**Abstract**

While renal cell carcinoma frequently metastasizes to the lung, solitary pleural metastasis without lung involvement is extremely rare. A 69-year-old man was admitted to our hospital with a solitary pleural metastasis 6 years after surgery for renal cell carcinoma. Needle biopsy was performed, and the tumor was diagnosed as a metastasis of renal cell carcinoma. The pleural tumor was surgically resected. The patient received interferon-α as postoperative therapy. He has been alive for 9 years without recurrence. Only 11 cases of solitary pleural metastasis have been reported thus far, and of these, 7 involved a large amount of pleural effusion resulting in a poor prognosis. This is the first reported case of solitary pleural metastasis from renal cell carcinoma, which was curatively resected, as indicated by long-term survival.

**Background**

Renal cell carcinoma (RCC) accounts for approximately 2% of all cancers, and nearly 50% of all RCC patients will eventually present with metastatic disease, requiring individualized treatment decisions. Patients with untreated metastatic disease have a 5-year survival rate of 0% to 18% [1]. A notable feature of RCC is its tendency to result in lung metastases, which were found in 55% of cases in an autopsy-based study [2]. Pleural metastasis is comparatively rarer than lung metastasis. Most pleural metastases are associated with metastatic lesions of the lung. Solitary pleural metastasis without lung metastasis is extremely rare. Herein, we report successful treatment by resection in a patient with a solitary pleural metastasis evidently derived from a previously removed RCC.

**Case presentation**

A 69-year-old man underwent a left nephrectomy for stage III 3aN0M0 RCC of clear cell type in our hospital. A total of 300 units per day of interferon-alpha (IFN-α) was administered for 1 year as postoperative chemotherapy. While the patient had not reported any specific complaints at 6 years post operation, chest CT revealed a 25 × 15 mm irregularly shaped tumor located at the anterior chest wall, directly behind the third left rib (Figure 1). Fine-needle aspiration biopsy of the tumor was performed, and histopathological examination suggested that it was an RCC metastasis. Further examination of the abdominal CT and bone scintigraphy were performed to detect additional metastases. No lesions were detected in addition to the pleural metastasis.

The tumor was surgically resected in conjunction with partial resection of the third left rib and left lung. Macroscopically, the resected tumor revealed to be a 2.0 × 1.3 cm yellowish tumor. Microscopically, the lesion consisted of tumor cells growing in an alveolar pattern, separated by stroma, and endowed with prominent sinusoid-like vessels. These tumor cells had abundant clear cytoplasm and uniform, ovoid hyperchromatic nuclei. These histological features were similar to those of the previously resected RCC lesion (Figure 2). The tumor was diagnosed as being

compatible with metastatic RCC of the pleura. The postoperative course was uneventful.

IFN-α was administered for 1 year as postoperative therapy. The patient has been alive for 7 years without recurrence of the carcinoma.

Discussion and conclusions
Metastasis to the lungs or mediastinum may already be present in more than one third of patients with RCC at the time of diagnosis [3]. Although RCC commonly metastasizes to the lung, pleural metastasis is rare. Saitoh et al. [4] have investigated 1,451 autopsy cases of RCC. Of these, 979 cases (76%) had lung metastases, and 154 cases (12%) had pleural metastases; there were no cases of solitary pleural metastases. Kutty et al. [3] reported 25 thoracic metastases of RCC, including 7 cases of pleural metastasis, but none of these 7 cases showed solitary pleural metastasis. According to those reports, RCC spread to parietal pleurae appears to be extremely rare.

Including the case reported in this study, 14 cases of solitary pleural metastasis from RCC have been reported [5–17] (Table 1). Of these, 1 case was not reported precisely, and 7 showed a large volume of pleural effusion at the time of diagnosis. Panaurothoracotomy was performed on 1 patient whose cancer had recurred after surgery. The other 7 patients received chemotherapy. Cases with pleural effusion had a poor prognosis. From a literature search in PubMed and Japanese Centra Revuo Medica databases, we found that the present case is the first reported case of solitary localized pleural metastasis of RCC without pleural effusion and long-term survival after resection.

To date, there is no effective chemotherapy against RCC except interferon therapy; therefore, surgical resection is preferable for localized metastasis thereof. Takashi et al. [18] reported 21 cases of surgical resection of metastatic lesions from RCC. In that report, patients with complete resection of metastasized lesions showed favorable prognoses.

Since the metastatic lesion in our case was solitary and small, surgical resection was performed. Furthermore, the metastatic lesion was detected before the patient complained of any symptoms. By the time symptoms are evident to the patient, the extent of disease is likely to be very advanced (growth of lesion and pleural effusion) and thus incurable. Curative treatment in patients with malignant pleural effusion is quite difficult. Routine CT examination proved very useful in finding the pleural metastatic lesion at the localized stage in this case study. In the future, CT may also prove useful for the detection of lung metastases. Routine monitoring for potential chest metastases by CT and other methods should also be considered, in the context of ‘rescue’ of patients with a solitary detectable metastasis.

Consent
Witten informed consent was obtained from the patient for the publication of this case report and any accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal.
Microscopic findings of primary and metastatic pleural tumors. The lesion comprised tumor cells with abundant clear cytoplasm and small round nuclei with atypia in both primary tumor and metastatic tumor at the pleura (hematoxylin and eosin stain). (A) Primary lesion of the kidney (low magnification). (B) Primary lesion of the kidney (high magnification). (C) Resected tumor with rib and lung. (D) Histological specimen by magnifying glass. (E) Metastatic pleural tumor (low magnification). (F) Metastatic pleural tumor (high magnification).

Table 1: Reported cases of solitary metastasis to the pleura from renal cell carcinoma

Authors’ contributions
MK, the first author of this manuscript, performed this operation and followed the patient’s progress at our hospital as an outpatient and wrote this manuscript. YY presented this case at a conference in Japanese with some discussions. His presentation is the main source of this manuscript. SN investigated this case pathologically. MK discussed the case with KY, who was the attending doctor at our hospital’s inpatient ward, and discussed the content of this manuscript. TO was the head of our department and also assisted this operation. All authors read and approved the final manuscript.
