Abstract
Titanium dioxide (TiO\textsubscript{2}) is one of the most applied nanomaterial and widely used in different food and non-food products as additive or coating material. In vitro and in vivo studies have shown that TiO\textsubscript{2} nanoparticles (NPs) induce cytotoxicity and inflammation in Caco-2 cells, but the detailed mechanisms how TiO\textsubscript{2} NPs interact with the cell and mediate their inflammatory potential remains unclear. Our recent studies on Caco-2 cells have shown that exposure to TiO\textsubscript{2} NPs induce an inflammatory response via an epidermal growth factor receptor (EGFR)-mediated pathway. In the current study we demonstrate that 10 nm TiO\textsubscript{2} NPs induce the activation of extracellular signal-regulated kinases (ERK) and the expression of ERK target genes Chemokine (C-C motif) ligand 3 (CCL2) and Chemokine (C-X-C motif) ligand 3 (CXCL3). This activation is dependent on EGFR, as treatment of EGFR kinase inhibitor BIBX 1382 attenuates phosphorylation of ERK1/2 and the mRNA expression of CCL2 and CXCL3. Moreover, TiO\textsubscript{2} NPs induce the activation of the transcription factor ERK1. We thus suggest TiO\textsubscript{2} NPs induce an EGFR/ERK/ELK1-mediated pathway.

Introduction
Titanium dioxide (TiO\textsubscript{2}) is one of the most applied nanomaterial and widely used in the food and non-food industry as additive or coating material [1]. TiO\textsubscript{2} nanoparticles (NPs) are characterized by its high refractive index, photo catalytic activity and stability and thus used as white pigment in cosmetics, personal care products, paints, coatings, or in food and pharmaceuticals as additive E171. Additionally, TiO\textsubscript{2} NPs are used in water and air purification or medical applications because of its photo catalytic and antibacterial attributes [2,3].

Because of their ability to induce inflammation, cytotoxicity and genotoxicity in different cell types \textit{in vitro} and \textit{in vivo} [5] the effect of TiO\textsubscript{2} NPs on gut homeostasis is a major concern [6]. Studies using the human colon carcinoma cell line Caco-2 have shown that TiO\textsubscript{2} NPs induced oxidative damage [7] influenced metabolic activity and cytotoxicity [8,9] produced reactive oxygen species (ROS) [10,11] and finally induced the expression of Interleukin 8 (IL8) [12] in part, through the activations of nuclear factor (NF)-kB and p38 mitogen activated protein kinase (MAPK) pathways [13].

Moreover, our recent findings have shown that cellular response to TiO\textsubscript{2} NPs in Caco-2 cells are dependent on the activation of epidermal growth factor receptor (EGFR), mediated by endocytosis-related structures [12]. The underlying precise signaling cascade between EGFR activation and expression of different inflammatory markers in intestinal epithelial cells remains unknown. Studies on various cell lines declare effects to TiO\textsubscript{2} NPs on signaling pathways such as p38 MAPK and extracellular signal-regulated kinases 1/2 (ERK 1/2) in neutrophils [22], c-Jun N-terminal kinases (JNK)/p38-caspase-8-Bid pathway in lymphocytes [23], NF-κB pathway in kidney cells of mice [24] apoptotic pathways in bronchial epithelial cells via activation of caspase-8 and -3, -7 [25] and mitochondrial-mediated pathways in mouse splenocytes [26]. In macrophage-like cells TiO\textsubscript{2} NPs response is depended on active cathepsin B [27] and in breast, lung and liver cells by Fas upregulation and Bax activation [28]. Induction of these pathways and expression of downstream genes such as IL8 or IL-1β, are initiated by the generation of ROS or via binding of TiO\textsubscript{2} NPs to TLR4 at the cell membrane and further activation of NF-κB [14,29].

Besides these findings, studies using different types of NPs have shown...
an activation of the ERK signaling pathway [30,31] with a previous activation of EGFR in epithelial cells [32-36].

