TRIVARIATE MONOMIAL COMPLETE INTERSECTIONS AND PLANE PARTITIONS

CHARLES CHEN, ALAN GUO, XIN JIN, AND GAKU LIU

Abstract. We consider the homogeneous components $U_r$ of the map on $R = \mathbb{k}[x, y, z]/(x^A, y^B, z^C)$ that multiplies by $x + y + z$. We prove a relationship between the Smith normal forms of submatrices of an arbitrary Toeplitz matrix using Schur polynomials, and use this to give a relationship between Smith normal form entries of $U_r$. We also give a bijective proof of an identity proven by J. Li and F. Zanello equating the determinant of the middle homogeneous component $U_r$ when $(A, B, C) = (a + b, a + c, b + c)$ to the number of plane partitions in an $a \times b \times c$ box. Finally, we prove that, for certain vector subspaces of $R$, similar identities hold relating determinants to symmetry classes of plane partitions, in particular classes 3, 6, and 8.

1. Introduction

For a commutative ring $\mathbb{k}$ and positive integers $A, B, C$, consider the trivariate monomial complete intersection $R = \mathbb{k}[x, y, z]/(x^A, y^B, z^C)$. This carries a standard grading in which $x, y, z$ each have degree one, and decomposes as a direct sum $R = \bigoplus_{r=0}^{e-3} R_r$, where $e := A + B + C - 3$, and each homogeneous component $R_r \cong \mathbb{k}^{h(r)}$, where $h(r)$ denotes the size of the set $B_r$ consisting of all monomials of total degree $r$ in $x, y, z$ which are nonzero in $R$. It is easily seen that $(h(0), h(1), \ldots, h(e))$ is a symmetric unimodal sequence. Furthermore, it is known that the maps

$$U_r : R_r \xrightarrow{(x+y+z)} R_{r+1}$$

have $U_{r-1}^t = U_r$, and that $U_r$ is injective for $0 \leq r \leq \lfloor \frac{e-1}{2} \rfloor$ when working with $\mathbb{k} = \mathbb{Z}$ or $\mathbb{Q}$ (or, in fact, with any field of characteristic zero).

The maps $U_r$ arise in a more general setting in algebraic geometry and commutative algebra when studying the Weak Lefschetz Property of general hyperplane sections. Algebraically, one studies the multiplication by a general linear form $\ell$ on a graded algebra $S/I$, where $I$ is a homogeneous ideal in a polynomial ring $S$. If $I$ is a monomial ideal, it has been observed in [11, Prop 2.2] that choosing $\ell$ as the sum of the variables is enough to determine if the algebra has the Weak Lefschetz Property. The paper focuses on one non-trivial case when one considers the Weak Lefschetz Property and one that has recently been studied ([10], [2]).

Our first main result attempts to address how the maps $U_r$ behave, by considering the Smith normal form of $U_r$ when working over $\mathbb{k} = \mathbb{Z}$. We say that a matrix $U$ in $\mathbb{Z}^{m \times n}$, $m \geq n$, has $\text{SNF}(U) = (a_1, a_2, \ldots, a_n)$ if there exist matrices $P, Q \in \text{GL}_m(\mathbb{Z}), \text{GL}_n(\mathbb{Z})$ such that $PUQ$ takes the

2010 Mathematics Subject Classification. Primary: 05E40; Secondary: 05E05, 05E18, 13E10, 15A15.
diagonal form
\[
\begin{pmatrix}
  a_1 & 0 & \cdots & 0 & 0 \\
  0 & a_2 & \cdots & 0 & 0 \\
  \vdots & \vdots & \ddots & \vdots & \vdots \\
  0 & 0 & \cdots & a_{n-1} & 0 \\
  0 & 0 & \cdots & 0 & a_n
\end{pmatrix}
\]
and \( a_i \) divides \( a_{i+1} \).

**Theorem 1.1.** Assume \( A \geq B \geq C \geq 1 \).

(i) For \( 0 \leq r \leq A - 2 \),

\[
\text{SNF}(U_r) = (1,1,\ldots,1)
\]

In particular, these maps \( U_r \) are injective when \( k \) is any field.

(ii) For \( A - 1 \leq r \leq \lfloor \frac{A-1}{2} \rfloor \), the non-unit entries in \( \text{SNF}(U_r) \) are the same as the non-unit entries of \( \text{SNF}(M_r(A,B,C)) \) where

\[
M_r(A,B,C) := \left( \begin{array}{c}
A \\
B + i - j + 2 \\
\end{array} \right)_{i=1}^{A},j=1,r-A+2.
\]

In particular, there are at most \( r - A + 2 \) such non-unit entries, so that for any field \( k \), the map \( U_r \) has nullity at most \( r - A + 2 \).

(iii) Let \( m := \lfloor \frac{A-1}{2} \rfloor \), so that \( U_m : R_m \rightarrow R_{m+1} \) is a map closest to the “middle” of \( R \). If \( \text{SNF}(U_m) = (a_1,a_2,\ldots,a_{h(m)}) \), then for \( 0 \leq s \leq m \) one has

\[
\text{SNF}(U_{m-s}) = (\underbrace{1,1,\ldots,1}_{s-h(m)-s},a_1,a_2,\ldots,a_{h(m)}).
\]

On the way to proving this theorem, we prove two lemmas. The first lemma provides a relationship between the Smith normal forms of submatrices of an arbitrary Toeplitz matrix using Schur polynomials (Lemma 2.6), and the second lemma proves an “inverse” Littlewood-Richardson rule (Lemma 3.6). Both of these lemmas might be of independent interest.

Our other main results relate to the middle map \( U_m \) when \( A + B + C \) is even (and without loss of generality, \( A \leq B + C \)) so that \( r = m \) does not fall in the trivial case (i) of Theorem 1.1 above).

In this case, one can check that \( h(m) = h(m+1) \), so that \( U_m \) is square. Li and Zanello proved the striking result that \( \det(U_m) \), up to sign, counts the number of plane partitions that fit in an \( a \times b \times c \) box where \( a := \frac{A+B-C}{2}, b := \frac{A-B+C}{2}, c := \frac{C+B-A}{2} \) so that \( A = a + b, B = a + c, C = b + c \). Their proof proceeded by evaluating

\[
\det(U_m) = \det(M_m(A,B,C))
\]
directly, and comparing the answer to known formulae for such plane partitions. We respond to their call for a more direct, combinatorial explanation (see [10]) with the following:

**Theorem 1.2.** Expressed in the monomial \( \mathbb{Z} \)-basis for \( R = \mathbb{Z}[x, y, z]/(x^{a+b}, y^{a+c}, z^{b+c}) \) the map \( U_m : R_m \rightarrow R_{m+1} \) has its determinant \( \det(U_m) \) equal, up to sign, to its permanent \( \text{perm}(U_m) \), and each nonzero term in its permanent corresponds naturally to a plane partition in an \( a \times b \times c \) box.
The same ideas then allow us to express the counts for other symmetry classes of plane partitions, namely those which are cyclically symmetric (class 3) or transpose complementary (class 6) or cyclically symmetric and transpose complementary (class 8), in terms of the determinant of $U_m$ when restricted to certain natural $\mathbb{Z}$-submodules of $R$.

