Abstract. In oncology, liquid biopsy is used in the detection of next-generation analytes, such as tumor cells, cell-free nucleic acids and exosomes in peripheral blood and other body fluids from cancer patients. It is considered one of the most advanced non-invasive diagnostic systems to enable clinically relevant actions and implement precision medicine. Medical actions include, but not limited to, early diagnosis, staging, prognosis, anticipation (lead time) and the prediction of therapy responses, as well as follow-up. Historically, the applications of liquid biopsy in cancer have focused on circulating tumor cells (CTCs). More recently, this analysis has been extended to circulating free DNA (cfDNA) and microRNAs (miRNAs or miRs) associated with cancer, with potential applications for development into multi-marker diagnostic, prognostic and therapeutic signatures. Liquid biopsies avoid some key limitations of conventional tumor tissue biopsies, including invasive tumor sampling, under-representation of tumor heterogeneity and poor description of clonal evolution during metastatic dissemination, strongly reducing the need for multiple sampling. On the other hand, this approach suffers from important drawbacks, i.e., the fragmentation of cfDNA, the instability of RNA, the low concentrations of certain analytes in body fluids and the confounding presence of normal, as well as aberrant DNAs and RNAs. For these reasons, the analysis of cfDNA has been mostly focused on mutations arising in, and pathognomonicity of, tumor DNA, while the analysis of cfRNA has been mostly focused on miRNA patterns strongly associated with neoplastic transformation/progression. This review lists some major applicative areas, briefly addresses how technology is bypassing liquid biopsy limitations, and places a particular emphasis on novel, PCR-free platforms. The ongoing collaborative efforts of major international consortia are reviewed. In addition to basic and applied research, we will consider technological transfer, including patents, patent applications and available information on clinical trials aimed at verifying the potential of liquid biopsy in cancer.

Abbreviations: CRC, colorectal cancer; HCC, hepatocellular carcinoma; CTCs, circulating tumor cells; cfDNA, circulating free DNA; cfRNA, circulating free RNA; miRNA or miR, microRNA; UTR, untranslated region; CDS, coding sequence; RISC, RNA-induced silencing complex; PCR, polymerase-chain reaction; RT, reverse transcription; qPCR, quantitative PCR; ddPCR, droplet digital PCR; WGS, whole genome sequencing; NGS, next generation sequencing; SPR-I, surface plasmon resonance imaging; SNPs, single nucleotide polymorphisms

Key words: liquid biopsy, circulating tumor cells, circulating free DNA, microRNA
1. The concept of liquid biopsy

Liquid biopsy investigates circulating tumor cells (CTCs) and/or cell-free nucleic acids in the peripheral blood of cancer patients (Fig. 1) and is considered one of the most advanced non-invasive diagnostic systems with which to obtain key molecular information relevant to clinical decisions and the practice of precision medicine (1-5). Diagnostic actions include, but are not limited to, early diagnosis, staging, prognosis, the prediction of therapeutic responses, and follow-up during therapeutic intervention (5-13). Historically, the applications of liquid biopsy for the characterization of cancer patients have been focused on CTCs (1). Looking for CTCs in peripheral blood has generated a very large number of reports focusing on diagnosis, prognosis and therapeutic management (6). The downstream characterization of CTCs, including the identification of possible therapeutic targets (e.g., mutations or other traits of aggressiveness) in this peculiar tumor cell subset not only has had a great impact on diagnosis and prognostication, but also has an impact on clinical protocols, charting the route to precision medicine (14-16). In this respect, an excellent example is colorectal cancer (CRC), one of the most frequent malignancies worldwide (17). As is known, the transformation of normal colonic epithelium into CRC is punctuated by the progressive accumulation of acquired genetic and epigenetic alterations deeply altering morphological parameters, cell growth potential and differentiation, and shutting down apoptosis. Recent basic and clinical research on CTCs in patients with CRC has underlined that the molecular detection of CTCs in peripheral blood is feasible, and their phenotypic characterization drives therapeutic protocols for tailored clinical interventions (18). Moreover, the real-time monitoring of CTCs in patients with CRC has been extensively applied for a better mechanistic understanding of the factors determining clinical outcome and the efficacy of therapeutic treatment, as well as the stability of therapeutic effects over time (18-21).

In addition to CTCs, the formal demonstration that free nucleic acids are present (although short-lived) in biological fluids (plasma being investigated by most authors), has led to the development of a large wealth of studies aimed at circulating DNA and RNA (22-24). This strategy, similar to CTC detection, allows for non-invasive diagnosis, and at the same time it represents a convenient method for directly interrogating tumor aberrations, addressing tumor heterogeneity and metastatic dissemination across multiple, longitudinally collected clinical specimens (6,7). On the other hand, this approach suffers from important drawbacks, i.e., the fragmentation of circulating free DNA (cfDNA), the instability of RNA, low analyte concentrations, and the confounding, variable presence of DNA and RNA from normal tissues and mutated cells from the hematopoietic compartment (clonal hematopoiesis) (25). Limitations notwithstanding, the analysis of cfDNA has successfully identified mutations arising in, and the pathognomonicity of, tumor DNA, while the analysis of circulating free RNA (cfRNA) has been mostly focused on miRNA patterns strongly associated with neoplastic transformation/progression (22). Examples of the detection of tumor cfDNA are presented in Table I (18-20,26-52), while examples of the detection of circulating miRNAs are presented in Table II (53-104).

2. Analytes in plasma: Examples of biomedical applications

Molecular targets: Cancer genetic aberrations. One of the most robust evidence supporting the application value of liquid biopsies is the detection of circulating genomic aberrations,