So far, there has been no evidence for TiO₂ NP-induced inflammatory response through EGFR activation and further induction of ERK signaling pathway and downstream mediators in Caco-2 cells. In the current study, Caco-2 cells were exposed to 10 nm TiO₂ NPs which induce an initial activation of ERK1/2 and the ERK-related transcription factor Elk1. This activation was accompanied with an increased expression of Chemokine (C-C motif) ligand 2 (CCL2) and Chemokine (C-X-C motif) ligand 3 (CXCL3) genes. We could further demonstrate that TiO₂ NP-induced ERK1/2 signaling is mediated through EGFR activation and increased after IκB-a inhibition.

**Material and methods**

**Preparation of TiO₂ NPs**

The preparation and characterization of the used TiO₂ NPs were described in our previous study [13]. Briefly, titanium (IV) dioxide (anatase) particles were obtained from Alfa Aesar (Alfa Aesar GmbH & Co KG, Germany). Particles were used with a nominal size of 10 nm (Stock Number 44690, Lot B19T020; specific surface area 120 m² g⁻¹) and a measured size of 14.4 nm [13]. The particles form agglomerates in a size of 673 × 455 nm [13]. Stock solution was prepared with deionized water to a final concentration of 2 mg mL⁻¹. The dispersion was sonicated at 23 KHZ and 150 W (MSE Ltd, United Kingdom) for two minutes and finally autoclaved. Immediately before treatment of the cells, the dispersion was diluted in cell culture medium as indicated below.

**Cell culture**

Human colon adenocarcinoma cell line Caco-2 (Toni Lindl, Munich, Germany) between passage 34 and 52 were used in this study. Cells were cultured in Caco-2 medium (45% Dulbecco’s Modified Eagle Medium (DMEM), low glucose, 45% Ham’s F12, 9% FCS, 0.9% non-essential amino acids (all PAA Laboratories GmbH, Austria) and Insulin (10 μg mL⁻¹) (Biochrome AG, Germany)) at 37°C and 5% CO₂.

**Western blot analyses**

Caco-2 cells were seeded in 6-well plates (8.87 cm² per well) (Sarstedt, Germany) at a density of 1-2×10⁵ cells cm⁻². At confluency, prepared medium with 10 nm TiO₂ NPs were added to the cells at a final concentration of 40 μg cm⁻² cell growth surface or remain untreated. After indicated incubation time cells were washed twice with cold PBS and lysed 20 min on ice in RIPA buffer (Sigma-Aldrich, U.S.) and visualized with Fusion solo S (Vilber Lourmat Deutschland GmbH, Germany) at a density of 1-2×10⁵ cells cm⁻². At confluency, cells were stimulated with 10 nm TiO₂ NPs at a final concentration of 40 μg cm⁻² cell growth surface or remain unstimulated. After indicated time cells were washed twice with ice cold PBS and lysed 20 min on ice in lysis buffer (10 mM HEPES, 1.5 mM MgCl₂, 10 mM KCl, 1 mM DTT, 1 mM PMSF, 1x complete protease inhibitor cocktail (Santa Cruz Biotechnology, U.S.)) adapted from [37]. Cells were scraped, placed in a microtube and centrifuged at 20,000 g at 4°C to separate cytosolic and nuclear fractions. Supernatant was decanted and pellet was suspended in extraction buffer to lyse nuclei (20 mM HEPES, 1.5 mM MgCl₂, 0.42 M NaCl, 0.2 mM EDTA, 25% (v/v) glycerol, 1 mM DTT, 1 mM PMSF, 1x complete protease inhibitor cocktail (Santa Cruz Biotechnology, U.S.)) and visualized with FusionCapt Advance Solo 4s software and quantified with Fusion solo S (Vilber Lourmat Deutschland GmbH, Germany).

**Immunocytochemistry**

Caco-2 cells were seeded in removable 12-well chambers (ibidi GmbH, Germany) at a density of 1-2×10⁵ cells cm⁻². At confluence prepared medium with 10 nm TiO₂ NPs were added to the cells at a final concentration of 40 μg cm⁻² cell growth surface or remain untreated. After indicated incubation time cells were washed with PBS and fixed with cold 4% paraformaldehyde in PBS for 30 min. After washing, cells were permeabilized with 0.1% Triton X-100 in PBS for 10 min and blocked with 10% donkey serum in PBS for 1 h. Primary antibody p-ERK1/2 (sc-7383, Santa Cruz Biotechnology, U.S.) was diluted 1:100 in PBS and cells were incubated overnight at 4°C. Following PBS wash, cells were incubated 1 h at RT with secondary antibody Alexa Fluor 546 (A10036, Molecular Probes®, U.S.) 1:200 in 10% donkey serum in PBS. After washing with PBS cells were mounted with Dapi-Fluoromount-G™ clear mounting media (Southern Biotech, U.S.). Pictures were acquired with a confocal laser scanning microscope TCS SP8 (Leica Microsystems GmbH, Germany).