**Theorem 1.3.** Assuming $a = b = c$, let $C_3 = \mathbb{Z}/3\mathbb{Z} = \{1, \rho, \rho^2\}$ act on $R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{2a}, z^{2a})$ by cycling the variables $x \stackrel{\rho}{\rightarrow} y \stackrel{\rho}{\rightarrow} z \stackrel{\rho}{\rightarrow} x$. Then the map $U_m|_{RC_3}$ restricted to the $m$-th homogeneous component of the $C_3$-invariant subring $R^{C_3}$ has $\det(U_m|_{RC_3})$ equal, up to sign, to the number of cyclically symmetric plane partitions in an $a \times a \times a$ box.

**Theorem 1.4.** Assuming $a = b$ and the product $abc$ is even, let $C_2 = \mathbb{Z}/2\mathbb{Z} = \{1, \tau\}$ act on $R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{2a}, z^{2a})$ by swapping $y \leftrightarrow z$. Then the map $U_m|_{RC_2}$ restricted to the $m$-th homogeneous component of the anti-invariant submodule $R^{C_2^-} := \{f \in R : \tau(f) = -f\}$ has $\det(U_m|_{RC_2^-})$ equal, up to sign, to the number of transpose complementary plane partitions in an $a \times a \times c$ box.

**Theorem 1.5.** Assuming $a = b = c$ are all even, let $C_2, C_3$ act on $R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{2a}, z^{2a})$ as before. Then the map $U_m|_{RC_3 \cap RC_2^-}$ restricted to the $m$-th homogeneous component of the intersection $R^{C_3} \cap R^{C_2^-}$ has $\det(U_m|_{RC_3 \cap RC_2^-})$ equal, up to sign, to the number of cyclically symmetric transpose complementary plane partitions in an $a \times a \times a$ box.

2. Proof of Theorem 1.1

**Proof of Theorem 1.1** part (i): Recall the statement of Theorem 1.1 part (i):

**Theorem.** For $0 \leq r < A - 1$, $\text{SNF}(U_r) = \{1, \ldots, 1\}$. In other words, the cokernel of $U_r$ is free of rank $h(r + 1) - h(r)$.

**Proof.** Let $B_i$ denote the monomial basis of $R_i$. We represent $U_r$ by a matrix whose columns and rows are indexed by elements of $B_i$ and $B_i + 1$, respectively. We will prove our claim by showing that, for some ordering of the rows and columns of the matrix of $U_r$, there exists a lower unitriangular maximal submatrix. To do this, it suffices to show that there exists an ordering of the columns such that, for each column $j$, there exists a row $i$ such that the $(i, j)$ entry is 1 and the entries to the right are 0. We arrange the columns lexicographically, so that monomials with higher $x$ power are on the left, and if $x$ powers are equal, then we use the power of $y$ to break ties, and then the power of $z$ to break remaining ties. For example, for $A = B = C = 4$ and $r = 4$, the monomials would be ordered

$$x^3y \ x^3z \ x^2y^2 \ x^2yz \ x^2z^2 \ x^3y \ xy^2 \ x^3z \ y^2z \ x^2y^2 \ y^3z \ y^2z^2 \ y^3z^2.$$

For any given monomial $x^iy^jz^k$ indexing a column, the monomial $x^{i+1}y^jz^k$ is nonzero in the quotient ring $k[x, y, z]/(x^A, y^B, z^C)$ since $i + 1 \leq i + j + k + 1 < A$. Therefore $x^{i+1}y^jz^k$ indexes a row. The entry of this row in column $x^iy^jz^k$ is 1, and any other column with a 1 in this row must be indexed by either $x^{i+1}y^{j-1}z^k$ or $x^{i+1}y^jz^{k-1}$, both of which lie to the left of $x^iy^jz^k$.

**Remark 2.1.** From the previous proposition, it follows that all the maps $U_r$ of $k[x, y]/(x^A, y^B)$ (setting $C = 1$) and $k[x]/(x^A)$ (setting $B = C = 1$) have free cokernel. Note that this immediately proves the Weak Lefschetz Property for (essentially all) codimension 2 monomial Artinian complete intersections, regardless of characteristic. (To be precise, we require the base field to be infinite. We can define the Weak Lefschetz Property over finite fields, but it becomes too pathological to be of interest.) More generally, it turns out that the WLP holds for any codimension 2 standard graded Artinian algebra [12].

TRIVARIATE MONOMIAL COMPLETE INTERSECTIONS AND PLANE PARTITIONS 3
In the other extreme (with an arbitrary number of variables and bounded powers), Wilson completely determined the cokernel of the maps $U_r$ for $k[x_1, \ldots, x_n]/(x_1^2, \ldots, x_n^2)$ \cite{Wilson}. Moreover, Hara and Watanabe provided an elementary proof of Wilson’s result and used it to show the Strong Lefschetz Property for $k[x_1, \ldots, x_n]/(x_1^2, \ldots, x_n^2)$ over certain fields \cite{Hara}. We warn the reader that Hara and Watanabe’s result is not characteristic free. For instance, when $n = 2$, the SLP result for $k[x_1, x_2]/(x_1^2, x_2^2)$ fails in characteristic 2, as multiplication by $(x + y)^2$ is not injective.

Things get interesting when $A - 1 \leq r \leq \frac{x}{2}$. The up maps are no longer necessarily injective over arbitrary fields. However, we can still prove a least upper bound on the number of non-unit elements in $\text{SNF}(U_r)$. In fact, we have the following

**Proof of Theorem \[1.1\] part (ii).** Recall the statement of Theorem \[1.1\] part (ii):

**Theorem.** For $A - 1 \leq r \leq \frac{x}{2}$, the non-unit entries in $\text{SNF}(U_r)$ are the same as the non-unit entries of $\text{SNF}(M_r(A, B, C))$ where

$$M_r(A, B, C) := \left( \begin{array}{c} A \\ r - B + i - j + 2 \end{array} \right)_{i=1, \ldots, B+C-r+2}.$$ 

In particular, there are at most $r - A + 2$ such non-unit entries, so that for any field $k$, the map $U_r$ has nullity at most $r - A + 2$.

**Proof.** We construct a matrix $U_r(y, z)$ as follows. First, represent $U_r$ as a matrix in the monomial basis with a lexicographic ordering on its rows and columns, as in the previous proof. For each 1 in $U_r$, if the row index divided by the column index equals $y$, replace the 1 with $y$, and similarly for $z$. Then move all the columns indexed by monomials with $x^{A-1}$ to the right, maintaining the ordering amongst these columns. There are $r - A + 2$ such columns: for $x^{A-1}y^jz^k$, with $j + k = r - A + 1$, note that since $r \leq \frac{A + B + C - 3}{2}$ implies $r - A + 1 \leq \frac{B + C - A - 1}{2} \leq \frac{C - 1}{2} < B - 1, C - 1$, $j$ can take on every value from 0 to $r - A + 1$. Now we claim that there are $B + C - r - 2$ monomials of rank $r + 1$ with no powers of $x$. First, note that $r \leq \frac{A + B + C - 3}{2}$ implies $B + C - r - 2 \geq r - (A - 1) \geq 0$. Now, the monomials of rank $r + 1$ with no powers of $x$ are precisely $y^{C - 1}z^{r + 2 - C}, y^{C - 2}z^{r + 3 - C}, \ldots, y^{r - 2}z^{B - 1}$. We now have a matrix of the form