|----------------------------------------------------------------------------------|------------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------|
| Differential expression of microRNAs in plasma of patients with colorectal cancer: A potential marker for colorectal cancer screening | Colon cancer     | RT-qPCR array (miR-17-3p, miR-135b, miR-92 and miR-222)                                 | In the study, a panel of miRNAs were found to be upregulated both in plasma and tissue samples of patients with colorectal cancer                                                                              | Ng et al (61)   | 2009 |
| Serum microRNA panel as biomarkers for early diagnosis of colorectal adenocarcinoma | Colon cancer     | MiR-seq sequencing followed by (RT-qPCR) validation (miR-19a-3p, miR-223-3p, miR-92a-3p, and miR-422a) | A panel of four miRNA (miR-19a-3p, miR-223-3p, miR-92a-3p and miR-422a) with a high diagnostic accuracy of colorectal adenocarcinoma was identified. This miRNA panel could differentiate stage I/II colorectal adenocarcinoma from the controls | Zheng et al (62)| 2014 |
| Decreased plasma let-7c and miR-152 as non-invasive biomarker for non-small-cell lung cancer | Lung cancer      | RT-qPCR (let-7c and miR-152)                                                          | The expression of let-7c and miR-152 in plasma was found to be downregulated in patients with non-small cell lung cancer (NSCLC) and to be associated with the clinicopathological characteristics, such as histological classifications, differentiation status, lymph node metastasis and stage classifications | Dou et al (63)  | 2015 |
| Decreased circulating miR-375: A potential biomarker for patients with non-small-cell lung cancer | Lung cancer      | RT-qPCR (miR-375)                                                                     | Plasma miR-375 levels in patients with NSCLC were significantly decreased. In addition, patients with metastatic NSCLC had a lower plasma miR-375 expression than those with non-metastatic NSCLC, and had worse overall survival rates | Yu et al (64)   | 2014 |
| Digital PCR quantification of miRNAs in sputum for diagnosis of lung cancer       | Lung cancer      | Digital PCR and RT-qPCR (miR-31 and miR-210)                                          | Combined quantification of miR-31 and miR-210 copy number by using digital PCR in sputum was demonstrated useful for lung cancer diagnosis                                                                      | Li et al (65)   | 2014 |
| Five microRNAs in plasma as novel biomarkers for screening of early-stage non-small cell lung cancer | Lung cancer      | RT-qPCR (miR-20a, miR-145, miR-21, miR-223 and miR-221)                                | Five microRNAs (miR-20a, miR-145, miR-21, miR-223 and miR-221) were proposed as potential biomarkers for early-stage NSCLC                                                                                     | Geng et al (66)| 2014 |
| Serum microRNA signatures identified in a genome-wide serum microRNA expression profiling predict survival of non-small-cell lung cancer | Lung cancer      | Solexa sequencing and RT-qPCR (miR-486, miR-1, miR-30d and miR-499)                   | A panel of serum miRNAs was found altered by more than 5-fold between longer-survival and shorter-survival groups of lung cancer patients. The levels of four miRNAs (i.e., miR-486, miR-30d, miR-1 and miR-499) were significantly associated with overall survival | Hu et al (67)   | 2010 |
| Early detection of lung adenocarcinoma in sputum by a panel of microRNA markers   | Lung cancer      | RT-qPCR (miR-21, miR-486, miR-375 and miR-200b)                                       | In the sputum samples of lung adenocarcinoma patients, four miRNAs (miR-21, miR-486, miR-375 and miR-200b) were found able to distinguish patients with lung adenocarcinoma from normal subjects | Yu et al (68)   | 2010 |
| Title of the study                                                                 | Tumor type       | Assay and target miRNAs                                      | Major results                                                                                                                                                                                                 | Authors/(Refs.) | Year |
|--------------------------------------------------------------------------------|------------------|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|------|
| High expression of serum miR-21 and tumor miR-200c associated with poor prognosis in patients with lung cancer | Lung cancer      | miRNA microarray and RT-qPCR (miR-21)                      | Serum miR-21 was proposed as a biomarker for the diagnosis of NSCLC                                                                                                                                           | Liu et al (69)   | 2012 |
| A plasma miRNA signature for lung cancer early detection                        | Lung cancer      | qPCR-based TaqMan microRNA arrays (miR-126, miR-145, miR-210, and miR-205-5p) | A panel of 30 miRNAs displayed a significant differential expression level in the plasma of patients with lung cancer with respect to the cancer-free controls. A selected plasma miRNA signature (miR-126, 145, 210 and 205-5p) was proposed for lung cancer detection | Leng et al (70)  | 2017 |
| Direct serum assay for microRNA-21 concentrations in early and advanced breast cancer | Breast cancer    | RT-qPCR (miR-21)                                           | High circulating miR-21 concentrations were significantly associated with visceral metastasis in a multivariate analysis of breast cancer patients that included standard clinicopathological prognostic factors | Asaga et al (71) | 2011 |
| Circulating microRNAs in breast cancer and healthy subjects                    | Breast cancer    | RT-qPCR (miR-155)                                          | Women with progesterone receptor-positive tumors had higher circulating miR-155 levels than tumors that were negative for these receptors                                                                 | Zhu et al (72)   | 2009 |
| Circulating microRNAs as novel minimally invasive biomarkers for breast cancer  | Breast cancer    | RT-qPCR (miR-195 and Let-7a)                               | Cancer-specific miRNAs were detected and found to be significantly altered in the circulation of patients with breast cancer. Circulating levels of miR-195 and let-7a decreased in cancer patients post-operatively, to levels comparable with those of the control subjects | Heneghan et al (73) | 2010 |
| Aberrant plasma levels of circulating miR-16, miR-107, miR-130a and miR-146a are associated with lymph node metastasis and receptor status of breast cancer patients | Breast cancer    | miRNA microarray profiling and RT-qPCR (miR-16, miR-107, miR-130a and miR-146a) | Differential concentrations of plasma miR-16, miR-107, miR-130a and miR-146a in different breast cancer subtypes were found, suggesting a potential role of these miRNAs in breast cancer biology and tumor progression | Stückrath et al (74) | 2015 |
| Diagnostic and prognostic microRNAs in the serum of breast cancer patients measured by droplet digital PCR | Breast cancer    | Droplet digital PCR (miR-148b-3p, miR-652-3p and miR-10b-5p) | The serum levels of miR-148b-3p and miR-652-3p were significantly lower in the serum of breast cancer patients compared with the controls. In addition, higher serum levels of miR-10b-5p were associated with clinicobiological markers of a poor prognosis | Mangolini et al (75) | 2015 |
| A serum microRNA signature predicts tumor relapse and survival in triple-negative breast cancer patients | Breast cancer    | Genome-wide serum miRNA expression and RT-qPCR analyses (miR-18b, miR-103, miR-107, and miR-652) | The study identified a four-miRNA signature (miR-18b, miR-103, miR-107 and miR-652) that predicted tumor relapse and overall survival for patients with triple-negative breast cancer | Kleivi Sahlberg et al (76) | 2015 |
| Title of the study                                                                 | Tumor type | Assay and target miRNAs                                                                 | Major results                                                                                                                                                                                                 | Authors/(Refs.) | Year |
|----------------------------------------------------------------------------------|------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------|
| Comparison of a healthy miRNome with melanoma patient miRNomes: Are microRNAs   | Melanoma   | miRNome and custom qPCR array (miR-3201 and miR-122-5p)                                 | Results indicate a characteristic signatures with excellent prognostic scores only in patients with late-stage but not early-stage melanoma                                                                         | Margue et al (77) | 2015 |
| Serum-based miRNAs in the prediction and detection of recurrence in melanoma patients | Melanoma   | miRNA microarray and RT-qPCR (miR-15b, miR-150, miR-30d and miR-425)                    | The results of the study demonstrate that a panel of four serum miRNAs can improve melanoma patient stratification over stage                                                                                   | Fleming et al (78) | 2015 |
| A direct plasma assay of circulating microRNA-210 of hypoxia can identify early  | Melanoma   | RT-qPCR directly-in-plasma assay (RT-qPCR-DP) (miR-210)                                  | A RT-qPCR-DP performed to detect cf-miR-210 demonstrated that cf-miR-210 expression was significantly higher in patients with metastatic melanoma versus the healthy donor controls                                          | Ono et al (79)  | 2015 |
| systemic metastasis recurrence in melanoma patients                              |            |                                                                                         |                                                                                                                                                                                                             |                 |      |
| The prognostic and predictive value of melanoma-related microRNAs using tissue and serum: A microRNA expression analysis | Melanoma   | TaqMan assays and Fluidigm Real-time PCR (miR-16, miR-211, miR-4487, miR-4706, miR-4731, miR-509-3p and miR-509-5p) | In a minimally-invasive blood test, a seven-miRNA panel (MELmiR-7) detected the presence of melanoma with high sensitivity and specificity                                                                       | Stark et al (80) | 2015 |
| Serum microRNAs as biomarkers for recurrence in melanoma                         | Melanoma   | RT-qPCR (miR-150, miR-15b, miR-199a-5p, miR-33a and miR-424)                            | A signature of five miRNAs successfully classified melanoma patients into high and low recurrence risk groups                                                                                                  | Friedman et al (81) | 2012 |
| The circulating microRNA-221 level in patients with malignant melanoma as a new tumor marker | Melanoma   | RT-qPCR (miR-221)                                                                      | Patients with malignant melanoma had significantly higher miR-221 levels than the healthy controls. Furthermore, the miR-221 levels were significantly increased in patients with stage I-IV disease compared to those with melanoma in situ, and were associated with tumor thickness | Kanemaru et al (82) | 2011 |
| Identification of plasma microRNAs as new potential biomarkers with high diagnostic power in human cutaneous melanoma | Melanoma   | RT-qPCR (miR-149-3p, miR-150-5p and miR-193a-3p)                                        | Diagnostic impact of miRNAs was improved when considering the combination of miR-149-3p, miR-150-5p, and miR-193a-3p, discriminating between patients with melanoma and healthy controls                                      | Fogli et al (83) | 2017 |
| A combination of circulating miRNAs for the early detection of ovarian cancer      | Ovarian cancer | NGS miRNA sequencing followed by validation with RT-qPCR (let-7d-5p, miR-142-3p, miR-200a-3p, miR-26a-5p, miR-374a-5p, miR-766-3p, miR-130b-3p and miR-328-3p) | A novel predictive model was proposed based on a combination of 8 circulating serum miRNAs. This method was able to successfully distinguish patients with early-stage ovarian cancer from the healthy controls and those with benign tumors | Yokoi et al (84) | 2017 |
| Title of the study                                                                 | Tumor type     | Assay and target miRNAs                                      | Major results                                                                                                                                                                                                 | Authors/(Refs.) | Year  |
|----------------------------------------------------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------|
| Circulating miRNA landscape identifies miR-1246 as promising diagnostic biomarker in high-grade serous ovarian carcinoma: A validation across two independent cohorts | Ovarian cancer | miRNA microarray and droplet digital PCR (miR-1246, miR-595 and miR-2278)                                      | This study allowed the identification of circulating miRNAs with diagnostic relevance for high-grade serous ovarian carcinoma (HGSOC)                                                                                     | Todeschini et al (85) | 2017  |
| Expression of serum miR-200a, miR-200b, and miR-200c as candidate biomarkers in epithelial ovarian cancer and their association with clinicopathological features | Ovarian cancer | RT-qPCR (miR-200a and miR-200b, miR-200c)                                                                         | The expression levels of miR-200a and miR-200c were found to be significantly associated with disease progression, while miR-200a overexpression was found to be associated with tumor histology and the stage of epithelial ovarian cancer | Zuberi et al (86) | 2015  |
| Serum microRNA-144 as a novel biomarker in human ovarian cancer                                                                       | Ovarian cancer | RT-qPCR (miR-144)                                                                                               | Serum miR-144 levels could discriminate patients with malignant ovarian cancer from the healthy controls                                                                                                     | Liang et al (87) | 2015  |
| MicroRNA-200c and microRNA-141 as potential diagnostic and prognostic biomarkers for ovarian cancer                                   | Ovarian cancer | RT-qPCR (miR-200c and miR-141)                                                                                  | The results of the study suggested that serum miR-200c and miR-141 were able to discriminate patients with ovarian cancer from healthy controls. In addition, miR-200c and miR-141 may be predictive biomarkers for the prognosis of ovarian cancer | Gao and Wu (88) | 2015  |
| Urinary microRNA-30a-5p is a potential biomarker for ovarian serous adenocarcinoma                                                      | Ovarian cancer | miRNA microarray and RT-qPCR (miR-30a-5p)                                                                       | Results indicated an increase in miR-30a-5p levels in the urine of patients with ovarian serous adenocarcinoma. In parallel, the inhibition of miR-30a-5p suppressed the malignant phenotypes of ovarian cancer in vitro | Zhou et al (89)  | 2015  |
| Combining serum microRNA and CA-125 as prognostic indicators of preoperative surgical outcome in women with high-grade serous ovarian cancer | Ovarian cancer | RT-qPCR (miR-375, miR-34a-5p and miR-210)                                                                        | The combination of serum miR-375, miR-210 and CA-125 can discriminate healthy versus patients with high-grade serous ovarian cancer. The combination of miR-34a-5p and CA-125 was the strongest predictor of completeness of surgical resection | Shah et al (90) | 2018  |
| Serum microRNA characterization identifies miR-885-5p as a potential marker for detecting liver pathologies                            | Hepatocellular carcinoma | qPCR-based TaqMan microRNA arrays (miR-885-5p)                                                                   | miR-885-5p is significantly elevated in the sera of patients with liver pathologies, including hepatocellular carcinoma                                                                                       | Gui et al (91)  | 2011  |
| MicroRNA-500 as a potential diagnostic marker for hepatocellular carcinoma                                                           | Hepatocellular carcinoma | RT-qPCR (miR-500)                                                                                               | An increased amount of miR-500 was found in the sera of patients with hepatocellular carcinoma. In fact, miR-500 levels in the sera of patients with hepatocellular carcinoma returned to normal following surgical treatment | Yamamoto et al (92) | 2009  |
| Circulating microRNAs, miR-21, miR-122, and miR-223, in patients with hepatocellular carcinoma or chronic hepatitis                  | Hepatocellular carcinoma | RT-qPCR (miR-21, miR-122 and miR-223)                                                                           | Results indicated that serum miR-21, miR-122 and miR-223 were elevated in patients with hepatocellular carcinoma or chronic hepatitis and these miRNAs have strong potential to serve as novel biomarkers for liver injury, but not specifically for hepatocellular carcinoma | Xu et al (93)   | 2011  |
| Title of the study                                                                 | Tumor type                                      | Assay and target miRNAs                                                                 | Major results                                                                                                                                                                                                 | Authors/(Refs.) | Year  |