**mRNA expression analysis**

For mRNA expression analysis cells were seeded in 24-well or 6-well culture plates (Sarstedt AG & Co., Germany) at a density of 1-2×10⁵ cells cm⁻². After reaching confluency, 10 nm TiO₂ particles were added at a final concentration of 40 μg cm⁻² cell growth surface or remain untreated. At indicated time points cells were washed twice with PBS and proceed to RNA extraction. RNA was extracted using the GeneJET RNA isolation kit.
Purification Kit (Thermo Fisher Scientific GmbH, Germany) and first strand cDNA synthesis was prepared using RevertAid<sup>E</sup> H Minus First Strand cDNA Synthesis Kit (Thermo Fisher Scientific GmbH, Germany) as described by the manufacturer. Real-time PCR was performed on a 7500 Real-Time PCR Systems (Life Technologies Inc., U.S.) using HOT FIREPol EvaGreen<sup>®</sup> qPCR Mix Plus ROX (Solis BioDyne, Estonia). Sequences of primers (used at 0.2 µM) were as follows: B2M (Beta-2 microglobulin) forward: GCAAAGCTGTCCTTTCTATCT, reverse: TAACATCTTGGCGTGTGACA; CCL2 (Chemokine (C-C motif) ligand 2) forward: CCCAAGAGCCTGATCTCTCA; reverse: TGTGGGAAAGCTAGGGAAG, CXCL3 (chemokine (C-X-C motif) ligand 3) forward: CCAAAACCGAAGTCATAGCCA, reverse: ACCCTGCAAGAAGTGCTCA; GAPDH (Glyceraldehyde-3-phosphate dehydrogenase) forward: AGACACACAGAGAAGAGAGAG, reverse: GTGTGACACAGGGGTACCTATT. Parameters for qPCR were: 95°C for 15 min, 40 cycles of 10 s 95°C, 30 s 60°C and 30 s 72°C. After cycling, melting curve analysis was performed. Expressions of the different genes was normalized to the expressions of GAPDH and B2M and compared to control using delta delta Ct method [39]. Experiments were performed four times.

Cells treatment

Inhibitor of IκB-α phosphorylation Bay11-7082 (InvivoGene, USA), inhibitor of p38α and p38β MAPK SB202190 (InvivoGene, USA) and inhibitor of EGFR kinases BIBX 1382 (Santa Cruz Biotechnology, Inc., U.S.) were dissolved in DMSO to obtain a stock solution at 50 mM. Epidermal growth factor (EGF) at a concentration of 100 ng ml<sup>-1</sup> was used as positive control in the EGFR/ERK signaling pathway as described [40]. Confluent monolayer of Caco-2 cells were incubated for 1 h with 50 µM BIBX 1382, 5 µM SB202190 or 30 min with 50 µM Bay11-7082 and subsequently stimulated with NPs, EGF or left unstimulated. After treatment for indicated time, cells were washed twice with cold PBS and processed as described above. Results of the treated cells are presented as fold change to untreated controls.

Data analysis

Results are presented as means ± standard error (SEM). Treated samples are presented as fold change to untreated controls. Statistical analysis was carried out using GraphPad Prism 4 software (GraphPad Software, Inc., U.S.) and comparisons of the means were performed by ANOVA followed by Tukey’s multiple comparison test. Differences were considered to be statistically significant at p<0.05.

Results and discussion

Nanosized TiO<sub>2</sub> particles and their impacts on in vivo and in vitro systems are currently studied intensively in biomedical research. There are different effects described on cellular level in various cell types. TiO<sub>2</sub> NPs show an impact on oxidative stress, inflammation or apoptosis [5], but the precise cellular mechanisms are still unknown. Several studies discuss a possible activation of toll-like receptors (TLR) [14,29] or suggest an endocytic uptake [15-18] since NPs have been detected intracellular [19-21]. Moreover, our recent findings have shown that cellular response to TiO<sub>2</sub> NPs in Caco-2 cells are dependent on the activation of epidermal growth factor receptor (EGFR), mediated by endocytosis-related structures [13]. Activation of EGFR initiates the induction of downstream signaling pathways, including ERK, JNK and p38 MAPK pathways [41,42]. The present study attempted to provide an insight of the signaling pathway responsible for the NP-induced inflammatory response.