$$U_r(x, y) = \begin{pmatrix} 1 & 0 & \cdots & * \\ \vdots & \ddots & \ddots & \vdots \\ * & 1 & & * \\ * & & 0 & \end{pmatrix}$$

where the lower right block of zeroes has $B + C - r - 2$ rows and $r - A + 2$ columns. Now we perform the following algorithm: initialize $M := U_r(y, z)$. While

$$M = \begin{pmatrix} 1 & X \\ Y & M' \end{pmatrix}$$

and $M$ has more than $r - A + 2$ rows, set $M := M' - XY$. Each step of the algorithm is using the 1 in the first row and first column as a pivot and performing $Z$-invertible row and column operations on $M$ to eliminate the other entries in the same row and same column. Then we focus on the remaining submatrix $M'$ and repeat.
Lemma 2.2. At each step of the algorithm, the following holds: fix a monomial $\alpha$ of total degree $r - A + 1$ with no powers of $x$, fix a nonnegative integer $\gamma$ and a monomial $\beta$ of total degree $r + 1 - \gamma$ with no powers of $x$, and let $\mu$ be the entry of $M$ whose column is indexed by $x^{A-1}\alpha$ and whose row is indexed by $x^\gamma \beta$, and suppose $\beta / \alpha = y^j z^k$. If no entry to the left of $\mu$ indexed by a monomial whose power of $x$ is less than $A - 1$ is a $y$ or $z$, then $\mu = (-1)^{A-\gamma-1} (j + k) y^j z^k$.

Proof. This statement is true at the beginning of the algorithm. We now proceed inductively. Suppose $\mu$ is as in the statement of the Lemma. Suppose $yz$ divides $\beta$. For some previous step of the algorithm, there existed an entry $\mu_y$ whose column was indexed by $x^{A-1}\alpha$ and whose row was indexed by $x^{\gamma+1} \beta / y$, and no entry to the left of $\mu_y$ indexed by something with $x$ power less than $A - 1$ was a $y$ or $z$. We have the following setup:

$$
\begin{pmatrix}
x^\gamma \beta / y & \cdots & x^{A-1}\alpha & \cdots \\
x^{\gamma+1} \beta / y & 1 & \cdots & \mu_y & \cdots \\
\vdots & \vdots & \ddots & \vdots \\
x^\gamma \beta & y & \cdots \\
\end{pmatrix}
$$

Similarly, for some previous step of the algorithm, there existed an entry $\mu_z$ whose column was indexed by $x^{A-1}\alpha$ and whose row was indexed by $x^{\gamma+1} \beta / z$, and no entry to the left of $\mu_z$ indexed by something with $x$ power less than $A - 1$ was a $y$ or $z$. We have an analogous setup:

$$
\begin{pmatrix}
x^\gamma \beta / z & \cdots & x^{A-1}\alpha & \cdots \\
x^{\gamma+1} \beta / z & 1 & \cdots & \mu_z & \cdots \\
\vdots & \vdots & \ddots & \vdots \\
x^\gamma \beta & z & \cdots \\
\end{pmatrix}
$$

By the algorithm, after both of these steps, we end up with $\mu = -y\mu_y - z\mu_z$. But by induction,

$$
-y\mu_y - z\mu_z = -y(-1)^{A-\gamma-2} \binom{j + k - 1}{j - 1} y^{j-1} z^k - (-1)^{A-\gamma-2} \binom{j + k - 1}{j} y^j z^{k-1}
$$

$$
= (-1)^{A-\gamma-1} \left( \binom{j + k - 1}{j - 1} + \binom{j + k - 1}{j} \right) y^j z^k
$$

$$
= (-1)^{A-\gamma-1} \binom{j + k}{j} y^j z^k.
$$

In the case where $yz$ does not divide $\beta$, at least one of these previous steps did not exist, but our argument still applies and the result still follows. \qed

In particular, the Lemma implies that, at the end of the algorithm, the matrix $M$ has $(B+C-r-2)$ rows and $(r-A+2)$ columns and takes the form

$$
(-1)^{A-1} \binom{A}{r - B + i - j + 2} y^{A+B-r-i+j-2} z^{r-B+i-j+2} i_{i,j}.
$$

Recall that at each step of the algorithm, we are simply performing a sequence of $\mathbb{Z}$-invertible row and column operations. Therefore $U_r(y,z)$ and $(-1)^{A-1} M$ have the same non-unit Smith normal form entries. Substituting $y = z = 1$ gives the result. \qed

Remark 2.3. Note that after substituting $A = a + b$, $B = a + c$, $C = b + c$, we return to the context of the plane partitions. In this case, our matrix $M_r(A,B,C)$ becomes an $(r-a-b+2) \times (a+b+2c-r-2)$
matrix with entries
\begin{equation}
M_r(a + b, a + c, b + c) = \begin{pmatrix} a + b \\ r - a - c + i - j + 2 \end{pmatrix}_{i,j}.
\end{equation}

Focusing on the middle rank \( r = a + b + c - 2 \) yields a \( c \times c \) matrix
\[
M_r(a + b, a + c, b + c) = \begin{pmatrix} a + b \\ b + i - j \end{pmatrix}_{i,j}.
\]

The matrix \( M_{a+b+c-2}(a+b, a+c, b+c) \) is called a Carlitz matrix \([9]\), and occurs in \([10] \text{ Lemma 2.2}\) and \([3] \text{ Theorem 4.3}\). The Smith normal form of these matrices is not known, but Kuperberg conjectures that there is a potential combinatorial connection between plane partitions and Smith forms of Carlitz matrices \([9]\). Even for small numbers, however, it is subtle to understand (and even to compute!) the Smith forms. We give some small examples:

When \( c = 1 \), the only Smith entry is \((a+b)\). When \( c = 2 \) and \( a = b \), the explicit row and column operations to turn \( M_{a+b+c-2}(a+b, a+c, b+c) \) into Smith normal form are

\[
\begin{pmatrix} 1 & -1 \\ -1 - 3a & 2 + 3a \end{pmatrix} M_{a+b+c-2}(a+b, a+c, b+c) = \begin{pmatrix} (a + b)^2 & 2 \\ a + 1 & 1 \end{pmatrix} \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} (\frac{a}{a+1})^2 & 0 \\ a+1 & (\frac{a}{a+1}) \end{pmatrix}.
\]

Even though the first entry is the \( a \)-th Catalan number, a combinatorial explanation of the Smith entries eludes the authors.

