progress reports were issued in respect of cases submitted in the MSF telemedicine network for a 9-month period starting in October 2013. An email request was sent automatically by the telemedicine system to each referrer exactly 21 days after the initial submission of the case. When the referrer completed the progress report, an email notification was sent simultaneously to the expert(s) involved in the case and to the case-coordinators.

Analysis of responses
Responses to the requests were analysed approximately four weeks after the final request had been sent. The free-text comments were examined and, based on a content analysis, the main themes were extracted.

Results
Analysis of responses
During the pilot trial, 201 requests for progress reports were issued by the system and these elicited 41 responses from referrers (a response rate of 20%). The responses were largely positive. For example, excluding the Don't-know and Missing responses, 95% of referrers stated that they found the advice helpful, 90% said that it clarified their diagnosis and 94% said that it assisted with management of the patient. In addition, 95% said that the telemedicine response was of educational benefit to them. The responses are summarised in Table 2a.

The qualitative analysis of the free comments confirmed this positive feedback from the responders, see Table 2b. The expert advice was considered by the referrer as “clear, comprehensive and useful”, helping both in the clinical management (diagnosis and management) and the information delivered to the patient and relatives. Referrers considered that the non-availability of an investigation or treatment that had been suggested was the main limitation in following the advice received. For this reason, some referrers emphasised the importance of making the expert aware of the constraints of the referral setting and the limited resources available.

Satisfaction with the system was also very high and the words used by responders emphasised the efficiency of the system ("excellent, very good quality, quick, practical …"). In terms of benefit, avoiding unnecessary referral to a higher level of health care or avoiding further specialised consultation were mentioned as the main reasons for cost savings.

Analysis of non-responses
During the pilot trial, questionnaires were completed for 41 cases. That is, no questionnaire was completed for the other 160 cases. These two groups of cases might have differed in
some way, and any difference might be a reason why the referrers decided to respond or not to respond. Various characteristics of the two groups were therefore compared. The median age of the patients in Group 1 (those with responses) was 27.5 years, and the median age of the patients in Group 2 (those without responses) was 22.0 years. However, the difference was not significant (\(P=0.13\)). There were no significant differences in the gender of the patients in the two groups, nor the type of queries required to answer them, nor the number of queries for each case, see Table 3.

Responders and non-responders
Six referrers provided progress reports for every request they received, see Table 4a. However, the majority provided either some reports, or none, see Table 4b. There were no obvious differences between the three groups (responders to all, some or none of the requests) in the characteristics available for comparison, see Table 6.

Discussion
The present work shows that both patient follow-up data and user feedback information can be obtained in a telemedicine network, via an automatic questionnaire. In a 9-month pilot trial, there was a response rate of 20%. How can we interpret this response rate? In physician surveys conducted in industrialised countries, a response rate of say 50-60% would be considered normal.[6,7] However, there is little published data about the response rate in online surveys of doctors in developing countries, and even less about the response rate in online surveys of doctors concerning the use of telemedicine in developing countries. A reasonable comparator is the study by Zolfo et al., of health-care workers using store-and-forward telemedicine in the management of difficult HIV/AIDS cases, which had a response rate of 19%.[8]

The dangers of a low response rate are non-response bias (if the answers provided by respondents differ from the potential answers of those who do not answer), and response bias (if respondents tend to give answers that they believe that the questioner wants). Analysis of the characteristics of the referrers who did not respond, and the cases, did not suggest anything different about them in comparison with referrers who did respond. The comparison of referrers was however limited by the restricted information available about them. For reasons of information security, the telemedicine system stores little personal information about the users, and the accounts tend to be used by more than one person as staff are rotated through the field.

We were not able to identify obvious factors associated with a failure to respond. The response rate may therefore simply reflect the pressures of working in low resource settings, and especially, the high turnover of field staff, which acts against the treating doctor being in post when a request for follow-up data is made some weeks later.

Measures to increase survey response rates are reasonably well understood, and include offering financial incentives, and following up online requests with copies of the survey sent out on paper. These are probably not appropriate in the present context. Nonetheless, it would seem prudent if this technique is to be adopted into routine service to try and increase the response rate. This raises a number of questions for future research:

1. when should follow-up data be requested? i.e. is 21 days the right time? Other
work[2] suggests that a shorter interval, such as one week, would be appropriate, see Table 5a

2. Is there an optimum time interval for all patients, or does the optimum time vary, depending on the speciality being consulted?

3. What is the right number of questions? i.e. is 12 questions too many? Reducing the survey to 2-3 questions might make a response more likely

4. Is it appropriate to ask for user feedback each time that a follow up report is requested? Should requests for user feedback be made separately from requests for follow-up data (and less frequently)?