TiO<sub>2</sub> NPs activate ERK1/2 kinases

ERK is part of the Ras/Raf/MEK/ERK signal transduction cascade, which is activated following stimulation by various extracellular factors besides EGF like insulin, other growth factors, osmotic stress, cytokines or trans membrane G-protein coupled receptors [43]. To investigate the role of ERK in the NP-induced inflammatory response, p-ERK expression was determined by western blot analyses and immunocytochemistry. As shown in Figure 1 expression of p-ERK1/2 in Caco-2 cells was induced after treatment with 10 nm TiO<sub>2</sub> NPs compared to untreated control at any time point (Figure 1A to F). Western blot analyses revealed exposure to 10 nm TiO<sub>2</sub> induce a transient activation of p-ERK1/2 (Figure 2A). Levels of p-ERK1/2 consequently increased in a time dependent manner until 60 min after NPs exposure and is significantly induced at 60 min by 10.2±3.1 compared to untreated control cells (Figure 2B). Activation of ERK1/2 faded 90 min after NPs exposure. It was shown EGF treatment increase

![Figure 1. Immunocytochemical staining of p-ERK1/2 in Caco-2 cells exposed to TiO<sub>2</sub> particles. Caco-2 cells were stimulated with 10 nm TiO<sub>2</sub> (concentration of 40 µg cm<sup>-2</sup> of the cell growth surface) for A – 0 min = untreated control, B – 15 min, C – 30 min, D – 45 min, E – 60 min, F – 90 min. Scale bar corresponds to 50 µm.](image)

![Figure 2. TiO<sub>2</sub> NPs induced activation of p-ERK1/2. Caco-2 cells were stimulated with 10 nm TiO<sub>2</sub> (concentration of 40 µg cm<sup>-2</sup> of the cell growth surface) for 15, 30, 45, 60 and 90 min. A – Phosphorylated ERK1/2 was evaluated by western blot analyses. B – Samples are presented as fold change to unstimulated sample = 0 min. Expression of p-ERK1/2 was normalized to total protein expression measured by densitometry. Shown are representative western blots of four independent experiments. Data presented the mean ± SEM. *p<0.05 significantly different to untreated control, One-way ANOVA followed by Tukey’s multiple comparisons test.](image)
the levels of p-ERK1/2 peaking at 2, 5 and 10 min [44]. Therefore the observed induction of ERK1/2 by NPs is slightly slower than with EGF. If the NP-induced ERK1/2 activation resulted from an activation of EGFR or another mechanism is not known. To go more into detail in this issue we further used inhibitors which intervene the ERK and NF-κB pathways. 

**Activation of ERK1/2 is dependent on EGFR**

To analyses signal transduction of the NP-induced inflammatory response, we used three different inhibitors after stimulation with 10 nm TiO$_2$ and EGF. In our recent studies we have shown that NP-induced inflammatory response was dependent on EGFR, NF-κB and p38 MAPK activation [13].

It is known activation of EGFR leads to the phosphorylation of ERK1/2 [41]. As shown by western blot analysis p-ERK1/2 was induced 30 min after NPs and EGF stimulation by factor 2.5 ± 0.4 and 4.2 ± 0.9 compared to untreated control cells (Figure 3A). Densitometric analysis of western blots revealed that treatment with BIBX1382 (EGFR inhibitor) lead to a decreased p-ERK1/2 by 68 % in NP-treated cells and by 83 % in EGF-treated cells compared to the stimulated specimens without inhibitor treatment (Figure 3B). These results shown that NP-induced activation of ERK1/2 is dependent on activation of EGFR. Study with ultrafine carbon black particles support our observations, which shown a transactivation of EGFR and further stimulation of ERK in human bronchial epithelial cells [45].