Directly calculating the Smith entries by computing GCDs of various binomial coefficients seems intractable and does not seem to generalize for bigger \( c \). In particular, the direct method seems hard to understand even when \( c = 2 \) and \( a, b \) are arbitrary. In that case, the Smith entries are

\[ s_1 = \gcd \left( \frac{(a+b)^2}{b-1}, \frac{(a+b)^2}{b}, \frac{(a+b)^2}{b+1} \right) \]

\[ s_2 = \frac{(a+b)^2}{b} \frac{(a+b)^2}{b+1} \frac{a}{a+1}. \]

**Remark 2.4.** If \( R = \mathbb{K}[x_1, \ldots, x_n] / (x_1^{A_1}, \ldots, x_n^{A_n}) \), then we can easily generalize the proof above to show that the non-unit Smith entries of the map \( U_r \) (which is now defined by multiplication by \( x_1 + \cdots + x_n \)) for \( A_1 - 1 \leq r \leq \frac{A_1 \cdots A_n}{2} \) are the same as those of the matrix with the following entries, assuming \( A_1 \geq A_2 \geq \cdots \geq A_n \); if the column is indexed by \( x_1^{A_1-1}a \) and the row is indexed by \( b \) where \( x \) divides neither \( a \) nor \( b \), and \( \beta/a = x_1^2 \cdots x_n^2 \), then the entry is the multinomial coefficient

\[
\binom{A_1}{i_2, i_3, \ldots, i_n} = \frac{A_1!}{i_2!i_3! \cdots i_n!}.
\]

Computer evidence suggests that the non-unit Smith entries of these matrices behave nicely for \( n = 4 \) (as in \( \text{SNF}(U_r) \) is a submultiset of \( \text{SNF}(U_{r+1}) \)), but the analogous result is unfortunately not true for \( n = 5 \): taking \( A_1 = A_2 = A_3 = A_4 = A_5 = 4 \), the Smith entry 70 occurs in \( \text{SNF}(U_6) \) but not in \( \text{SNF}(U_7) \).

Letting \( s(r) \) denote the number of non-unit Smith normal form entries of \( U_r \) and \( m = a + b + c - 2 \), Theorem \([1, \text{ part } ii]\) implies that \( s(m - i) \leq c - i \) for all \( i \leq c \). In fact, something stronger holds, which is Theorem \([1, \text{ part } iii]\).

**Proof of Theorem 1.1 part (iii).** Recall the statement of Theorem 1.1 part (iii):

**Theorem.** Let \( m \colonequals \left\lceil \frac{c-1}{2} \right\rceil \), so that \( U_m : R_m \to R_{m+1} \) is a map closest to the “middle” of \( R \). If \( \text{SNF}(U_m) = (a_1, a_2, \ldots, a_{h(m)}) \), then for \( 0 \leq s \leq m \) one has

\[
\text{SNF}(U_{m-s}) = \left( \prod_{s-h(m)+h(m-s)}^1 \right), a_1, a_2, \ldots, a_{h(m-s)}).
\]
Immediately from part (iii) of Theorem 1.1, we re-derive a special case of [11, Prop 2.1(b)]:

**Corollary 2.5.** The maps $U_r$ for $r \leq m$ are injective if and only if $U_m$ is injective.

Recall the matrices $M_r(A, B, C)$ given by [11]. The first one, $M_{A-1}(A, B, C)$, is a matrix with 1 column and $-A + B + C - 1$ rows, and in general, the $i$-th matrix has $i$ columns and $-A + B + C - i$ rows. We observe that in fact these are all submatrices of the $(-A + B + C - 1) \times (-A + B + C - 1)$ lower triangular Toeplitz matrix with entries

$$
\begin{pmatrix}
A & 0 & \cdots & 0 & 0 \\
A & A & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
A & A & \cdots & A & A \\
A & A & \cdots & A & A \\
\end{pmatrix}_{i,j}
$$

for $i \geq j$, and 0 otherwise, which, written out, looks like

For $1 \leq i \leq \frac{-A + B + C}{2}$, the matrix $M_{A-2+i}(A, B, C)$ is simply the submatrix of the Toeplitz matrix created by choosing the first $i$ columns and the last $-A + B + C - i$ rows. Surprisingly, there is nothing special about the entries of the large Toeplitz matrix! We have the following more general result, which immediately implies part (iii) of Theorem 1.1.

**Lemma 2.6.** Let $A$ be an arbitrary $n \times n$ Toeplitz matrix,

$$
A = \begin{pmatrix}
h_n & h_{n-1} & h_{n-2} & \cdots & h_1 \\
h_{n-1} & h_n & h_{n-1} & \cdots & h_2 \\
h_{n-2} & h_{n-1} & h_n & \cdots & h_3 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
h_1 & h_2 & h_3 & \cdots & h_n \\
\end{pmatrix}
$$

with entries in a principal ideal domain, and for $1 \leq c \leq n$, let $A_c$ denote the $(n - c + 1) \times c$ submatrix of $A$ formed by columns 1, $\ldots$, $c$ and rows $c, \ldots n$. Then, for $1 \leq k \leq \frac{n}{2}$, the $k$-th Smith normal form entry of $A_c$ is the same for all $k \leq c \leq \frac{n}{2}$.

Our proof of Lemma 2.6 requires a bit of algebraic machinery, so we defer it to its own section.

3. **Proof of Lemma 2.6**

Suppose $M$ is a matrix over a PID with Smith normal form entries $a_1 \leq a_2 \leq \cdots \leq a_r$. Then it is known (see [13]) that

$$
a_k = \frac{\gcd(k \times k \text{ minors of } M)}{\gcd((k-1) \times (k-1) \text{ minors of } M)}.
$$

Therefore, to prove Lemma 2.6, it suffices to show that, for $1 \leq k \leq c \leq \frac{n}{2}$, the ideal generated by the $k \times k$ minors of $A_c$ is equal to the ideal generated by the $k \times k$ minors of $A_k$. 

Example 3.1. Suppose $n = 7$. The matrix $A$ is
\[
A = \begin{pmatrix} h_7 & h_7 \\ h_6 & h_7 \\ h_5 & h_6 & h_7 \\ h_4 & h_5 & h_6 & h_7 \\ h_3 & h_4 & h_5 & h_6 & h_7 \\ h_2 & h_3 & h_4 & h_5 & h_6 & h_7 \\ h_1 & h_2 & h_3 & h_4 & h_5 & h_6 & h_7 \end{pmatrix}
\]
and
\[
A_1 = \begin{pmatrix} h_7 \\ h_6 \\ h_5 \\ h_4 \\ h_3 \\ h_2 \\ h_1 \end{pmatrix}, \quad A_2 = \begin{pmatrix} h_6 & h_7 \\ h_5 & h_6 \\ h_4 & h_5 \\ h_3 & h_4 \\ h_2 & h_3 \\ h_1 & h_2 \end{pmatrix}, \quad A_3 = \begin{pmatrix} h_5 & h_6 & h_7 \\ h_4 & h_5 & h_6 \\ h_3 & h_4 & h_5 \\ h_2 & h_3 & h_4 \\ h_1 & h_2 & h_3 \end{pmatrix}, \quad A_4 = \begin{pmatrix} h_4 & h_5 & h_6 & h_7 \\ h_3 & h_4 & h_5 & h_6 \\ h_2 & h_3 & h_4 & h_5 \\ h_1 & h_2 & h_3 & h_4 \end{pmatrix}.
\]

The case $k = 1$ is trivial because the $1 \times 1$ minors of the matrices are just the entries themselves. The $k = 2$ case is slightly more complicated. For example, the minor
\[
\begin{vmatrix} h_6 & h_7 \\ h_1 & h_2 \end{vmatrix}
\]
can be found in $A_2$ but not $A_3$; however, we can write
\[
\begin{vmatrix} h_6 & h_7 \\ h_1 & h_2 \end{vmatrix} = \begin{vmatrix} h_5 & h_7 \\ h_1 & h_3 \end{vmatrix} - \begin{vmatrix} h_5 & h_6 \\ h_2 & h_3 \end{vmatrix},
\]
where the minors on the right hand side can be found in $A_3$. One can see that trying to do this systematically for $k \times k$ minors with $k \geq 3$ gets rather difficult.