| Plasma microRNA panel to diagnose hepatitis B virus-related hepatocellular carcinoma | Hepatocellular carcinoma                        | miRNA microarray analysis and RT-qPCR (miR-122, miR-192, miR-21, miR-223, miR-26a, miR-27a and miR-801) | A microRNA panel that provides a high diagnostic accuracy of hepatocellular carcinoma was described                                                                                                                                  | Zhou et al (94)  | 2011  |
| Serum microRNA profiles serve as novel biomarkers for HBV infection and diagnosis of HBV-positive hepatocellular carcinoma | Hepatocellular carcinoma                        | NGS microRNA sequencing followed by validation with TaqMan probe-based RT-qPCR (miR-23b, miR-423, miR-375, miR-23a and miR-342-3p) | The study demonstrates that serum microRNA profiles can serve as non-invasive biomarkers for hepatitis B virus (HBV) infection and HBV-positive hepatocellular carcinoma diagnosis                                                                 | Li et al (95)    | 2010  |
| Circulating miR-106b-3p, miR-101-3p and miR-1246 as diagnostic biomarkers of hepatocellular carcinoma | Hepatocellular carcinoma                        | RNAseq and droplet digital PCR (ddPCR) (miR-106b-3p, miR-101-3p and miR-1246)            | Circulating miR-101-3p, miR-106b-3p and miR-1246, either individually or in combination, exhibit a considerable potential value as diagnostic biomarkers of hepatocellular carcinoma                                                                 | Moshiri et al (96) | 2018  |
| Combinations of serum prostate-specific antigen and plasma expression levels of let-7c, miR-30c, miR-141, and miR-375 as potential better diagnostic biomarkers for prostate cancer | Prostate cancer                                  | Quantitative PCR (let-7c, miR-30c, miR-141 and miR-375)                                 | Combinations of let-7c, miR-30c, miR-141, miR-375 and PSA obtained even better discrimination and could be more useful that prostate-specific antigen (PSA) alone as non-invasive diagnostic biomarkers for the screening of prostate cancer                                                | Kachakova et al (97) | 2015  |
| Changes in circulating microRNA levels associated with prostate cancer            | Prostate cancer                                  | miRNA microarray and RT-qPCR (miR-200b and miR-375)                                     | miR-200b and miR-375 levels are increased in the serum of patients with metastatic prostate cancer compared with patients with localized disease                                                                                                                                | Bryant et al (98) | 2012  |
| Circulating microRNAs are associated with docetaxel chemotherapy outcome in castration-resistant prostate cancer | Prostate cancer                                  | RT-qPCR microRNA array cards and RT-qPCR (miR-200 family and miR-17 family)              | The study has identified selected circulating microRNAs, notably those of the miR-200 and miR-17 families, associated with PSA response and/or overall survival in patients with castration-resistant prostate cancer                                                                 | Lin et al (99)   | 2014  |
| Circulating microRNAs 21 and 221 as biomarkers for early diagnosis of prostate cancer | Prostate cancer                                  | RT-qPCR (miR-21 and miR-221)                                                            | The study showed that serum miR-21 and miR-221 levels may be used as specific non-invasive molecular biomarkers for prostate cancer diagnosis                                                                                                                               | Kotb et al (100) | 2014  |
| Title of the study                                                                 | Tumor type       | Assay and target miRNAs                                      | Major results                                                                                                                                                                                                 | Authors/(Refs.)         | Year |
|----------------------------------------------------------------------------------|------------------|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|------|
| MicroRNA profiling in prostate cancer - the diagnostic potential of urinary miR-205 and miR-214 | Prostate cancer  | RT-qPCR microRNA array cards and RT-qPCR (miR-205 and miR-214) | miR-205 and miR-214 levels are downregulated in prostate cancer and may serve as a potential non-invasive molecular biomarker for prostate cancer                                                                 | Srivastava et al (101) | 2013 |
| Serum microRNA expression patterns that predict early treatment failure in prostate cancer patients | Prostate cancer  | miRNA microarray and RT-qPCR (miR-103, miR-125b and miR-222) | Altered content of miR-103, miR-125b and miR-222 in the serum of patients with prostate cancer was found to be associated with the outcome of clinical treatment                                                                 | Singh et al (102)      | 2014 |
| A study on circulating microRNAs identifies a new potential biomarker panel to distinguish aggressive prostate cancer | Prostate cancer  | RT-qPCR (miR-17, miR-192 and miR-181a)                      | The study demonstrates that a novel previously unreported circulating miRNA signature consisting of a combination of interacting miRNAs (miR-17/miR-192) and an independent miRNA (miR-181a) are capable of differentiating between aggressive and non-aggressive prostate cancer | Farran et al (103)     | 2018 |
| Different levels of serum microRNAs in prostate cancer and benign prostatic hyperplasia: Evaluation of potential diagnostic and prognostic role | Prostate cancer  | RT-qPCR (let-7c, let-7e, let-7i, miR-26a-5p, miR-26b-5p, miR-18b-5p and miR-25-3p) | let-7c, let-7e, let-7i, miR-26a-5p, miR-26b-5p, miR-18b-5p and miR-25-3p were able to discriminate between patients with prostate cancer from those harboring benign prostatic hyperplasia, both presenting altered PSA levels | Cochetti et al (104)   | 2016 |
mainly mutations. The topic is extensive, and is the subject of a number of excellent reviews. Therefore, in this review, we focus on very specific examples, particularly in early-stage tumors. KRAS mutations are a case in point, since they serve as an actionable marker for EGFR blockade therapy, are highly prevalent, and have been thoroughly investigated. For instance, Brychta et al compared plasma and paired tumor samples from early-stage pancreatic cancer patients (105) by chip-based digital PCR. Their major aim was to identify selected KRAS codon 12 mutations (G12D, G12V and G12C) in circulating tumor DNA (ctDNA). Remarkably, circulating KRAS mutations were demonstrated in 72% of the patients, were associated with tumor burden, and were undetectable in the healthy controls. This study supports the use of liquid biopsy for early cancer diagnosis. Other studies focusing on KRAS mutations in ctDNA were reported by Kinusaga et al (pancreatic cancer) (106), Couraud et al (lung cancer) (107), Perez-Carbonell et al (CRC) (108) and Case et al (lymphoblastic leukemia) (109). Table I summarizes the applicable examples of liquid biopsy for the identification of oncogene mutations, including the detection of EGFR mutations in the blood of lung cancer patients, now approved by regulatory bodies. These assays are of outmost interest and exemplify the profound difference between non-invasive liquid biopsy and invasive tumor tissue biopsy. Tissue biopsy may not reflect the genomic profile of the tumor in its entirety due to intra-tumor heterogeneity, multiple foci poorly accessible to sampling, and/or changes occurring during tumor development and/or therapy. On the contrary, the non-invasive liquid biopsy of plasma, urine or saliva samples may more effectively recapitulate the mutational complexity of the many populations (cryptic and clinically evident) accounting for tumor burden in a given patient. This makes liquid biopsy particularly suitable to identify truncal aberrations that, when targeted, may result in a considerably greater systemic clinical benefit, as compared to targeting site-specific aberrations (Lin et al, 2015) (110).

Molecular targets: Gene methylation. A variation on the theme is to look at non-mutational events marking the cancer genome. Particularly relevant in this context is DNA methylation. It has been known for quite some time that tumor progression is associated with the abnormal methylation of cancer genes. Both hypomethylation and hypermethylation have been reported. Most often, the specific DNA hypermethylation of tumor suppressor genes is observed in the context of widespread DNA hypomethylation. Since aberrant DNA methylation at specific promoter regions is a defined molecular feature of cancer, ctDNA methylation has been developed into a very promising molecular marker. DNA methylation is to date one of the preferred consensus circulating biomarkers in pre-symptomatic and symptomatic patients with CRC. This has been discussed by Warton et al (111) and by Mitchell et al (112), who have considered methylation-specific PCR assays as a novel approach for the assessment of low levels of DNA methylation in 29 regions of 17 genes. Eight differentially-methylated regions (DMRs) residing in the BCAT1, GRASP, IKZF1 and IRF4 genes, exhibited low positivity in the plasma of healthy subjects and high positivity (≥59%) in ctDNA from colonoscopy-confirmed patients with CRC.

Molecular targets: Circulating microRNAs. MicroRNAs (miRNAs or miRs) are a family of small (19 to 25 nucleotides in length) non-coding RNAs which play important roles in controlling post-transcriptional gene expression. Regulatory miRNAs reduce protein synthesis through selective interactions with complementary sequences of target messenger RNAs (mRNAs) (113,114). Single or multiple miRNAs can be targeted at their 3′ untranslated region (UTR), coding sequence (CDS), 5′UTR sequences, and it is calculated that >60% of human mRNAs are miRNA targets (114). The miRNA/mRNA interaction occurs at the level of RNA-induced silencing complex (RISC) and is associated with the repression of translation or mRNA degradation, depending on the levels of complementarity with nucleotide sequences on the target mRNAs (115-118). Since their discovery and first characterization, the number of human miRNAs identified and deposited in the miRBase databases (miRBase v.22, www.mirbase.org) has been steadily increasing and is now >2,500 (119,120). Research on miRNAs has confirmed the complexity of this expanding miRNA/RNA network (117-122).

Alterations in miRNA expression have been associated with different human diseases. The guided alteration of specific miRNAs may potentially lead to innovative therapeutic protocols (123,124). miRNAs function both as tumor promoters (oncomiRNAs and metastamiRNAs) and tumor suppressors (125,126), depending on their regulatory preference for oncoproteins with opposing influences on cancer cells. Based on this, it is unsurprising that circulating cell-free miRNAs have been actively investigated as liquid biopsy analytes. OncomiRNAs are abundant in several extracellular body fluids (127-132), where they are protected and stabilized by exosome-like structures and small intraluminal vesicles produced by a variety of cells (including cancer cells) (127).

Hence, elevated levels of several miRNAs (including miR-221, miR-222, miR-141, miR-92a, miR-21, miR-155, miR-506 and miR-4316, miR-4772 and miR-29a) are present in the blood from patients with CRC (53-62,133,134) and may contribute to the diagnosis and prognosis of patients with CRC (134). Furthermore, miRNAs may aid in the monitoring of therapeutic approaches. For instance, Ogata-Kawata et al reported that serum exosomal miRNA levels (let-7a, miR-1229, miR-1246, miR-150, miR-21, miR-223 and miR-23a) were higher in patients with CRC than in the controls, that this abnormally high levels were already detectable at early disease stages, and that they were significantly downregulated following surgical resection (60).

3. Technologies

In order to identify specific DNA mutations and quantify miRNA levels in plasma and other body fluids of cancer patients, several types of technologies for DNA/RNA analysis have been proposed. For cfDNA analysis, the golden standards are possibly quantitative PCR (qPCR) and digital PCR; however, several additional technologies have been proposed (Table I), such as polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP) analysis (27), multiplex digital PCR (dPCR), allele-specific qPCR (18,39), whole genome sequencing (WGS) (28), cancer personalized profiling deep sequencing (Capp-Seq) (30),
methyltransferase-specific PCR (31,37,44), the Discrimination of Rare EpiAlleles by Melt qPCR (DREAMing) (33), bidirectional pyrophosphorolysis-activated polymerization (bi-PAP) real-time PCR (40) and tagged-amplicon deep sequencing (TAam-Seq) (42). For miRNA analysis, qPCR and reverse transcription (RT)-PCR (53-58), NGS RNA sequencing (63), miRNA microarray analysis (60) and digital PCR (65) are the most commonly used technologies (Table II).

A common step, and under many respects a complication of all the above-mentioned technologies, is the need to amplify the minute amounts of target analytes by an enzymatic reaction with DNA modifying enzymes, most often Taq polymerase and its derivatives. Biosensing platforms hold great promise for the simple and rapid detection of cfDNA and cfRNA (135), since they skip this time-consuming, analyte-dependent, PCR amplification step. Novel PCR-free biosensing approaches are able to detect KRAS and BRAF mutations in the serum of patients with lung cancer and melanoma (136).

Digital PCR (137) is based on the limiting dilution of DNA, and single molecule detection to identify and quantify the target mutated DNA in a given sample (138,139). This experimental approach is very useful for the identification of rare variants and in non-invasive diagnosis on peripheral blood, since only a small concentration of template is required for the analysis. Next generation sequencing (NGS) is a high throughput DNA sequencing technology which allows for the analysis, in a single reaction, a large variety of different DNA aberrations across multigene panels (140,141), although comprehensiveness may somewhat detract from sensitivity. Different commercial NGS platforms are available, such as Genome Analyzer and HiSeq 2000 (Illumina), HeliScope (Helicos BioSciences), SOLID and Ion Torrent (Life Technologies), Roche/454 (Roche). In these instruments, templates, primers or polymerase enzymes are immobilized on a solid support or on microbeads before sequencing, allowing the process of millions of microreactions carried out in parallel on each spatially distinct template.

However, as already pointed out, several challenges are related to liquid biopsy, the most important of which is the amount of target molecules to be detected and quantified. As far as cfDNA detection is concerned, these target molecules are so diluted by normal DNA that existing sequencing methods, such as Sanger sequencing, were not considered sufficiently sensitive to detect tumor-associated DNA mutation. As shown in Table I, the most commonly used approach was based on mutation-specific PCR, a technology proven to exhibit sufficient specificity and sensitivity allowing for the detection of the weak tumor signal present in the patient's circulation. This technology may be associated with important drawbacks when the quantification of miRNAs is considered, suffering from biases in the template-to-product ratios of the amplified target sequences (141). In addition, differential RT efficiency on different miRNA targets may also introduce variability when miRNA patterning is considered. Once again, PCR-free detection strategies are of great interest (142,143).