5. Is a single follow-up report sufficient, or should there be say a short-term and a longer-term report?

As mentioned in the Introduction, it is highly desirable to obtain follow up data for each case. Even though there are other ways to obtain follow up information, e.g. from the regular dialogue between expert and referrer, the benefit of using an automatic request is that a standardized report is obtained for each case. Thus the main problem in practice is the low response rate, and how best to encourage the referrer to complete the questionnaire. One potential way to increase the response rate would be to reduce the number of questions, in order to allow the referrer to answer within 1-2 minutes. As shown in a previous survey,[2] the main reasons given for not answering were a lack of time > forgotten to update > patient lost to follow up > difficulties with Internet access (Table 5a, 5b). This is why we propose to separate the reporting of follow up data from obtaining user feedback.

If user feedback is solicited separately from the follow-up data, then a natural time to request it would be when the monthly quality assurance (QA) review is conducted.[9] This activity involves an expert panel making an assessment of a recent case that has been selected at random. If user feedback is requested from the referrer for the same case, then both the panel’s and the referrer’s views on the quality of the teleconsultation can be compared.

Finally, it is worth noting that specialists tend to underestimate the value of their responses. In a recent survey,[3] Patterson examined the perceived value of telemedicine advice. There were 62 cases where it was possible to match up the opinions of the referrer and the consultants about the value of a specific teleconsultation. In 34 cases (55%) the referrers and specialists agreed about the value. However, in 28 cases (45%) they did not: specialists marked underestimated the value of a consultation compared to referrers. A survey of MSF telemedicine users found a similar phenomenon.[2] This reinforces the importance of obtaining user feedback from the referrers, who are best placed to evaluate the benefits to the patient.

Conclusion
Obtaining data from referrers by automatic request is feasible. The technique provides useful information for specialists and for those running the network. The modest response rate could be improved. Since obtaining follow-up information on each case is essential to best practice, a proposal to improve the response rate is to re-design the follow up questionnaire to be as simple as possible, and to obtain user feedback separately, by sending a more detailed questionnaire in parallel with the randomly selected cases reviewed each month by the QA expert panel.

| Q5. If you could not follow the advice given, could you explain briefly why not | 16            | Main points     | Investigation not available (5)  
Treatment unavailable (3)  
Inability to perform investigation (2)  
Disagreement on expert diagnosis (2)  
Discharged against medical advice (2)  
Cost not affordable by patient  
Patient lost to follow up  
Advice not appropriate  
Not applicable                                                                                                                                                           |
| Q7e. Any other reason that you found the advice helpful                 | 16            | Main points     | Diagnosis clarified or confirmed (2)  
Differential diagnosis discussed (2)  
Helpful discussion about diagnosis and management (2)  
Triggered decision to transfer patient to specialist (2)  
Confidence in experienced specialist  
Advice “clear, comprehensive”  
Useful information about disease (nature, management, complication signs) for patient and relatives  
Technical advice about how to take an X-ray  
Support in CT scan interpretation  
Other comments:  
Patient left against medical advice  
Difficulties in implementing treatment advised (e.g. chronic disease)  
Treatment still in progress: too early to assess  
Not applicable                                                                                                                                                           |
| Q10b. If there was a saving for the patient/family, please explain briefly | 11            | Main points     | Avoid unnecessary referral to capital (4) because diagnosis given or chronicity of disease confirmed  
No further need for the patient to consult local specialists, saving both money and time (3)  
“Best diagnosis” obtained  
Clear information given to family and patient  
Avoid unnecessary harmful treatment or costly hospitalisation  
Early referral suggested for congenital cardiac disease (presenting from further complications)  
Specialised consultation not affordable by patient                                                                                                                                 |

10
| Q10d. If there was a saving for the hospital/clinic, please explain briefly | 12 | Main points |
|---|---|---|
| | | Avoid unnecessary referral to specialist (3) |
| | | No need to send investigation for interpretation (3) |
| | | Avoid unnecessary and costly investigation |
| | | Ambulatory management avoiding costly hospitalisation |
| | | Strengthened local staff decision to avoid costly referral |
| | | Clear information helped management |
| | | Not applicable (2) |

| Q11. Please add any other comments about this case specifically | 18 | About patient outcome |
|---|---|---|
| About advice | “Very helpful” both for diagnosis and patient information, “excellent”, “very practical and realistic advice with our set up” |
| | Helpful for X ray interpretation |
| | Useful guidance for specialised treatment |

| About case | Critical cases with ICU transfer (2) |
|---|---|
| | Difficult case, but a feeling to have “offered everything we can” |
| | Difficult case, but a feeling that “comments improved both patient management and staff knowledge” |
| | Specialised surgical treatment performed |