Since minors are rather difficult to work with directly, we instead use Schur polynomials. The complete homogeneous symmetric polynomials in $n$ variables $x_1, \ldots, x_n$ are the polynomials
\[
h_0(x_1, \ldots, x_n) = 1
\]
\[
h_1(x_1, \ldots, x_n) = \sum_{1 \leq i \leq n} x_i
\]
\[
h_2(x_1, \ldots, x_n) = \sum_{1 \leq i < j \leq n} x_ix_j
\]
\[
h_3(x_1, \ldots, x_n) = \sum_{1 \leq i < j < k \leq n} x_ix_jx_k
\]
\[
\vdots
\]
where $h_d(x_1, \ldots, x_n)$ is the sum of all monomials of total degree $d$. What these polynomials actually are is not so important to our proof; the importance lies in the fact that $h_1, \ldots, h_n$ are algebraically independent. An integer partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ of $n$ is a non-increasing sequence of nonnegative integers $\lambda_i$ such that $\sum \lambda_i = n$. If $k$ is the largest number such that $\lambda_k > 0$, then we say $\lambda$ has $k$ parts. If $\lambda_i \leq \ell$, we say that the $i$-th part of $\lambda$ is at most $\ell$. If $\lambda$ has $k$ parts and $\lambda_1 \leq \ell$, then we say that $\lambda$ fits in a $k \times \ell$ box. We associate to each integer partition $\lambda$ a Young diagram (see Figure\[1\]).
If \( \lambda \) and \( \mu \) are two partitions and \( \mu_i \leq \lambda_i \) for all \( i \), then we say \( \mu \) is contained in \( \lambda \). If so, then we associate a skew diagram to \( \lambda \mod \mu \), written \( \lambda/\mu \) (see Figure 2).

To any such \( \lambda/\mu \), we associate the Schur polynomial

\[
S_{\lambda/\mu} = \det (h_{\lambda_i-\mu_j-i+j})
\]

where we take \( \mu_k = 0 \) if \( \lambda \) has \( k \) parts. Schur polynomials correspond to minors found in Toeplitz matrices, which is precisely what we need. For a more comprehensive treatment of Schur polynomials and Young diagram, we refer the reader to [5]. A Schur polynomial \( S_{\lambda/\mu} \) is non-skew if \( \mu = 0 \), and skew otherwise.

Our primary weapon of attack will be the Littlewood-Richardson rule, which tells us how to decompose a skew Schur polynomial into a linear combination of non-skew Schur polynomials (with positive coefficients, even!). Suppose \( S_{\lambda/\mu} \) is a skew Schur polynomial. Draw the diagram associated with \( \lambda/\mu \). A labeling of \( \lambda/\mu \), where \( \lambda \) has \( k \) parts, is defined as a labeling of the squares of the diagram with integers 1, \ldots, \( k \) such that:

- the numbers are weakly increasing from left to right in each row;
- the numbers are strictly increasing from top to bottom in each column;
- when reading the string of the numbers from right to left in each row, top row to bottom row, each initial substring must have at least as many \( i \)'s as \( i+1 \)'s, for all \( i \).

The first two properties say that the labeling forms a skew semistandard Young tableau. A partition \( \pi \) arises from a labeling of \( \lambda \) if, for each \( i \), the \( i \)-th part of \( \pi \) has size equal to the number of \( i \)'s in the labeling of \( \lambda \). The Littlewood-Richardson rule states that

\[
S_{\lambda/\mu} = \sum_\pi S_\pi
\]

where the sum is over all partitions \( \pi \) that arise from a labeling of \( \lambda/\mu \) (see Figure 3 for an illustration of this rule).

Since the Schur polynomials \( h_1, \ldots, h_n \) in \( n \) variables are algebraically independent, we may treat the Littlewood-Richardson rule as an algebraic identity for \( S_{\lambda/\mu} \) of the form (3), where the \( h_i \) are formal variables.
Recall our definition of the matrix $A$ and its submatrices $A_c$ in the statement of the Lemma. We now introduce a new term:

**Definition 3.2.** A Schur polynomial $S_{\lambda/\mu}$ is $(k, c)$-legal if it is equal to a $k \times k$ minor in $A_c$. We also say that $\lambda/\mu$ is $(k, c)$-legal, if $S_{\lambda/\mu}$ is $(k, c)$-legal, identifying the polynomial with the diagram.

By this definition, our task amounts to proving that the ideal generated by $(k, k)$-legal diagrams is equal to the ideal generated by $(k, c)$-legal diagrams, for all $1 \leq k \leq n$ and for all $k \leq c \leq \frac{n^2}{2}$. To make our job easier, we have the following characterization:

**Proposition 3.3.** A skew diagram $\lambda/\mu$ with $k$ parts is $(k, c)$-legal if and only if the following hold:

- $\lambda_1 \leq n - k + 1$;
- $\lambda_k \geq k$;
- $\mu_1 \leq c - k$;
- $\lambda_i - \mu_i \geq k$ for all $i$;
- $\lambda_1 - \lambda_k \leq n - c - k + 1$.

**Proof.** Suppose $\lambda/\mu$ is $(k, c)$-legal. Then it corresponds to some $k \times k$ minor

\[
\begin{vmatrix} h_{i+t} & \cdots & h_{i+t+r} \\ \vdots & \ddots & \vdots \\ h_i & \cdots & h_{i+r} \end{vmatrix}
\]

of $A_c$, where the rows and columns represented by dots are not necessarily adjacent in $A$. Recall that

\[
A_c = \begin{pmatrix} h_{n-c+1} & \cdots & h_n \\ \vdots & \ddots & \vdots \\ h_1 & \cdots & h_c \end{pmatrix}.
\]

This implies that

- $1 \leq i \leq n - k - c + 2$,
- $k - 1 \leq r \leq c - 1$,
- $k - 1 \leq t \leq n - c$,
- $k \leq i + t \leq n - c + 1$,
- $k \leq i + r \leq c$,
- $2k - 1 \leq i + t + r \leq n$.

From Eq. (3), we find that

\[
\lambda = (i + t + r - k + 1, \ldots, i + r) \\
\mu = (r - k + 1, \ldots, 0).
\]
Therefore
\[
\begin{align*}
\lambda_1 &= i + t + r - k + 1 \leq n - k + 1, \\
\lambda_k &= i + r \geq k, \\
\mu_1 &= r - k + 1 \leq c - k, \\
\lambda_1 - \lambda_k &= t - k + 1 \leq n - c - k + 1.
\end{align*}
\]

The remaining inequality, \(\lambda_i - \mu_i \geq k\), follows from the fact that the diagonal terms of the submatrix must be at least \(k\), and are equal to the \(\lambda_i - \mu_i\).

Now suppose \(\lambda/\mu\) satisfies the above inequalities. It is straightforward to verify that the \(k \times k\) minor with entries
\[
\begin{vmatrix}
h_{\lambda_1 - \mu_1} & * & \cdots & * \\
* & h_{\lambda_2 - \mu_2} & \cdots & * \\
 & \ddots & \ddots & \\
* & * & \cdots & h_{\lambda_k - 1 - \mu_{k-1}} & h_{\lambda_k - 1 + 1} \\
* & * & \cdots & * & h_{\lambda_k}
\end{vmatrix}
\]
(where the \(\ast\) denote entries that are determined by the choice of rows and columns) corresponds to \(\lambda/\mu\) and can be found in \(A_c\). \[\square\]

**Corollary 3.4.** The \((k, k)\)-legal diagrams are precisely non-skew \(\lambda\) such that \(\lambda_1 \leq n - k + 1\) and \(\lambda_k \geq k\).