4. Experimental model systems for technological validation

Liquid biopsy is a complex strategy requiring pre-analytical steps, post-analytical optimization, and the careful selection of optimal analytes for specific biological queries. In vivo model systems may be very useful in addressing and isolating these numerous individual variables (that are both technical and biological), and validate complex multi-step approaches. It is surprising, in this respect, that only few reports are available focusing on the use of animal models. For example, Garcia-Olmó et al directly compared the tumor ctDNA concentration and the number of circulating cancer cells in rats with xenograft tumors during the spread of CRC (144). Of note, they found that high ctDNA levels preceded the presence of CTCs. Rago et al (145) developed an elegant and highly sensitive qPCR test to quantify ctDNA by targeting LINE-1 in mouse xenografts, demonstrating that this experimental system enables the monitoring of systemic tumor burden and close examination of the therapeutic management on a variety of animal tumor models. These studies demonstrate the importance of ctDNA and how it intertwines with CTCs. In a more recent study, Thierry et al (146) evaluated the relative quantitative contributions of non-tumor, tumor and mutated ctDNA, as well as ctDNA integrity, in an animal model. In this case, they found differences between patients with CRC and nude mice xenografted with human colon cell lines, suggesting that further research is necessary to validate in vivo model systems based on mice xenografted with tumor cell lines.

As for miRNAs, different independent studies have firmly demonstrated that miRNAs released into the circulation by tumor xenografts are distinct from ‘background’ mouse miRNAs. This is a key point, since pre-existing miRNAs present in mouse body fluids may be a powerful confounding parameter, possibly altering conclusions and implications of any circulating miRNA signature. In this respect, the use of laboratory mouse strains has the advantage that it sets a ‘background’ mouse miRNA pattern that is stable and easily quantifiable. Mitchell et al demonstrated that several miRNAs originating from xenografted human prostate cancer cells are present in the circulation (one of the most interesting being miR-141), and are readily measured in plasma, allowing a clear distinction between tumor-xenografted mice and controls (147). Sethi et al (148) performed global miRNA profiling and identified a set of miRNAs exhibiting significantly altered serum levels in transgenic mice bearing prostate adenocarcinoma tumors. Among the most interesting miRNAs, they focused their attention on miR-141 and miR-375. Waters et al observed a complex miRNA dysregulation in the circulation of athymic nude mice subcutaneously injected with MDA-MB-231 cells. Some miRNAs (such as miR-10b) were undetectable in the circulation, some others (miR-195 and miR-497) were significantly decreased, the miR-221 content was not altered, and a positive correlation was observed between miR-497 and miR-195. That study highlighted the distinct roles of miRNAs in the circulation and in disease dissemination and progression, all of which may be candidates as molecular targets for diagnosis, as well as for systemic therapy (149). More recently, Greystoke et al developed a robust protocol that allowed for the specific profiling of human tumor miRNAs in microliters of tail vein plasma (150). In a recent study, Gasparrillo et al presented the analysis of KRAS variants and the content of miR-141, miR-221 and miR-222 in mice xenografted with colon cancer cell lines (151). These results support the existence of multiple, finely tuned (non-housekeeping) control
gateways that selectively regulate the release/accumulation of distinct ctDNA and miRNA species in culture and tumor xenograft models (Fig. 2).

5. Specific biomedical applications

ctDNA and miRNAs find application in a variety of clinical cancer settings.

Early diagnosis. Liquid biopsy for early lung cancer detection has been reviewed by Hofman (152) and by Pérez-Ramírez et al (153). Coupled with thoracic imaging, liquid biopsy is a powerful diagnostic tool, and potentially provides surveillance recommendations for high-risk populations without a detectable nodule. In a study on patients with CRC, Bedin et al (154) examined a large cohort of patients with CRC in comparison to healthy subjects and patients with adenomatous lesions. In
their study, the presence and integrity of plasma cfDNA and the methylation profile of two gene promoters were evaluated. The cfDNA concentration and cfDNA integrity were found to be increased in patients with CRC, and were associated with a poor prognosis. A lower extent of DNA methylation was observed in cfDNA as compared to tissue DNA.

With respect to alterations affecting cancer drivers, a high prevalence was previously described by Allenson et al of mutant KRAS in circulating exosome-derived DNA from patients with early-stage pancreatic cancer (155). One very interesting observation of their study was that exosomes from viable cancer cells may reflect a different biology than cfDNA shed from dying tissues, including normal tissues. The information that the analyzed ctDNA is derived from actively metabolizing cancer cells with invasive potential, and not from normal cells, is certainly a crucial issue for early diagnosis. In this respect, Allenson et al (155) observed that the size of ctDNA differs depending on whether it is released from necrotic and dying cells or from live cells. The former is contained in cfDNA, the latter is included in the exosome-DNA fraction. The conclusion of their study was that exosomes should be considered as distinct sources of tumor DNA that may be complementary to other liquid biopsy DNA sources. In addition, circulating mutant KRAS was found in a minority of healthy samples, suggesting that care should be exercised when proposing liquid biopsy as a broad cancer-screening method.

As far as miRNA-based early diagnosis, an interesting study by Shimomura et al employed a highly sensitive microarray assay for the evaluation of serum miRNA expression profiles (156). In this large study, a total of 1,280 serum samples from patients with breast cancer were tested. In addition, 2,836 serum samples were obtained from non-cancer controls, 451 from patients with other types of cancers, and 63 from patients with non-breast benign diseases. The expression of miRNAs was compared between breast cancer and non-breast cancer patients. The conclusion was that a set of five miRNAs (miR-1246, miR-1307-3p, miR-4634, miR-6861-5p and miR-6875-5p) discriminated breast cancer from healthy control and non-breast cancer patients.

Staging and prognosis. Schröck et al (157) presented a study on free-circulating methylated DNA for the diagnosis, staging and prognosis of head and neck squamous cell carcinoma patients. In their study, the DNA methylation of two genes [short stature homeobox 2 (SHOX2) and septin (Sept9)] was quantified in plasma before treatment, and thereafter longitudinally during follow-up. The methylation levels were associated with the tumor and nodal category, and increased DNA methylation levels were associated with a shorter survival. On the whole, the data independently obtained in different laboratories support the hypothesis that the testing of DNA methylation in plasma is a powerful diagnostic tool for staging, risk stratification and disease monitoring. Patients with initially high biomarker levels may benefit from intensified treatment and surveillance. The marker-driven, timely detection of recurrent/metastatic disease may guide successive lines of treatment, thereby improving patient outcomes.

Therapeutic outcome. One example demonstrating the possible role of liquid biopsy in predicting therapeutic outcome has been reported by Quandt et al (158) who discussed how information obtained from liquid biopsies may contribute to the clinical decision-making process for cancer immunotherapy. This issue is of great interest since the application of immune checkpoint blockade over the past decade has revolutionized the treatment of a number of malignancies, leading to significantly improved survival. In this context, liquid biopsies are proposed to monitor treatment efficacy, acquired resistance to therapy and assign prognosis. A second example was published by Goodall et al (159) on cfDNA to guide prostate cancer treatment with poly(ADP)-ribose polymerase (PARP) inhibition. They reported whole exome sequencing of serial cfDNA samples collected during the treatment of patients with prostate cancer with the PARP inhibitor, olaparib. Decreases in the cfDNA concentration were found to be associated with a favorable outcome. All tumor tissue somatic DNA repair mutations were detectable in cfDNA, and allelic frequencies of somatic mutations decreased selectively in responding patients. At disease progression, following response to olaparib, multiple sub-clonal aberrations and somatic mutations in DNA repair genes (BRCA2 and PALB2) emerged as mechanisms of resistance. These data support the role of liquid biopsies as predictive, prognostic, response and resistance biomarkers in prostate cancer.

Final considerations on the management of cancer patients, follow-up and treatment monitoring. The results obtained thus far have indicated that liquid biopsy considerably affects systemic cancer therapy in metastatic cancer, due to the relevant information it provides to the medical oncologist. This is expected to improve key clinical parameters, such as patients overall survival and quality of life. This should be considered a major advantage of liquid biopsy (as outlined in Fig. 3), since the tissue biopsy of metastatic foci, is not only invasive, but is limited to certain locations, does not reflect clonal heterogeneity and multiple biopsies (even assuming they are feasible) may not be easily accepted, and may engender doubts and contradictory diagnostic reports. Along this line, a droplet digital PCR (ddPCR) study by He et al (160) on 120 patients with a diverse EGFR mutational status supported an association between liquid biopsy and outcome. Of note, it was found that the mutant signature was stable and marked dynamic changes during the treatment allowing efficient and continuous disease profiling, which is expected to greatly facilitate the clinical decision-making process.

6. PCR-free detection strategies

Despite the fact that the majority of the analytical technologies are based on PCR and RT-PCR (see the Technologies section above and Tables I and II), PCR-free methods have attracted great interest in biomedicine. In fact, several articles have been published dealing with PCR-free methods for the detection of point mutations. In addition to the already cited limitation of PCR-based approaches, the need for repeated steps involving heating and cooling is an important limitation of all the PCR-based technologies, particularly when the PCR steps for the amplification of nucleic acids are associated with procedures performed in microfluidic-based devices (143,161-164). Several alternative isothermal-amplification methods (which
do not require thermal cycling) have been developed to overcome this limitation, including nucleic-acid-sequence-based polymerization (NASBA), loop-mediated amplification (LAMP), helicase-dependent amplification (HAD), rolling-circle amplification (RCA), recombinase-polymerase amplification (RPA) and multiple-displacement amplification (MDA) (142). Recently, isothermal circular-strand-displacement polymerization (ICSPD) has emerged as a novel and promising method for nucleic-acid amplification and detection (163). Finally, promising opportunities are offered by selected isothermal amplification approaches that are based on a simple design of the amplification process and can be integrated in microfluidic devices (142). Such methods allow for the minimization of potential sample contaminations and minimize the sample volume required for the analysis (143).

In this respect, the direct detection of point mutations in non-PCR-amplified human genomic DNA has been recently demonstrated by surface plasmon resonance imaging (SPR-I). Attomolar concentrations of target genomic DNA have been detected, demonstrating the ultra-sensitivity of the new method and its potential application in several biomedical fields, including liquid biopsy methods (164).

7. Patents and clinical trials on liquid biopsy and ultrasensitive detection systems

Tables III (165-173) and IV (174-182) summarize patents and patent applications related to the development of liquid biopsy protocols in cancer diagnosis. It is of interest to go through the claims of these patents, as they reflect the consideration given to liquid biopsy by a large part of the scientific community. Several patents build on the concept that mutations of tumor-associated genes (present in cfDNA from body fluids) and/or miRNA profiles are prognostic (associated with outcome), and/or predictive (associated with susceptibility to specific treatments). Examples of patents related to cfDNA and miRNAs are numerous and have steadily increased over the years. In fact, CTC counts, and molecular signatures originating from or associated with CTCs have been shown to be associated with conventional cancer molecular genotyping in tissues.