| To be improved | Problem of implementing expert advice in limited resource-settings |
|---|---|
| | More detailed X-ray interpretation for educational purposes |
| | X-ray interpretation not appropriate |
| | Difficult to upload a large file to the server |
| | Expert to be better informed about limited resource settings to adapt better their advice |
| | Appropriateness and usefulness of expert advice improved after several emails (from “Eurocentric -- further investigations and management recommended -- to field centred”) |
| Q12. Please add any other comments about the service generally | 17 | Service | “Excellent” (3)  
“Very rapid and extremely useful to the field and consequently the patients”  
“Very useful- practical and informative”  
“Appreciated a lot” (2), “appreciated really”  
“Important with benefit for both client and medical personnel”  
“Effective” because quick answer  
“Very good quality and helpful”  
“Is the best.”  
“Really quick with the best of idea.”  
“Good quality and very quick.”  
“Advice adapted to MSF environment.”  
“Good way of communication.” |
| --- | --- | --- | --- |
| Other comments | | | Using email instead of the telemedicine system has delayed the expert advice  
A delay in getting the answer reduces the benefit of expert advice  
Headquarter's support is appreciated  
“Helpful to have opinions from different specialists on submission of one case”  
“It is great to be able to have expert advice in a very short time. It helps a lot to evaluate better and to make the right decisions for unknown diseases/ symptoms. Great, great thanks” |
Table 3. Characteristics of the cases

|                                      | With reports (n=41) | Without reports (n=160) | P-value |
|--------------------------------------|---------------------|-------------------------|---------|
| Median age, years (IQR)              | 28 (9-37)           | 22 (4-35)               | $Z=-1.5$, $P=0.13$ |

Table 5a. Data from a previous survey*. Responses from referrers

| Question to referrer | Yes / multiple choice | No | Unknown | Total answered | Skipped | Majority response |
|----------------------|-----------------------|----|---------|----------------|---------|------------------|
| Q37: Did you give the specialist any feedback about the patient? | 41% | 59% | - | 34 | 31 | No 59% |
| Q38: If no, was it because … | | | | | | |
| - patient lost to follow up | 14 | | | 37 | 43 | Lack of time 30% |
| - lack of time | 30 | | | | | |
| - forgotten to update | 24 | NA | NA | | | |
| - feeling it was not necessary | 16 | | | | | |
| - worse outcome or patient died | 3 | | | | | |
| - difficulties with Internet access | 14 | | | | | |
| Q39: Do you think that feedback about the patient is … | | | | | | |
| - optional | 14 | | | 27 | Desirable 43% |
| - desirable | 43 | NA | NA | | | |
| - necessary | 30 | | | | | |
| - mandatory | 14 | | | | | |
| Q40: in your opinion, is the patient likely to be available for follow-up in 2-4 months? | 22% | 46% | 32% | 37 | 27 | No 46% |
| Q41: in your opinion, when would it be relevant to give follow-up information? (i.e. completing a progress report) | | | | | | |
| - after 1 week | 53 | | | 38 | 28 | After 1 week 53% |
| - after 2 weeks | 24 | | | | | |
| - after 1 month | 18 | NA | NA | | | |
| - after 3 months | 5 | | | | | |
| - after 6 months | 0 | | | | | |
Table 5b. Data from a previous survey*. Responses from specialists

| Question to specialist | Yes / multiple choice | No | Unknown | Total answered | Skipped | Majority response |
|------------------------|-----------------------|----|---------|----------------|---------|------------------|
| Q37: Did you receive any follow-up information about this patient? | 8% | 92% | - | 63 | 36 | No 92% |
| Q38: Do you think that feedback about the patient is ... | | | | | | |
| -optional | 1 | | | | | |
| -desirable | 52 | | | | | |
| -necessary | 29 | | | | | |
| -mandatory | 18 | | | | | |

*Data from the MSF survey (50 questions) sent to 294 referrers and 254 specialists (in French and English) in December 2013.[2]
Table 6. Characteristics of those responding to all, some or none of the requests

|                                | All | Some | None |  \( P \)-value    |
|--------------------------------|-----|------|------|-------------------|
| No of referrers                | 6   | 17   | 25   |                   |
| No of referrals                | 15  | 388  | 415  | One-way ANOVA F=0.77, \( P=0.47 \) |
| Mean referrals per doctor      | 2.5 | 22.8 | 16.6 |                   |

**Sex**

|       | All | Some | None |  \( P \)-value    |
|-------|-----|------|------|-------------------|
| Male  | 2   | 2    | 3    | Males vs Females: \( \chi^2=0.5, P=0.77 \) \( P\)-value for trend=0.73 |
| Female| 1   | 3    | 3    |                   |
| Unknown| 3  | 12   | 19   | M/F vs Unknown: \( \chi^2=1.6, P=0.45 \) \( P\)-value for trend=0.25 |

**Country of referrers**

|                      | All | Some | None |  \( P \)-value |
|----------------------|-----|------|------|---------------|
| Low-income countries | 3   | 12   | 16   | \( \chi^2=5.1, P=0.08 \) \( P\)-value for trend=0.17 |
| Proxy countries      | 3   | 1    | 3    |               |

**MSF regions**

|      | All | Some | None |  \( P \)-value |
|------|-----|------|------|---------------|
| OCA  | 2   | 7    | 9    | \( \chi^2=7.5, P=0.48 \) |
| OCB  | 0   | 3    | 2    |               |
| OCBA | 0   | 2    | 7    |               |
| OCG  | 1   | 1    | 3    |               |
| OCP  | 3   | 4    | 4    |               |