Before we begin proving Lemma 2.6, we make the following handy definition:

**Definition 3.5.** If \(\lambda\) has \(k\) parts, then the **spread** of \(\lambda\) is the integer partition

\[(\lambda_1 - \lambda_k, \lambda_2 - \lambda_k, \ldots, \lambda_{k-1} - \lambda_k)\]

We put a lexicographical well-ordering on spreads. That is, if \(\delta = (\delta_1, \ldots, \delta_{k-1})\) and \(\epsilon = (\epsilon_1, \ldots, \epsilon_{k-1})\) are spreads, then \(\delta < \epsilon\) if and only if the leftmost nonzero entry of \(\epsilon - \delta\) is positive.

With this definition in mind, we prove our main lemma, which can be seen as an “inverse” Littlewood-Richardson rule:

**Lemma 3.6.** Any \((k, k)\)-legal diagram is a linear combination of \((k, c)\)-legal diagrams.

**Proof.** Suppose \(\nu\) is a \((k, k)\)-legal diagram. If \(\nu_1 - \nu_k \leq n - c - k + 1\), then by Proposition 3.3, \(\nu\) is \((k, c)\)-legal. If \(\nu_1 - \nu_k > n - c - k + 1\), then its spread exceeds \((n - c - k + 1, n - c - k + 1, \ldots, n - c - k + 1)\).

We construct the following skew diagram \(\lambda/\mu\) (see Figure 4):

**Figure 4.** An example of constructing a \(\lambda/\mu\) from a given non-skew \(\nu\).
Finally, we can prove Lemma 2.6.

Proof of Lemma 2.6. Let \( 1 \leq k \leq c \leq \frac{n}{2} \). We first show that any \((k,c)\)-legal diagram is a linear combination of \((k,k)\)-legal diagrams. Suppose \(\lambda/\mu\) is \((k,c)\)-legal. By Proposition 3.3, \(\lambda_1 \leq n-k+1\) and \(\lambda_k \geq k\). If \(\lambda/\mu\) is non-skew, i.e. \(\mu = 0\), then by Corollary 3.4 \(\lambda/\mu\) is \((k,k)\)-legal. If \(\lambda/\mu\) is skew, then we use the Littlewood-Richardson rule to write it as a sum of non-skew diagrams. Any labeling of \(\lambda/\mu\) must have at most \(n-k+1\) copies of 1, since there are at most \(n-k+1\) columns and each column can have at most one 1. Thus \(\nu_1 \leq n-k+1\) for all \(\nu\) arising from a labeling. Similarly, a labeling must have at least \(\lambda_k - \mu_1\) copies of \(k\), since this is equal to the number of columns with length \(k\). But if \(\lambda/\mu\) is associated to the minor in Eq. 4, then \(\lambda_k - \mu_1 = i + r - (r - k + 1) = i + k - 1 \geq k\). Therefore \(\nu_k \geq k\) for all \(\nu\) arising from a labeling. By Corollary 3.4, \(\lambda/\mu\) is a sum of \((k,k)\)-legal diagrams.

The other inclusion follows from Lemma 3.6. \(\square\)

4. Proof of Theorem 1.2

A plane partition of a positive integer \(n\) is a finite two-dimensional array of positive integers, weakly decreasing from left to right and from top to bottom, with sum \(n\). For example, a plane partition of 43 could be

\[
\begin{array}{cccccc}
5 & 4 & 4 & 3 & 2 \\
4 & 4 & 3 & 3 & 2 \\
2 & 2 & 1 & 1 \\
1 & 1 \\
1
\end{array}
\]

For more information on plane partitions, see [3] for a more comprehensive treatment.

We say that a plane partition fits inside an \(a \times b \times c\) box if there are at most \(a\) rows, at most \(b\) columns, and each entry is at most \(c\). For instance, the example above fits in an \(a \times b \times c\) box for \(a,b,c = 5\). This terminology stems from the fact that there is a natural way to view a plane partition as cubes stacked against the corner of the first octant in \(\mathbb{R}^3\).

Let \(\text{PP}(a,b,c)\) denote the number of plane partitions that fit in an \(a \times b \times c\) box. MacMahon found the following elegant formula:

\[
(5) \quad \text{PP}(a,b,c) = \prod_{i=1}^{a} \prod_{j=1}^{b} \prod_{k=1}^{c} \frac{i + j + k - 1}{i + j + k - 2}.
\]

A proof of this formula can be found in [3]. Li and Zanello essentially prove Theorem 1.2 in [10] by directly verifying that \(|\det U_r|\) equals the right hand side of (4). In this section, we give a bijective proof of this result. Recall the statement of Theorem 1.2.
Figure 5. The plane partition \{(5, 4, 4, 3, 2), (4, 4, 3, 3, 2), (2, 2, 1, 1), (1, 1), (1)\} in a 5 × 5 × 5 box.

**Theorem.** Expressed in the monomial \(\mathbb{Z}\)-basis for \(\mathbb{R} = \mathbb{Z}[x, y, z]/(x^{a+b}, y^{a+c}, z^{b+c})\) the map \(U_m : R_m \rightarrow R_{m+1}\) has its determinant \(\det(U_m)\) equal, up to sign, to its permanent \(\text{perm}(U_m)\), and each nonzero term in its permanent corresponds naturally to a plane partition in an \(a \times b \times c\) box.

**Proof.** Our proof consists of two steps. First, we show that the number of plane partitions in an \(a \times b \times c\) box is equal to the permanent of \(U_r\). For ease of notation, let \(U = U_r\). Let \(B_s\) denote the monomial basis of \(R_s\) as before. Recall that the permanent of \(U\) equals \(\sum_{\phi} \prod_{\lambda \in B_r} U_{\lambda, \phi(\lambda)}\) where the sum is over all bijections \(\phi : B_r \rightarrow B_{r+1}\) and \(U_{\lambda, \mu}\) denotes the entry in row \(\lambda\), column \(\mu\) of the matrix representing \(U\). Viewing the elements of \(B_r \cup B_{r+1}\) as vertices of a bipartite graph, with \(B_r\) as one part and \(B_{r+1}\) as the other, and each 1 in the matrix of \(U\) corresponding to an edge, we see that each such \(\phi\) gives rise to a perfect matching if \(U_{\lambda, \phi(\lambda)} = 1\) for all \(i \in B_r\). Since \(U\) is a 0-1 matrix, the permanent of \(U\) counts the number of perfect matchings in this bipartite graph.

**Step 1: Perfect matchings to plane partitions.** Draw an equilateral triangle with side length \(a + b + c\), and insert the monomials of \(k[x, y, z]\) of degree \(r + 1 = a + b + c - 1\); Figure 6 illustrates the case of \(r = 3\).

Fill the remaining spaces with the monomials of degree \(r = a + b + c - 2\) as in Figure 7 notice that two monomials in the diagram are adjacent if and only if one divides the other.