For instance, in EP2426217A1 (166) a method is described for detecting cell free nucleic acids, preferably cfDNA in a body fluid sample from an individual or a patient. A general claim, present in many other similar patent applications, relates to a method that comprises the step of accurately and sensitively determining the concentration of cell free nucleic acid and/or the index of integrity of said cell free nucleic acid and/or or the determination of the presence of genetic polymorphisms [such as known single nucleotide polymorphisms (SNPs) or mutations]. The invention encompasses also a method to discriminate body fluid individuals where cfDNA are highly released. The majority of the approaches described in Table III have been validated on a variety of body fluids (urine, saliva, serum, plasma, bone marrow, lymphatic fluid, lacrimal fluid, serous fluid, peritoneal fluid, pleural fluid, ductal fluid from breast, gastric juice, or pancreatic juice) and cancers [breast cancer, CRC, periampullary cancer, melanoma, prostate cancer, gastric cancer, leukemia/lymphoma, renal cell carcinoma, hepatocellular carcinoma (HCC), neural-derived tumor, head and neck cancer, lung cancer, or sarcoma]. In addition to SNPs and tumor-associated mutations (presented in EP2426217A1, US7718364B2, WO2016168844A1 and
### Table III. Examples of patents and patent applications on circulating free DNA (cfDNA) based liquid biopsy in oncology.

|-----------------------------------|------------|--------------------------------------------|--------------------------------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| US7718364B2 (168)                 | May 18, 2010 | DNA markers for management of cancer       | Hoon DSB (Los Angeles, CA, USA) and Taback B (Santa Monica, CA, USA) | John Wayne Cancer Institute (Santa Monica, CA, USA) | A method is provided for assessing allelic losses and hypermethylation of genes in the CpG tumor promoter region on specific chromosomal regions in cancer patients, including patients with melanoma, neuroblastoma breast, colorectal and prostate cancer. The method relies on the evidence that free DNA and the hypermethylation of genes in the CpG tumor promoter region may be identified in the bone marrow, serum, plasma and tumor tissue samples of cancer patients. | A method of detecting DNA markers in a sample, comprising: i) Providing a cell-free bone marrow sample from a subject; and ii) detecting one or more DNA markers in the sample, wherein the DNA markers are indicative of LOH or DNA hypermethylation, or the DNA markers are indicative of DNA mutation in KRAS or BRAF gene. |
| EP2483426A4 (169)                 | April 10, 2013 | Method for analysis of DNA methylation profiles of cell-free circulating DNA in bodily fluids | Cortese R and and Petronis A | Centre for Addiction and Mental Health | This invention regards a variety of methods and compositions for obtaining epigenetic information, such as DNA methylation patterns, through the preparation, amplification and analysis of Methylome libraries. In several aspects of the present invention, there are methods based on methylation-dependent enrichment or depletion of genomic DNA isolated from cellular and cell-free sources. In additional embodiments, there are methods and compositions for single-step high throughput preparations of Methylome libraries. | Genomic regions that are actively expressed within cells are often found to be hypomethylated in the promoter and upstream coding regions. By contrast, downstream regions are typically kept hypermethylated in actively transcribed genes, but become hypomethylated in cancer. On the other hand, the hypermethylation of tumor suppressor genes has been associated with the development of many forms of cancer. |

|------------------------------------|------|-------|----------------------|---------------------------------|----------------------------|-----------------------------------------------|
| US20140303008A1 (170)              | October 9, 2014 | Colorectal cancer associated circulating nucleic acid biomarkers | Schutz E (Göttingen, Germany), Beck J (Göttingen, Germany) and Urnovitz H (San Jose, CA, USA) | Chronix Biomedical | The methods consist of detecting biomarkers in body fluids of patients with colorectal cancer. The proposed biomarkers are polynucleotide fragments, e.g., DNA fragments, that are present at an elevated level in blood, e.g., in a serum or plasma sample, of a colorectal cancer patient in comparison to the level in blood, e.g., a serum or plasma sample, obtained from a normal individual who does not have colorectal cancer | This invention provides methods and reagents for diagnosing colorectal cancer that are based on the detection of biomarkers in the circulating nucleic acids from a patient to be evaluated |
| WO2016168844A1 (171)              | October 20, 2016 | Quality assessment of circulating cell-free DNA using multiplexed droplet digital PCR | Murtaza M and Contente-Cuomo T | The Translational Genomics Research Institute | This invention provides a method of determining integrity and/or quantity of cfDNA in a biological sample. The present invention also provides methods for generating a library with the cfDNA for sequencing and analysis | This invention provides methods for the diagnosis of cancer that are based on the release of cfDNA from the patient to be evaluated |
| WO2006128192A2 (172)              | November 30, 2006 | Use of free circulating DNA for diagnosis, prognosis, and treatment of cancer | Hoon DSB, Umetani N and Sunami E | John Wayne Cancer Institute | This invention provides a method to determine the sequence integrity of circulating DNA using quantitative real-time polymerase chain reaction (qPCR), microarrays, probes by blotting, or gel electrophoresis based, colorimetric detection assays such as ELISA, chemiluminescence methods, digital detection, and mass spectrometry (MALDI-TOF). The methylation integrity of the circulating DNA may be detected and quantified, e.g., using quantitative analysis of methylated alleles (QAMA), qPCR, gel electrophoresis, microarrays, mass spectrometry, digital detection, or colorimetric based methods. The total amount of the circulating DNA is indicated by the amount of ALUs and LINEs | The method comprises identifying a subject suffering from or at risk for developing cancer, obtaining a body fluid sample from the subject, and determining the sequence integrity of circulating DNA. The body fluid sample may be, a sample of serum, plasma, urine, saliva, bone marrow, lymphatic fluid, lacrimal fluid, serous fluid, peritoneal fluid, pleural fluid, ductal fluid from breast, gastric juice, or pancreatic juice. |

| US20160053301A1 (173)             | February 25, 2016 | Methods for quantitative genetic analysis of cell free DNA | Raymond CK, Lim LP and Armour CD, Resolution Armour CD Bioscience Inc., Resolution Armour CD Bioscience Inc. | The invention provides a method for the genetic analysis of individuals that reveals both the genetic sequences and chromosomal copy number of targeted and specific genomic loci in a single assay. The present invention further provides methods for the sensitive and specific detection of target gene sequences and gene expression profiles. The key objective of the method is performing a quantitative genetic analysis of one or more target genetic loci in the cfDNA library clones. | A cancer may be a breast cancer, colorectal cancer, periampullary cancer, melanoma, prostate cancer, gastric cancer, leukemia/lymphoma, renal cell carcinoma, hepatocellular carcinoma, neural-derived tumor, head and neck cancer, lung cancer, or sarcoma. The cfDNA is isolated from a biological sample selected from the group consisting of: amniotic fluid, blood, plasma, serum, semen, lymphatic fluid, cerebral spinal fluid, ocular fluid, urine, saliva, stool, mucous, and sweat. The analyzed genetic lesion comprises a genomic rearrangement that fuses the 3' coding region of the ALK gene to another gene (for example the EML4 gene). |

| US9896683B2 (174)                  | February 20, 2018 | Isolating circulating microRNA (miRNA)                               | Ambros V, Lee R and Fusco AP       | Firefly Bioworks University of Massachusetts (UMass) | Methods for isolating circulating small RNAs, e.g., miRNAs from plasma samples, e.g., that involve the use of an alkaline phenol:chloroform extraction, and methods of use thereof, including for the detection, prognosis, and/or monitoring of disease in a subject | The methods include providing a first sample comprising plasma or serum of the human subject; detecting a level of one or more circulating miRNAs; providing a second sample comprising plasma or serum at a second time point; detecting a level of the one or more circulating miRNAs in the second sample using the same method; and comparing the level of the miRNA in the first sample to the level of the miRNA in the second sample. |
| US8216784B2 (175)                  | July 10, 2012  | Cancer-derived microvesicle-associated microrna as a diagnostic marker | Taylor DD and Gercel-Taylor C       | University Of Louisville Research Foundation, Inc. | A method for assessing the presence of one or more microRNAs in microvesicles, comprising isolating a population of cancer-derived microvesicles from a biological sample using a microvesicle surface marker, isolating microRNA from said population of cancer-derived microvesicles and determining a presence of one or more microRNAs in said cancer-derived microvesicles. | The method can be applied to a variety of biological including milk, blood, serum, plasma, ascites, cyst fluid, pleural fluid, peritoneal fluid, cerebral spinal fluid, tears, urine, saliva, sputum, or combinations thereof. The method is based on the analysis of one or more microRNAs selected from the group consisting of miR-21, miR-141, miR-200a, miR-200b, miR-200c, miR-203, miR-205 and miR-214. |
Table IV. Continued.

| Patent or patent application/(Refs.) | Date       | Title                                               | Inventors                      | Original assignee or co-assignee | Short description (claims) | Validity, significance and biomedical applications |
|-------------------------------------|------------|-----------------------------------------------------|--------------------------------|--------------------------------|----------------------------|---------------------------------------------------|
| EP2806273B1 (176)                   | September 6, 2017 | Exosome-associated microRNA as a diagnostic marker | Taylor DD and Gercel-Taylor C | University of Louisville Research Foundation, Inc. | A method is described for assessing the presence of one or more microRNAs in microvesicles, comprising isolating a population of microvesicles from a biological sample using a microvesicle surface marker, isolating microRNA from said population of microvesicles and determining a presence of one or more microRNAs in said microvesicles. | As one example, ovarian cancer remains the sixth most common type of cancer affecting women worldwide, causing approximately 125,000 deaths annually. Since long-term survival has not altered significantly over the past few decades, the best prospects for further improvement of ovarian cancer survival reside in early diagnosis. |
| US20130324589A1 (177)               | December 5, 2013 | Methods for Diagnosing Pancreatic Cancer Using MicroRNAs | Croce CM, Calin GA and Volinia S | Ohio State University | Described herein are methods for diagnosing pancreatic cancer using miRNAs. Also described are methods and compositions for the diagnosis and treatment of solid cancers. Methods of identifying inhibitors of tumorigenesis are also provided. | |
| EP3011058A1 (178)                   | April 27, 2016 | Circulating microRNA based cancer biomarkers         | Ditzel H and Kodahl AR         | Syddansk Universitet | A method of diagnosing whether a subject has, or is at risk of developing cancer, such as breast cancer or colorectal cancer, or monitoring the progression or regression of said cancer in a subject. The method comprises measuring the level of at least one miR-365, miR-425, miR-143, miR-133a, miR-19a, and miR-18a, such as the combination of miR-365, miR-425, miR-143, miR-133a, miR-19a and miR-18a. | The alteration in the level of the miRNA in the test sample (such as serum, plasma, or full blood), relative to the level of a corresponding miRNA in a control sample, is indicative of the subject either having, or being at risk for developing, cancer, or respond to any treatment of the cancer. |
| Patent or patent application/(Refs.) | Date       | Title                                                                 | Inventors                                                                 | Original assignee or co-assignee                   | Short description (claims)                                                                 | Validity, significance and biomedical applications |
|------------------------------------|------------|----------------------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------|---------------------------------------------------------------------------------------------|--------------------------------------------------|
| EP3138926A3 (179)                  | April 5, 2017 | MicroRNA signatures in human ovarian cancer                           | Croce CM                                                                 | The Ohio State University Research Foundation    | The present invention provides novel methods for the diagnosis of ovarian cancer using at least one miR selected from miR-200b, miR-141, miR-199a, miR-140, miR-145 and miR-125b, miR-200c | The invention also provides methods of identifying anti-ovarian cancer agents and a kit for detecting ovarian cancer |
| EP2944700B1 (180)                  | October 18, 2017 | Plasma microRNAs for the detection of early colorectal cancer       | Gironella I Cos M, Lonzano-Salvatella JJ, Castells I Garangou A and Giraldez MM | Hospital Clínico de Barcelona, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD) | The method comprises the following steps: i) Measuring an overall expression pattern or level of miRNAs obtained from one or more biological samples (wherein at least those miRNAs are miR18a and optionally miR19a and miR19b and miR15b); ii) comparing the overall expression pattern of miRNAs from the biological sample of the subject suspected of suffering from advanced colorectal adenomas or colorectal neoplasia with the overall expression pattern of the miRNAs from a biological sample of a normal subject | The present invention refers to a method for the diagnosis or detection of advanced colorectal adenomas and optionally colorectal neoplasia in a subject |
| US9388470B2 (181)                  | July 12, 2016 | Serum or plasma microRNA as biomarkers for non-small cell lung cancer | Zhang C, Zeng K, Zhang J, Ba Y, Chen X and Li H                          | Micromedmark Biotech Co. Ltd.                    | The present invention provides non-small cell lung cancer markers and the use thereof in diagnosing and monitoring diseases in vitro. The non-small cell lung cancer markers include at least one of the 26 selected detectable mature miRNAs existing stably in human serum or plasma. The invention also provides probe combinations, a kit and biochip for detecting the non-small cell lung cancer markers | The method in the present invention enables extensive detection spectrum, high sensitivity, low cost, convenient sample taking and preservation; it can be applied the general survey of disease, solves issues with the low specificity and sensitivity encountered with previous single markers, and significantly increases the clinical detection rate of diseases |
US20160053301A1) (166,168,171,173), another interesting marker is DNA methylation. In US7718364B2 (168), a method is provided for assessing allelic losses and the hypermethylation of genes in the CpG tumor promoter region on specific chromosomal regions in patients suffering from melanoma, neuroblastoma, breast, colorectal and prostate cancer. The method is based on the evidence that free DNA and hypermethylation of genes in the CpG tumor promoter region may be identified in the bone marrow, serum, plasma and tumor tissue samples of cancer patients. Table III lists examples of patents and patent applications focusing on cfDNA analysis in the body fluids of cancer patients.

