Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

ABSTRACT

Veno-Venous Extracorporeal Membrane Oxygenation (VV-ECMO) is a rescue treatment for severe acute respiratory failure refractory to conventional ventilation. We examined the alterations of sublingual microcirculation in patients with SARS-CoV-2 during VV-ECMO treatment and assessed the relationship between microvascular parameters and ventilation, hemodynamics, and laboratory tests.

Nine patients were included in the study and the following microcirculatory parameters were estimated: TVD 16.81 (14.46–18.6) mm/mm²; PVD 15.3 (14.09–17.96) mm/mm²; PPV 94.85% (93.82%–97.79%); MFI 2.5 (2.5–2.92); HI 0.4 (0.18–0.4). TVD and PVD were inversely related to D-dimer levels (rho = −0.667, p = 0.05 and rho = −0.733, p = 0.025 respectively), aspartate aminotransferase (AST) (rho = −0.886, p = 0.019 and rho = −0.886, p = 0.019 respectively) and alanine aminotransferase (ALT) (rho = −0.829, p = 0.042 and rho = −0.829, p = 0.042 respectively).

Our results showed an altered sublingual microcirculation in patients receiving VV-ECMO for severe SARS-CoV-2 and suggest a potential contribution of endothelia dysfunction to determine microvascular alteration.

1. Introduction

Veno-Venous Extracorporeal Membrane Oxygenation (VV-ECMO) is a rescue treatment for severe cases of acute respiratory failure refractory to conventional mechanical ventilation, neuromuscular blockade, and prone positioning (Sen et al., 2016). During the current pandemic outbreak, many patients with severe acute respiratory syndrome due to novel Coronavirus (SARS-CoV-2), unresponsive to first line therapies, underwent VV-ECMO (Pravda et al., 2020). Multiple evidences suggest that the assessment of sublingual microcirculation may have a role to guide clinical decisions during ECMO treatment (Yeh et al., 2018). Monitoring of sublingual microcirculation provides clinically relevant information representative of microcirculatory alterations of other organ beds (Guven et al., 2020). We recently reported the presence of microcirculatory alterations in patients with SARS-CoV-2 (Damiani et al., 2020). Thus, the aim of this study was to describe the alterations of sublingual microcirculation in patients with SARS-CoV-2 treated with VV-ECMO and to assess relationship between microvascular parameters and ventilation, hemodynamics, and laboratory tests.

2. Materials and methods

A retrospective data collection has been performed including patients with SARS-CoV-2 admitted to Intensive Care Unit at Ospedali Riuniti of Ancona (Italy) between February 2020 and April 2020 receiving VV-ECMO support for severe respiratory failure unresponsive to conventional mechanical ventilation and pronation. The study has been approved by Ethical Committee of Regione Marche (record ID: 2020 121/6152).

We retrieved information of patients that received assessment of sublingual microcirculation as routine clinical practice. Sublingual microvascular videos were recorded using the Cytocam camera. The Cytocam is a third generation handheld videomicroscope that enables the non-invasive, real-time, in vivo visualization of the microcirculation. Three videos from different sublingual areas were recorded with...
adequate contrast and focus and without pressure artefacts. The videos were analyzed offline with dedicated software (Automated Vascular Analysis 3.2, Microvision Medical, Amsterdam, NL) to obtain parameters of vessel density (total vessel density [TVD], perfused vessel density [PVD]) and blood flow quality (microvascular flow index [MFI], percentage of perfused vessels [PPV], and flow heterogeneity index [HI]), as described elsewhere (Scorcella et al., 2018). Only vessels with a diameter less than 20 μm were considered.

Data distribution was assessed using the Kolmogorov-Smirnov test. Data were reported as mean and standard deviation (SD) or median and interquartile range (IQR) as appropriate. The Pearson or Spearman correlation has been used to assessed relationship between microcirculation and other clinical parameters. Further studies are needed to clarify the relationship between microcirculation and other clinical parameters.

### 5. Conclusion

In our report considering patients with SARS-CoV-2 undergoing VV-ECMO, we found altered density and flow microvascular parameters and a relationship between capillary density and D-dimer level, suggesting a potential role of endothelial disfunction to determine microvascular alteration. Further studies are needed to clarify the relationship between microcirculation and other clinical parameters.