Now truncate the equilateral triangle by removing a triangle of length \(c\) from the top corner, a triangle of length \(b\) from the lower left corner, and a triangle of length \(a\) from the lower right corner. We are left with an \(a \times b \times c\) hexagon containing the monomials in \(B_r \cup B_{r+1}\), the vertices of the bipartite graph mentioned in the previous paragraph. Figure 8 shows the hexagon for \((a, b, c) = (2, 2, 1)\). Figure 9 shows this hexagon with monomials in \(B_r\) as black dots and monomials in \(B_{r+1}\) as white dots. A perfect matching between \(B_r\) and \(B_{r+1}\) is a bijection such that for any \(\lambda \in B_r\), \(\lambda\) and its image are adjacent in the hexagon, i.e., they lie in adjacent equilateral triangles.

We can thus represent a perfect matching pictorially as in Figure 9. It is thus evident that there is a bijection between perfect matchings and rhombus tilings of this \(a \times b \times c\) hexagon. But the bijection between such rhombus tilings and plane partitions in an \(a \times b \times c\) box is well-known; we view the tiling as a three-dimensional picture of the plane partition (rotated by 90°). Hence, the number of perfect matchings is equal to the number of such plane partitions, as desired.
Step 2: Permanent equals determinant. Consider the bijection between perfect matchings and plane partitions given above. To get from one plane partition to another, we perform the operations of adding or removing a block. For example, Figure 10 shows the plane partition with the right-most block removed (or added, depending on perspective, but we fix perspective at the beginning).

As Figure 10 shows, if $\varphi$ is the perfect matching associated with a plane partition, the associated perfect matching after such an operation is $\sigma \varphi$, where $\sigma$ is a 3-cycle. Note that $\sigma$ is an even permutation; hence, we can get from any perfect matching to another using even permutations. This shows that all perfect matchings have the same sign, completing the proof. \[\square\]
Figure 8. Truncating equilateral triangle

Figure 9. Left: Simplified diagram. Right: A perfect matching viewed as a plane partition

5. Proofs of Theorems 1.3, 1.4, and 1.5

In [3], Bressoud describes the ten symmetry classes of plane partitions that are of interest. Each class consists of plane partitions that are invariant under certain actions. Each of these actions is some composition $\rho^i\tau^j\kappa^k$ where $(i,j,k) \in \{0,1\}^3$, $\rho$ is cyclically permuting the three coordinate axes, $\tau$ is reflection across the $y = z$ plane, and $\kappa$ is complementation. Viewing plane partitions as rhombus tilings in the plane, it is straightforward to check that $\rho$ acts by counterclockwise rotation by $120^\circ$, $\tau$ acts by reflection about the vertical axis of symmetry, and $\kappa$ acts by rotation by $180^\circ$. Note that $\langle \rho, \tau, \kappa \rangle = D_{12}$, the dihedral group of order 12, which is the group of symmetries on a regular hexagon. Given the above bijection, each symmetry class of plane partitions can be viewed as a subset of perfect matchings of the aforementioned bipartite graphs which are invariant under...
some subgroup of $D_{12}$. The ten symmetry classes are enumerated in Figure 11 in the same order as in [3].

| Number | Class                                                                 | Abbreviation | Subgroup |
|--------|----------------------------------------------------------------------|--------------|----------|
| 1      | Plane partitions                                                     | PP           | ⟨e⟩      |
| 2      | Symmetric plane partitions                                           | SPP          | ⟨τ⟩      |
| 3      | Cyclically symmetric plane partitions                                | CSPP         | ⟨ρ⟩      |
| 4      | Totally symmetric plane partitions                                   | TSPP         | ⟨ρ, τ⟩   |
| 5      | Self-complementary plane partitions                                  | SCPP         | ⟨κ⟩      |
| 6      | Transpose complement plane partitions                                | TCPP         | ⟨τκ⟩     |
| 7      | Symmetric self-complementary plane partitions                        | SSCPP        | ⟨τ, κ⟩   |
| 8      | Cyclically symmetric transpose complement plane partitions           | CSTCPP       | ⟨ρ, τκ⟩  |
| 9      | Cyclically symmetric self-complementary plane partitions             | CSSCPP       | ⟨ρ, κ⟩   |
| 10     | Totally symmetric self-complementary plane partitions                | TSSCPP       | ⟨ρ, τ, κ⟩|

**Figure 11.** The symmetry classes of plane partitions

We have shown that, for $R = k[x, y, z]/(x^a+b, y^a+c, z^b+c)$ and $r = a + b + c - 2$, we have $| \det U_r | = \text{PP}(a, b, c)$. In this section, we show that, for certain natural submodules of $R$ over various invariant subrings (for appropriate group actions in each case), the determinant of the restriction of $U_r$ to the submodule is equal (up to sign) to the number of a symmetry class of plane partitions that fit in an $a \times b \times c$ box.
Proof of Theorem 1.3. Recall the statement of Theorem 1.3.

**Theorem.** Assuming \( a = b = c \), let \( C_3 = \mathbb{Z}/3\mathbb{Z} = \{ 1, \rho, \rho^2 \} \) act on \( R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{2a}, z^{2a}) \) by cycling the variables \( x \overset{\rho}{\rightarrow} y \overset{\rho^2}{\rightarrow} z \overset{\rho}{\rightarrow} x \). Then the map \( U_m\vert_{R_{C_3}} \) restricted to the \( m \)-th homogeneous component of the \( C_3 \)-invariant subring \( R_{C_3} \) has \( \det(U_m\vert_{R_{C_3}}) \) equal, up to sign, to the number of cyclically symmetric plane partitions in an \( a \times a \times a \) box.

**Proof.** The proof is in the same spirit as our proof for vanilla plane partitions: we show that the permanent of \( U'_r \) is equal to the cyclically invariant perfect matchings (which correspond to cyclically symmetric plane partitions), and then show that the permanent equals the determinant up to sign.

The elements \( x^iy^jz^k + y^iz^jx^k + z^ix^jy^k \) form a basis for \( R^\rho \). Hence, \( U'_r \) can be realized as a matrix with columns indexed by the basis elements of rank \( r \) of \( R^\rho \), and rows indexed by the basis elements of rank \( r + 1 \) of \( R^\rho \).

The element \( \rho \) acts on the hexagonal bipartite graph \( G \) by rotation by 120 degrees, so we can consider the quotient graph \( G/\langle \rho \rangle \), where the vertices and edges are \( \langle \rho \rangle \)-orbits of vertices and edges in \( G \), respectively. Figure 12 shows an example of the honeycomb graph and its corresponding quotient graph when \( a = b = c = 2 \).

Since \( r = 3a - 2 \equiv 1 \pmod{3} \) and \( r + 1 \equiv 2 \pmod{3} \), no monomial in either rank is fixed under \( \rho \). It follows that each vertex and edge orbit correspond to three vertices and edges in \( G \), respectively. Hence, cyclically symmetric perfect matchings on \( G \) correspond to perfect matchings on \( G/\langle \rho \rangle \).

Moreover, there is a natural correspondence between the vertices in the quotient graph and the basis elements of the two middle ranks. Depending on the context, we will abuse notation and write \( [i, j, k] \) to mean both a vertex orbit \( [x^iy^jz^k] \) or a basis element \( x^iy^jz^k + y^iz^jx^k + z^ix^jy^k \).