As published earlier, the NP-induced inflammatory response can be inhibited by BAY11-7082 [13]. Using the same inhibitor at identical concentration, which inhibited the phosphorylation of IκB-α, we shown that p-ERK1/2 is elevated in comparison to untreated cells. Inactuation of IκB-α phosphorylation by BAY11-7082 resulted in a significant increase of p-ERK1/2 in NP2- and EGF-treated specimens by factor 5.7 ± 2.3 and 5.5 ± 1.0, respectively (Figure 3A and 3B). Thus manipulation of the NF-κB pathway confound ERK signaling through a possible feedback mechanism. Different studies already demonstrated interactions between NF-κB and ERK signaling pathway [46-48]. Having shown p38 MAPK is also involved in NP-induced inflammatory response [13], we analyze whether p38 MAPK is therefore not required for the NP-induced activation of ERK1/2 (Figure 3A and 3B). Activation of the ERK-related gene expression was further investigated.

**TiO$_2$ NPs induced binding of ELK1**

The best-studied nuclear target of phosphorylated ERK is the transcription factor ELK1 [28] Stimulation with 10 nm TiO$_2$ increased the binding of ELK1 to ELK1-specific biotin-labeled oligos up to 45 min after TiO$_2$ exposure (Figure 4A) and declined 60 min after NPs treatment. Densitometric analyses revealed a 1.8 ± 0.5-fold increase of the binding complex compared to untreated control. This time course and amount is typical for activated ELK1 [49].

**NP-induced activation of EGFR/ERK/ELK1 signaling pathway is related to the expression of CCL2 and CXCL3**

It has been shown that activation of ERK1/2 induce the expression of CCL2 and CXCL3 mRNA [50]. Expression analysis revealed an increase by factor 11.0 ± 2.6 and 12.6 ± 5.3 3 h after NPs exposure of CCL2 and CXCL3 mRNA, respectively (Figure 5A and B). Pre-incubation with EGFR kinase inhibitor BIBX 1382 decreased the NP-induced expression by 77 % and by 70 % of CCL2 and CXCL3 mRNA. 6 h after NPs treatment mRNA expression of CCL2 and CXCL3 was induced by 4.8 ± 0.4-fold and by 3.3 ± 0.5-fold, respectively. Treatment with BIBX 1382 resulted in a 54 % and 58 % reduction of NP-induced expression of these genes. The results demonstrate that NP-induced expression of ERK target genes is dependent on the activation of
Krüger K (2015) Titanium dioxide nanoparticles induced activation of extracellular signal-regulated kinases signaling pathway in human colonic epithelial Caco-2 cells is mediated by epidermal growth factor receptor

EGFR. It was shown that the expression of CXCL3 and CCL2 mRNA was increased after different inflammatory stimuli and was part of an inflammatory response, mediated by EGFR [51,52]. EGFR-dependent ERK1/2 activation and downstream signaling shown regulatory effects on cellular transformation, intestinal cell migration and wound healing [50,53-55]. Moreover, Unfried et al. demonstrated that carbon NPs induce proliferation via ERK1/2 signaling in lung epithelial cells [56]. This activation was dependent on EGFR. If the TiO$_2$ NP-induced activation of these pathways in Caco-2 cells promote cell migration and transformation remains unknown. Further experiments are needed to clarify this.

Conclusion

We demonstrated that exposure to 10 nm TiO$_2$ NPs induced the activation of ERK1/2 and the expression of ERK1/2 target genes Chemokine (C-C motif) ligand 2 (CCL2) and Chemokine (C-X-C motif) ligand 3 (CXCL3). This cellular response to TiO$_2$ NPs is dependent on the activation EGFR. Furthermore, TiO$_2$ NPs induce the activation of the transcription factor ELK1 and thus suggest an EGFR/ERK/ELK1 signaling pathway. IκB-α was shown to interact in the NP-induced ERK1/2 signaling cascade as treatment with inhibitor BAY11-2616 (concentration of 40 µg cm$^{-2}$ of the cell growth surface) for 15, 30, 45 and 60 min. ELK1 binding was measured by EMSA and shown as binding complex of ELK1 and ELK1-specific biotin-labeled oligos. For competition reaction (comp.) 1000-fold molar excess of unlabeled oligos were used. B – Binding capacity was quantified by densitometry and treated samples are presented as fold change to untreated control. Shown are representative EMSA of three independent experiments. Data presented the mean ± SEM.