As far as miRNAs are concerned, US8216784B2 (175) and EP2806273B1 (176) deal with cancer-derived microvesicle-associated miRNAs as a diagnostic marker for the detection of cancer. The method is based on the analysis of one or more miRNAs selected from a group comprising miR-21, miR-141, miR-200a, miR-200b, miR-200c, miR-203, miR-205 and miR-214. The method can be applied to a variety of biologicals, including milk, blood, serum, plasma, ascites, cyst fluid, pleural fluid, peritoneal fluid, cerebral spinal fluid, tears, urine, saliva, sputum, or combinations thereof. EP3011058A1 (178) is an example of patents focusing on total miRNA analysis. In addition, in this case, a shortlist of candidate miRNAs is provided, such as the combination of miR-365, miR-425, miR-143, miR-133a, miR-15a and miR-18a. The alteration in the level of the miRNA in the test sample (such as serum, plasma, or whole blood), relative to the level of a corresponding miRNA in a control sample, is indicative of the subject either having, or being at risk of developing, cancer, or the response of a subject to any treatment for the cancer. Further examples of miRNAs identified as cancer biomarkers are shown in Table IV.

Liquid biopsy is implemented (and is technologically tested) in several ongoing clinical trials (Tables V and VI) (183-204). For instance, NCT02639832 (183) is focused on the presence of tumor-derived CTCs or ctDNA using an investigational medical device known as the LiquidBiopsy. Using the LiquidBiopsy platform, recovered cells or DNA can also be investigated to obtain genetic information that may be useful to physicians for treating and understanding disease. The LiquidBiopsy device is able to purify the tiny numbers of tumor cells or ctDNA in blood. Even if a tumor is too small to be found by other means, such as an X-ray, it is possible that ctDNA or CTCs may be found in the blood. Genetic information can then be recovered from these cells or DNA to identify genetic alterations that are related to abnormal growth in a tumor. The proponents claim that this will potentially allow researchers to study tumor cells or tumor DNA from a blood sample instead of a biopsy sample, and may influence cancer diagnosis, treatment and drug selection in the future. In NCT02784639 (195) a method is employed which simultaneously allows the determination of three parameters: The specific quantification of tumor-derived cfDNA, the cfDNA fragmentation index and SNP or point mutation detection. The evaluation and validation of the method will be performed by determining the KRAS/BRAF mutational status prior to anti-EGFR therapy in patients with CRC. The protocol will detect the six most frequent KRAS mutations in CRC (G12D, G12V, G13D, G12S, G12C and G12A) and BRAF V600E. The goal of this multicenter prospective study is to validate, and ultimately translate in
| ClinicalTrials.gov identifier/(Refs.) | Start date | Title | Sponsors, collaborators and investigators (location) | Short description | Condition(s) |
|--------------------------------------|------------|-------|-----------------------------------------------------|-------------------|--------------|
| NCT02639832 (183)                    | First received: December 10, 2015; Last updated: August 8, 2016 | A pilot surveillance study to monitor Natural Killer Cells and Circulating Tumor Cells in women with previously treated non-metastatic triple negative breast cancer and women with previously treated non-metastatic breast cancer with a confirmed BRCA mutation | Sponsor: Cynvenio Biosystems, Inc. (Westlake Village, CA, USA) | The purpose was to test blood for the presence of tumor derived circulating tumor cells (CTCs) or circulating tumor DNA (ctDNA) using an investigational medical device. This LiquidBiopsy® device is able to purify low numbers of tumor cells or low amounts of ctDNA in the blood. Even if a tumor is too small to be found by other means such as an x-ray, it is possible that ctDNA or CTCs may be found in the blood. Genetic information can then be recovered from these cells or DNA to look for genetic changes that are related to the abnormal growth in a tumor. This will potentially allow researchers to study tumor cells or tumor DNA from a blood sample instead of a biopsy sample. This may influence cancer diagnosis, treatment and drug selection in the future. | Triple-negative breast cancer |
| NCT02626039 (184)                    | First received: October 15, 2015; Last updated: March 9, 2017 | Characterization & comparison of drugable mutations in primary and metastatic tumors, CTCs and cfDNA in MBC patients | Sponsor: Hospital General Universitario Gregorio Marañón; Principal investigator: Martín M (Hospital General Universitario Gregorio Marañón, Madrid, Spain) | In the study, it is hypothesized that breast cancer metastases and primary tumors can harbor different genomic profiles related to genomic regions of interest in a clinically relevant proportion of metastatic breast cancer patients. Furthermore, the genomic aberrations found in the metastatic breast cancer tissue can also be detected in circulating tumor cells (CTCs) and cfDNA. The study will evaluate whether CTCs and cfDNA would be convenient, non-invasive, easily accessible sources of genomic material for the analysis of mutations and other genomic aberrations. | Metastatic breast cancer |
| NCT02186236 (185)                    | First received: July 7, 2014; Last updated: September 27, 2016 | Detection of oncogenic tumor mutations in the urine and blood of lung and colorectal cancer patients | Sponsor: Memorial Sloan Kettering Cancer Center; Collaborator: Trovagene, Inc.; Principal investigator: Yu H (Memorial Sloan Kettering Cancer Center) | The purpose of the study is to determine whether gene mutations can be found in the urine or blood of patients with lung cancer and the urine of patients with colorectal cancer. The study is based on gene mutations that are only found in lung and colorectal cancer cells, but not in normal cells. In the study, a plasma-based assay is applied to determine the presence of EGFR mutation in CTC and in cfDNA | Lung cancer; colorectal cancer |
| ClinicalTrials.gov identifier/(Refs.) | Start date | Title                                                                                                       | Sponsors, collaborators and investigators (location)                                                                 | Short description                                                                                                                                                                                                                                                                                                                                                                                                   | Condition(s)                      |
|------------------------------------|------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| NCT02788084 (186)                 | First received: May 25, 2016; Last updated: June 27, 2017                                                | Development of a tissue-based & cell free DNA next-generation sequencing workflow                                      | Sponsor: Alberta Health Services, Calgary; Principal investigator: Mahe E (FRCPC; Calgary Laboratory Services, University of Calgary)                                                                                                | In the study, blood samples will be prospectively collected at scheduled follow-up and if the primary objectives of this study are met, the presence of cfDNA and the impact of variation on clinical outcomes will be assessed. A next generation sequencing (NGS) workflow will be developed for the mutation profiling of cfDNA specimens. The major issue is to calculate the proportion of cases in a test series of B-cell non-Hodgkin lymphomas (BNHL) with somatic mutations or immunoglobulin heavy chain (IGH) gene rearrangements. Participant data will be collected, and clinical outcomes will be assessed to determine the effect of mutation profiles on outcomes over a two-year follow-up. | Non-Hodgkin lymphoma             |
| NCT02883517 (187)                 | First received: August 25, 2016; Last updated: February 23, 2017                                         | Cell-free circulating DNA in primary cutaneous lymphomas                                                          | Sponsor: University Hospital, Bordeaux; Principal Investigator: Pham-Ledard A (University Hospital, Bordeaux, France)                                                                                       | This study is based on the concept that liquid biopsies allowing the detection of tumor mutation in plasma have been validated in nodal diffuse large B-cell lymphoma. The purpose of the study is to evaluate the possibility to detect cell-free circulating tumor DNA in primary cutaneous lymphomas, using a highly sensitive method (digital PCR), combined with a next generation sequencing panel of the tumor sample. | Lymphoma, large B-cell           |
| NCT02887612 (188)                 | First received: May 14, 2016; Last updated: January 17, 2018                                              | ctDNA for prediction of relapse in gastric cancer                                                               | Sponsor: Sun Yat-sen University; Principal Investigator: Xu R (Sun Yat-sen University)                                                                                                           | By monitoring the serum ctDNA mutational profile using NGS, the present clinical trial aims to elucidate the association between the serum ctDNA status and the prognosis of patients with early and intermediate-stage gastric cancer upon surgical treatment, and to explore the possibility of clinical utility of serum ctDNA as a clinical index to predict post-operative relapse. Furthermore, by comparing the molecular profiles of patients with different prognosis, it will be possible to identify molecular markers related to the prognosis of gastric cancer. | Stomach neoplasms                |
| NCT02738593 (189)                 | First received: April 6, 2016; Last updated: April 14, 2016                                               | Detection Cell Free DNA in lung cancer patients                                                               | Sponsor: Sun Yat-Sun University Cancer Center (Guangzhou, China); Principal investigator: Zhang L (Sun University Cancer Center, Guangzhou, China)                                                         | The study is based on next generation sequencing as the most sensitive and specific method to examine gene mutation and diversion. Eligible patients receiving 3rd generation EGFR-TKIs (AZD9291 and AVITINIB) were enrolled in this study. Tumor tissue sample within 6 months, and 10 ml peripheral blood samples were collected at baseline. Following treatment initiation, 10 ml peripheral blood would be collected at every imaging testing time point until disease progression. Blood samples will be drawn using EDTA tube and centrifuged within 2 h and store at -80°C in a refrigerator. NGS testing will cover target genes of non-small cell lung cancer. | Non-small cell lung cancer        |