In the quotient graph, every vertex orbit \( [i, j, k] \) is connected to \( [i+1, j, k] \), \( [i, j+1, k] \) or \( [i, j, k+1] \) (if those orbits exist), and similarly, \( U'_r \) sends any basis element \( [i, j, k] \) to a sum of basis elements \( [i+1, j, k] + [i, j+1, k] + [i, j, k+1] \) (if those elements exist.)

Note that the orbits \( [a, a, a - 1] \) and \( [a, a - 1, a - 1] \) share two edges in the quotient graph. The only way for two orbits to share two edges is if all elements of both orbits entirely make up the vertices of a hexagon in \( G \). Hence, only the middle hexagon gives rise to this double edge in the
quotient graph. Likewise, as basis elements, $U'_r[a, a - 1, a - 1] = [a + 1, a - 1, a - 1] + 2 \cdot [a, a, a - 1]$, and $[a, a - 1, a - 1]$ is the only element that gets sent to two times another basis element. Hence, $U'_r$ is the adjacency matrix of $G/\langle \rho \rangle$. The number of perfect matchings on $G/\langle \rho \rangle$ is equal to the permanent of $U'_r$ (by treating the sole 2 in $U'_r$ as the two possible ways to have $[a, a - 1, a - 1]$ and $[a, a, a - 1]$ connected in a perfect matching), and it follows that the permanent of $U'_r$ equals the number of cyclically symmetric plane partitions.

Next, we show that the permanent equals the determinant up to sign by showing all the matchings of $G/\langle \rho \rangle$ have the same sign. To get from a cyclically symmetric partition to one with fewer blocks, we can remove three blocks in the same orbit, or remove the block in the center of the partition. If $\varphi$ is the perfect matching in $G/\langle \rho \rangle$ that corresponds to the partition, the partition after removing three blocks in the same orbit corresponds to $\sigma \varphi$, where $\sigma$ is a 3-cycle, so this operation doesn’t change the sign of the matching. Removing the central block corresponds to switching the edge between $[a, a - 1, a - 1]$ and $[a, a, a - 1]$ to the other edge, and thus does not change the sign. Figure 13 gives an example of these removals in action.

The signs of all the matchings in $G/\langle \rho \rangle$ are the same, so the permanent is equal to the determinant up to sign, and the result follows.

**Proof of Theorem 1.4** Recall the statement of Theorem 1.4.

**Theorem.** Assuming $a = b$ and the product $abc$ is even, let $C_2 = \mathbb{Z}/2\mathbb{Z} = \{1, \tau \kappa\}$ act on $R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{a+c}, z^{a+c})$ by swapping $y \leftrightarrow z$. Then the map $U_m|_{R^{C_2}}$ restricted to the $m$-th homogeneous component of the anti-invariant submodule $R^{C_2,-} := \{ f \in R : \tau \kappa(f) = -f \}$ has $\det(U_m|_{R^{C_2,-}})$ equal, up to sign, to the number of transpose complementary plane partitions in an $a \times a \times c$ box.

**Proof.** This time, the transpose complementary plane partitions correspond to perfect matchings on $G$ that are symmetric about the vertical axis of symmetry (flip symmetric). Note that all the vertices on the vertical axis are of the form $x^iy^jz^k$, and in any symmetric perfect matching, $x^iy^jz^k$ must be matched with $x^{i+1}y^jz^k$ to preserve flip symmetry.

On $G/\langle \tau \kappa \rangle$, erase all vertices $[i, j, j]$ and all edges coming out of them. Call this new graph $G'$. From flip symmetry and our previous observation, flip symmetric matchings on $G$ correspond directly to matchings on $G'$. Figure 14 gives an example of $G'$ when $a = b = c = 2$.

Moreover, every vertex $[x^iy^jz^k]$ of $G'$ corresponds to two elements $x^iy^jz^k$ and $x^i z^j y^k$. These vertices are in bijection with $x^iy^jz^k - x^i z^j y^k$ ($j > k$), the basis elements of $R^{C_2}$. Again, we abuse
notation and let \([i, j, k]\) represent either a vertex of \(G'\) or a basis element depending on context.
In \(G'\), every vertex orbit \([i, j, k]\) is connected to \([i + 1, j, k]\), \([i, j + 1, k]\) or \([i, j, k + 1]\) (if those orbits exist), and similarly, \(U_r\) sends any basis element \([i, j, k] (j > k)\) to a linear combination of basis elements \([i + 1, j, k]\) + \([i, j + 1, k]\) + \([i, j, k + 1]\) (if those elements exist.) Notice if \(k + 1 = j\), then \([i, j, k + 1]\) = 0.
Hence, \(U'_r\), realized as a matrix indexed by the basis elements of rank \(r\) and \(r + 1\), is the adjacency matrix for \(G'\), and has entries in \([0, 1]\). Therefore the permanent of \(U'_r\) counts the number of flip symmetric perfect matchings in \(G\).
To show permanent equals determinant, we show matchings in \(G'\) have the same sign. To get from one transpose complementary plane partition to another, we move a visible block (meaning three sides of the block are visible) to its transpose complementary location (which is empty by symmetry.) This corresponds to hitting the perfect matching on \(G'\) with a three cycle, so this preserves sign. All the transpose complementary plane partitions are connected in this way because we can transform them into the basic transpose complementary plane partition where the top layer of blocks is level (see the right plane partition in Figure 15.) Hence, every matching on \(G'\) has the same sign, making the permanent equal the determinant.

\[\square\]

Proof of Theorem 1.5 Recall the statement of Theorem 1.5:

Theorem. Assuming \(a = b = c\) are all even, let \(C_2, C_3\) act on \(R = \mathbb{Z}[x, y, z]/(x^{2a}, y^{2a}, z^{2a})\) as before. Then the map \(U_m|_{R^{C_2} \cap R^{C_3}}\) restricted to the \(m\)-th homogeneous component of the intersection \(R^{C_2} \cap R^{C_3}\) has \(\det(U_m|_{R^{C_2} \cap R^{C_3}})\) equal, up to sign, to the number of cyclically symmetric transpose complementary plane partitions in an \(a \times a \times a\) box.

Proof. This is a hybrid of the two previous proofs: the basis elements are now \(x^iy^jz^k - x^iz^ky^j + y^ix^jz^k - z^ix^jy^k\) and now we move three visible blocks in the same \(\rho\) orbit to their transpose complementary locations to get from one CSTCPP to another. \(\square\)
Figure 15. Moving visible block to its transpose complementary location

6. Questions

Question 6.1. Is there some way to determine the Smith entries for the middle map $U_{\lfloor e^{-1/2} \rfloor}$ for $R$, and is there a combinatorial explanation for the Smith entries in the context of plane partitions when $A = a + b$, $B = a + c$, and $C = b + c$?

Question 6.2. Why does the extension of Theorem 1.1 seem to work for four variables but not for five variables?

Question 6.3. Is there some way to achieve the counts for the other symmetry classes of plane partitions as determinants of maps like $U_r$ restricted to natural submodules of $R$?

Acknowledgements

This research was performed in a summer REU at the University of Minnesota, mentored by Vic Reiner and Dennis Stanton, supported by NSF grant DMS-1001933. The authors thank Vic Reiner and Dennis Stanton for their immense guidance, without which none of this research would have been possible.