|--------------------------------------|------------|-------|-----------------------------------------------------|-------------------|---------------|
| NCT02610218 (190) | First received: November 18, 2015; Last updated: October 31, 2017 | Liquid biopsy in monitoring the therapeutic efficacy of targeted therapy in advanced/metastatic gastric cancer | Sponsor: Peking University (Beijing, China) | The study is undertaken in patients with both histologically HER2-positive and -negative advanced/metastatic gastric cancer. Peripheral blood samples are collected from the patients for cfDNA and CTC analysis (before therapy, at the time that the patients achieve the optimal response and when they suffer progressive disease). The enumeration of CTCs, as well as the detection of HER2 expression will be achieved via the integrated subtraction enrichment (SET) and immunostaining-fluorescence in situ hybridization (iFISH) platform. Furthermore, for the genomic analysis, the enriched single CTC will be isolated for single-cell targeted sequencing. While for cfDNA analysis, extracted DNA from plasma will be directly subjected to targeted sequencing. The association of the HER2 status on CTCs and the HER2 amplification in cfDNA to the therapeutic response will be evaluated. Moreover, genetic variations associated with resistance in HER2-targeted therapy will be also studied based on the genomic data from sequencing of CTC and cfDNA | Gastric cancer |
| NCT02872779 (191) | First received: August 16, 2016; Last updated: August 22, 2017 | Correlation between circulating tumour markers early variations and clinical response in first line treatment of metastatic colorectal cancer (COCA-MACS) | Sponsor: University Hospital, Rouen (Rouen, France); Principal investigator: Gangloff A (University Hospital, Rouen, France) | The aim of the present study is to evaluate, in a prospective cohort of patients treated with systemic IV chemotherapy (5-fluorouracil +/- oxaliplatin +/- irinotecan) +/- targeted therapy as first line treatment for metastatic colorectal cancer, the correlation between early variations of circulating tumor markers including CEA, circulating tumor DNA and total cell free DNA, and the 3-month objective response as defined in the RECIST 1.1 guideline | Metastatic colorectal cancer |
| NCT02443948 (192) | First received: March 19, 2015; Last updated: February 14, 2017 | Circulating cell-free tumor DNA in the plasma of patients with gastrointestinal stromal tumors (GIST) | Sponsor: Fondazione del Piemonte per l’Oncologia | This study is based on the fact that cf-DNA may become an efficient marker of the mutational GIST status and disease itself. On this basis, this trial aims to evaluate whether tumor DNA carrying mutations (for KIT, PDGFRα, BRAF, RAS and SDH) can be detected and quantified in the plasma of patients with GISTs, either with active disease or during follow-up, and whether detection can be associated with the disease status | Gastrointestinal stromal tumor (GIST) |
Table V. Continued.

|--------------------------------------|------------|-------|-----------------------------------------------------|-------------------|--------------|
| NCT02133222 (193)                    | First received: April 30, 2014; Last updated: October 21, 2016 | Circulating cell-free DNA in metastatic melanoma patient: Mutational analyses in consecutive measurement before and after chemotherapy (AMMAM) | Sponsor: Centre Hospitalier Universitaire de Nice (Nice, France); Principal investigator: Long-Mira E (CHU de Nice, Nice, France) | In recent years, BRAF and KIT have become established therapeutic targets in patients with melanoma showing activating mutations in these oncogenes. However, it is crucial that genetic mutations present in the melanoma lesions are identified if the investigators are to design tailored therapies for individual patients. The aim of the study is to determine the mutational status in circulating DNA in patients with melanoma metastatic, with the Sequenom Mass Array, a next generation sequencing technology. Results obtained before and after treatment will be compared with the primary tumor genotype | Metastatic (Stage IV) melanoma |
| NCT02934984 (194)                    | First received: October 13, 2016; Last updated: October 17, 2016 | Circulating cell-free tumor DNA (ctDNA) in pancreatic cancer | Sponsor: Samsung Medical Center (Seoul, Republic of Korea) | In this study, ctDNA of patients with pancreatic cancer who underwent surgery will be collected, and it will be evaluated whether peripheral ctDNA can aid in the early screening of cancer recurrence. The genomic signature of ctDNA will be determined to evaluate the association between ctDNA and the clinical outcome of cancer patients | Pancreatic cancer |
| NCT02784639 (195)                    | First received: May 24, 2016; Last updated: August 3, 2016 | Comparison of KRAS/BRAF mutational status with conventional techniques and plasma samples analysis | Sponsor: Ychou M (Institut régional du Cancer de Montpellier, Montpellier, France); Principal investigator: Ychou M (Institut régional du Cancer de Montpellier, Montpellier, France) | In this study, a method is employed which simultaneously allows the determination of three parameters: The specific quantification of tumor-derived cfDNA, the cfDNA fragmentation index, and single nucleotide polymorphism (SNP) or point mutation detection. The evaluation and validation of the method will be performed by determining the KRAS/BRAF mutational status before anti-EGFR therapy in patients with colorectal cancer. The protocol will detect the six more frequent KRAS mutations in CRC (G12D, G12V, G13D, G12S, G12C and G12A) and the BRAF V600E. The goal of this multicenter prospective study is to validate, and ultimately translate into routine clinical practice, the use of plasma analysis of cfDNA for the determination of KRAS mutation status in patients with metastatic colorectal cancer | Colorectal cancer |
| NCT02036216 (196)                    | First received: January 7, 2014; Last updated: January 14, 2014 | Circulating cell-free DNA as a predictive biomarker for hepatocellular carcinoma | Sponsor: Peking Union Medical College Hospital (Beijing, China); Collaborator: Stanford University; Principal investigator: Mao Y (Peking Union Medical College Hospital (Beijing, China) | This study is based on technologies exhibiting high sensitivity and specificity detection developed at the Stanford Genome Technology Center. Some cfDNA characteristic changes, such as p161NK4A, RTL, RASSF1A, LINE-1 and GSTP1, will be examined in hepatocellular carcinoma, since studies have shown that cfDNA level is associated with intrahepatic and extra-hepatic metastasis in patients with hepatocellular carcinoma. In the study, these characteristic changes in cfDNA and primary tumor lesions will be investigated. The possible applications in early diagnosis, treatment monitoring and prognosis for hepatocellular carcinoma will be evaluated | Hepatocellular carcinoma |
Table VI. Clinical trials focusing on circulating miRNA detection in cancer diagnostics.

| ClinicalTrials.gov identifier/(Refs.) | History | Title | Sponsors, collaborators and investigators (location) | Short description | Condition(s) |
|--------------------------------------|---------|-------|---------------------------------------------------|------------------|---------------|
| NCT02791217 (197)                    | First received: May 30, 2016; Last updated: June 6, 2016 | Identification of hematological malignancies and therapy predication using microRNAs as a diagnostic tool | Sponsor: Assuta Medical Center; Collaborator: Laniado Hospital | The objective of the trial is related to the early diagnosis of very aggressive hematological malignancies as an essential approach for improving prognosis and increasing survival rates. The early diagnosis is based on the analysis of circulating miRNAs, considering that current diagnostic methods have various limitations, such as insufficient sensitivity, specificity, require time-consuming and costly approaches, and a high level of expertise, limiting applications in clinical contexts. Thus, the development of novel biomarkers (miRNAs) for the early detection and relapse of hematological malignancies is desirable. The approach is based on the readily-made detection of miRNAs in small-volume samples using specific and sensitive quantitative PCR | Lymphoma, B-Cell; follicular lymphoma; Hodgkin lymphoma; multiple myeloma |
| NCT02928627 (198)                    | First received: October 7, 2016; Last updated: October 25, 2017 | Clinical significance of hepatic and circulating microRNAs miR-221 and miR-222 in hepatocellular carcinoma | Sponsor: University of Aberdeen; Collaborator: Robert Gordon University; Principal investigator: Soggiu F (NHS Grampian) | It has been shown that miRNAs play a role in the development of hepatocellular carcinoma, but it is unknown whether these molecules can be used as markers for diagnosis and survival in hepatocellular carcinoma. In particular, the miRNAs miR-221 and miR-222 are dysregulated in tumor tissues in approximately 80% of patients with hepatocellular carcinoma. The aim of this study is to evaluate whether these two miRNAs are expressed not only in tumor tissues, but also in blood from cancer patients, and in different amounts compared to circulating levels in healthy individuals. The possible association between tumor tissue and blood levels will also be evaluated | Hepatocellular carcinoma |
| NCT02964351                          | First received: November 8, 2016; Last updated: November 16, 2016 | MicroRNA profiles identification in adenocarcinoma prostate cancer | Sponsor: Assuta Medical Center; Principal investigator: Goldberg N (Assuta Medical Center) | The main objective of the study is to determine whether an association exists between circulating miRNAs associated with prostate cancer metastases to bones and to lymph nodes, analyzed by positron emission computed (PET) imaging. miRNA profiles will be assessed by using nano-string technology validated by real-time PCR | Prostate carcinoma-sarcoma |
| NCT01541800 (200)                    | First received: February 24, 2012; Last updated: February 5, 2016 | Circulating microRNAs as disease markers in pediatric cancers | Sponsor: Ann & Robert H Lurie Children's Hospital of Chicago; Principal investigator: Lulla R (Ann & Robert H Lurie Children's Hospital of Chicago) | This study is aimed to evaluate the presence of miRNAs in the blood and cerebrospinal fluid of patients with central nervous system tumors, leukemia and lymphoma who are currently being treated with chemotherapy and are undergoing blood draws, lumbar punctures and/or reservoir taps for routine clinical care | Leukemia; lymphoma; central nervous system |
| ClinicalTrials.gov identifier/(Refs.) | History | Title | Sponsors, collaborators and investigators (location) | Short description | Condition(s) |
|------------------------------------|---------|-------|----------------------------------------------------|--------------------|--------------|
| NCT02065908 (201)                 | First received: February 15, 2014; Last updated: December 8, 2016 | Circulating microRNA as biomarker of cardiotoxicity in breast cancer | Sponsor: West Pomeranian Cancer Center; Collaborator: Pomeranian Medical University Szczecin; Principal investigator: Dąbek B (West Pomeranian Cancer Center) | In the proposed project, the investigators will assess whether changes in expression of selected circulating miRNAs in serum could comprise a sensitive and specific biomarker of cardiotoxicity in cancer patients treated with anthracycline-based chemotherapy | Breast cancer |
| NCT02812680 (202)                | First received: June 14, 2016; Last updated: January 5, 2018 | The utility of circulating tumour cells and plasma microRNA in esophageal adenocarcinoma | Sponsor: University Health Network (Toronto, ON, Canada); Principal investigator: Darling GE | The goal of this project is to assess the use of circulating miRNAs and circulating tumor cells (CTC) as biomarkers of cancer and predictive markers for neoadjuvant therapy | Esophageal cancer |
| NCT01612871 (203)                | First received: June 4, 2012; Last updated: March 5, 2018 | Circulating miRNAs as biomarkers of hormone sensitivity in breast cancer (MIRHO) | Sponsor: Institut Claudius Regaud; Principal investigator: Dalencr F (Institut Claudius Regaud) | This is a biomedical and prospective study of the interventional type, conducted in women with metastatic invasive breast cancer or locally advanced breast cancer and for which treatment with tamoxifen or anti-aromatase (first line hormone therapy for metastatic breast cancer) is indicated. The main objective of this pilot study is to evaluate the feasibility to detect in the circulating blood of patients the presence of the fifteen miRNAs described in preclinical studies as possibly involved in hormone resistance/sensitivity | Breast cancer |
| NCT01722851 (204)                | First received: October 24, 2012; Last updated: August 10, 2017 | Circulating miRNAs. ICORG 10-11, V2 | Sponsor: Cancer Trials Ireland | The main objective of the study is to identify a panel of circulating miRNA markers which could help to identify patients with breast cancer who are most likely to respond well to neoadjuvant and adjuvant chemotherapy, and indeed serve as an overall prognostic factor and stratify patients into risk categories which would further guide their management. A suitable panel of markers would show significant changes in expression level in good-responders whilst little or no change would be observed in miRNA expression in non-responders | Breast cancer |
This Horizon-2020 project is based on LIQBIOPSENS (Reliable Novel Liquid Biopsy technology for protocols and platforms, or patents) by public funding. A few selected examples (LIQBIOPSENS, is demonstrated by several international projects supported the interest in non-invasive tumor diagnosis by liquid biopsy of cancer patients. An association between tumor tissue and blood levels will also be evaluated. Table VI lists additional examples of ongoing clinical trials in breast, esophageal and prostate cancer, HCC, lymphoma and leukemias.

8. International Networks focusing on liquid biopsy

The interest in non-invasive tumor diagnosis by liquid biopsy is demonstrated by several international projects supported by public funding. A few selected examples (LIQBIOPSENS, CANCER-ID, PRECISE, BILOBA and ULTRAPLACAD) are reported in the following sections irrespectively of their success in terms of delivered products (manuscripts, validated protocols and platforms, or patents).

LIQBIOPSENS (Reliable Novel Liquid Biopsy technology for early detection of CRC). This Horizon-2020 project is based on a reliable novel liquid biopsy technology for the early detection of CRC using multidisciplinary approaches involving micro-electronics, microfluidics, nanomaterials and genomics. The overall aim of LIQBIOPSENS is the further development and validation in real settings of a novel diagnostic platform for the early and rapid detection of ctDNA and their KRAS and BRAF mutations associated with CRC through blood samples. This sensitive (in the zM range) assay includes 27 KRAS and BRAF mutations, to be simultaneously analyzed. Other main features of LIQBIOPSENS are reliability, low-cost and short analysis time. Furthermore, a user-friendly and flexible interface is provided. Among the participants are DestiNA Genomics Ltd. (UK); the Foundation for Research and Technology Hellas, Greece; the Servicio Andaluz del Salud, Spain; BEABLE SL, Spain; Université Catholique de Louvain, Belgium and Sistemas Genomicos SL, Spain (http://liqbiopsens.com).

CANCER-ID (cancer treatment and monitoring through the identification of CTCs and tumor-related nucleic acids in blood). This is a newly formed European consortium funded by the Innovative Medicines Initiative (IMI) with currently 33 partners from 13 countries aiming at the establishment of standard protocols for, and the clinical validation of, blood-based biomarkers. It brings together experts from academic and clinical research, innovative small-to-medium sized enterprises (SMEs), diagnostics companies and the pharmaceutical industry, thus providing a unique setting for establishing clinical utility of liquid biopsy. The academic leads of the CANCER-ID consortium are Professor Klaus Pantel, Head of the Department of Tumor Biology at the University Medical Center Hamburg-Eppendorf, Hamburg, Germany, and Professor Leon Terstappen, Head of the Department of Medical Cell Biophysics at the University of Twente, Enschede, The Netherlands. The lead companies of the CANCER-ID consortium are Bayer HealthCare and Silicon Biosystems, A Menarini Group Company (http://www.cancer-id.eu).

PRECISE (Personalized Engine for Cancer Integrative Study and Evaluation). This project is an Horizon-2020 pilot project that combines hypothesis-driven strategies with data-driven analysis in a novel mathematical and computational methodology for the integration of genomic, epigenetic, transcriptomic, proteomic and clinical data with the goal of risk-stratifying patients and suggesting personalized therapeutic interventions. As far as motivation is concerned, the PRECISE project is based on the concept that, despite their great promise, high-throughput technologies in cancer research have often failed to translate to major therapeutic advances in clinical practice. One challenge has been tumor heterogeneity, where multiple competing subclones co-exist within a single tumor. Genomic heterogeneity renders it difficult to identify all driving molecular alterations, and thus results in therapies that only target subsets of aggressive tumor cells. Another challenge lies in the integration of multiple types of molecular data into mathematical disease models that can make actionable clinical statements. PRECISE aims to develop predictive computational technology that can exploit molecular and clinical data to improve our understanding of disease mechanisms and to inform clinicians about optimized strategies for therapeutic intervention. The Precise project will focus on two urgent clinical needs in prostate cancer: i) Distinguishing the many indolent tumors from the minority of lethal ones; and ii) providing rationally selected treatment options for patients with advanced disease (http://www. precise-project.eu).

BILOBA (Bloch electromagnetic surface wave biosensors for early cancer diagnosis). BILOBA is a collaborative project funded by the European Commission through its Seventh Framework Program. The major goal of the project is to explore, design and set-up systems optimized for analytical sensing, associated with the development of a corresponding analytical instrument. For this purpose, the immobilization protocols and biochemical assays have been established to ensure an optimized binding site density at the surface of SPR sensors and to enable the detection of the target biomarkers. Furthermore, a fluidic system has been developed for handling the aqueous analyte solutions ensuring a high signal-to-noise ratio and robust results even in the case of ultra-low concentrations. The BILOBA multifunctional point-of-care platform is expected to be capable of performing real-time cancer biomarker detection in a tandem configuration. The BILOBA project consists of 9 participants from different European countries, including the Department of Basic and Applied Sciences for Engineering (Università degli Studi di Roma ‘La Sapienza’, Rome, Italy); the Department of Applied Sciences and Technology (Politecnico di Torino, Torino, Italy); Fraunhofer Gesellschaft, Munich, Germany; the Department of Materials (Imperial College London, London, UK), the Department of Oncology (Università degli Studi di Torino, Torino, Italy); Labor Srl, Rome, Italy; Biotray SAS, Lyon, France; Horiba Jobin Yvon SAS, Paris, France; KDS...
arrays of metallic nanoparticles. Those structures hold the potential for plasmon modes supported by continuous metallic films and novel plasmonic structures will be delivered based on surface diagnostic model systems. KRAS mutations limit the signal-to-noise ratios. With respect to the proposed plasmons will be developed, in order to increase sensitivity and platform based on the diffraction coupling of light into surface. tive index changes. In the ULTRAPLACAD project, an SPRI target analytes through biomolecular binding-induced refractive index changes. In the ULTRAPLACAD project, novel plasmonic structures will be delivered based on surface plasmon modes supported by continuous metallic films and arrays of metallic nanoparticles. Those structures hold the potential for a breakthrough enhancement of sensitivity. Moreover, this method will be implemented in an innovative compact biosensor device based on an integration of key optical elements for the excitation and collecting of fluorescence light directly on the sensor chip. The SPRI approach is based on the detection of target analytes through biomolecular binding-induced refractive index changes. In the ULTRAPLACAD project, an SPRI platform based on the diffraction coupling of light into surface plasmons will be developed, in order to increase sensitivity and limit the signal-to-noise ratios. With respect to the proposed diagnostic model systems, KRAS and BRAF mutations are considered, since they are routinely assessed in genomic DNAs from surgically removed lesions of colorectal carcinoma, breast cancer, melanoma and other tumors. As far as miRNA target sequences are concerned, miR-221, miR-222, miR-141, miR-155, miR-21, let-7a and miR-16 are considered, since these miRNA molecules are available in circulating exosomes, and could mark tumor aggressiveness. ULTRAPLACAD is the only project in which ctDNAs, miRNAs and proteins, e.g., the three major analyte classes, are combined in a single detection platform (www.ultraplacad.eu).

9. Conclusions

The liquid biopsy of cancer is mainly based on the analysis of CTCs and/or cell-free nucleic acids in the peripheral blood of cancer patients, as well as in other body fluids suitable for diagnostic assessment. Among these, cerebrospinal fluid for tumors of the central nervous system, saliva for tumors affecting the head and neck, pleural effusion in the case of respiratory tract cancers and urine for urinary tract cancers. At present, liquid biopsy should be considered one of the most advanced non-invasive diagnostic systems suitable for performing key clinically relevant actions possibly leading to precision medicine. Historically, the applications of liquid biopsy for the characterization of cancer patients have been focused on CTCs. More recently, this analysis has been extended to ctDNA and miRNAs, demonstrated to be associated with cancer, with potential applications in early diagnosis, staging, prognosis, prediction of therapeutic responses, therapeutic outcome, and follow-up during therapeutic intervention. Liquid biopsy measures alterations in gene structure, regulation and expression that are the hallmarks of cancer. These analytes include nucleotide variants, promoter methylation, copy number variations of specific genes, chromosomal rearrangements, mutations affecting transcription, splicing and RNA maturation, translational efficiency and differences in miRNA signatures. The analysis of all these parameters can be approached by a variety of technological platforms. Moreover, the great interest of liquid biopsy is that this approach avoids certain key issues associated with invasive surgical biopsy. These include, but are not limited to: i) A static representation of the tumor pathology strictly limited to the tumor tissue sampling; ii) ethical and practical issues preventing repeated tissue biopsy; iii) tumor heterogeneity, particularly during progression and metastatic dissemination (making multiple sampling necessary); iv) easier patient monitoring by non-invasive analytical procedures (i.e., liquid biopsy). Therefore, despite the fact that the liquid biopsy approach suffers from important drawbacks (fragmentation of ctDNA, instability of RNA, low yield of isolated samples to be analyzed and variable presence of normal DNA and RNA) this approach is generally deemed of great interest for future applications, patent development and clinical trials. These will ultimately verify the potential of liquid biopsy in cancer. It is not expected that liquid biopsy will replace surgical biopsy; however, it will probably complement within a few years the information routinely obtained by excisional, incisional, surgical and needle biopsies, becoming a tool of choice for the dynamic monitoring of patients during clinical treatment and during the long-term surveillance of their health status.

Funding

This study was supported by the European Union (EU) Horizon 2020 Research and Innovation Programme (GA #633937, project ULTRAsensitive PLAsmonic devices for early CANcer Diagnosis (ULTRAPLACAD), and by Associazione Italiana per la Ricerca sul Cancro (AIRC) (IG #13575 to RG, IG# 14204 and IG #19052 to PG), MA is the recipient of an AIRC, Nuvenia Fellowship id. 19503.

Availability of data and materials

Not applicable.

Authors' contributions

All authors were involved in the conception of the study, and revised and approved the final manuscript. All authors take the responsibility for publishing this review paper. AF, PG, GS and RG performed the literature search, wrote the manuscript, and critically analyzed the existing knowledge; AF and RG designed the figures; AF, MA, JG and RG have ideated and drew the tables; AF, JG and RG were involved in the acquisition of data and in the analysis of patents and clinical trials; JG and MA significantly contributed to editing the manuscript; PG, DAS, GS and RG significantly contributed to the analyses of international networks focusing on liquid biopsy. AF, PG,
DAS, GS and RG were significantly involved in the drafting of the manuscript.
