Abstract The paper deals with the spectroscopic properties of Li₂O -ZnO-B₂O₃ glass containing different concentrations of MoO₃ (ranging from 1 to 5 mol %) were prepared by melt quenching. Spectroscopic (infrared, optical absorption spectra and ESR) properties of these glasses have been carried out. The Optical absorption Spectrum contains one broad absorption band at 681 nm, this attributed to the excitation of Mo⁵⁺ (4d¹) ion. ESR studies reveal Molybdenum ions are expected to exist mainly in the Mo⁶⁺ state in the glass network. As the concentration of MoO₃ is increased, especially beyond 5.0 mol %, the colour of the glasses increased, that indicating the reduction of molybdenum ions from the Mo⁶⁺ state to the Mo⁵⁺ state. ESR, IR and Optical absorption spectra of paramagnetic ion in the above glasses reveal that the site symmetry of the transition metal ion is elongated octahedral.

Keywords MoO₃, ESR Spectra, IR Spectra, Optical Properties

1. Introduction

The glasses containing transition metal ions (TMI) came into prominence because of their notable spectroscopic properties and their suitability for fiber optic communications, luminescent solar energy concentrators (LSC)¹. Among the conventional glasses, borate glasses have been known to be excellent host materials for transition metal oxides because of their glass forming nature compare to other conventional glass systems. Borate glasses are used as wave-guides, electro-optic switches, electro-optic modulators, magneto-optic materials, solid-state laser materials and non-linear optical parametric converters ²-⁴. In addition, they are often used as dielectric and insulating materials and it is known that borate glass constitute a good shield against IR radiation ⁵. In general B₂O₃ glasses contain the greatest amount of boric oxide that shows a minimum expansion, a property which is of great importance in obtaining thermal durability. It also decreases the tendency for glass to devitrify or crystallize. B₂O₃ is a basic glass former because of its higher bond strength, lower cation size and smaller heat of fusion. Among the three modifier oxides, viz., ZnO, PbO, CaO; ZnO having covalent character ⁶, is expected to shorten the time taken for solidification of glasses during the quenching process. ZnO, reduces the coefficient of thermal expansion, thus making possible the production of glass products of high resistance to thermal shock. Molybdenum ions in the glasses have been the subject of many investigations due to their catalytic properties. The ions of molybdenum inculcate high activity and selectivity in a series of oxidation reactions of practical importance in the glass matrices ⁷, ⁸. Mo−O bond in molybdenum hexavalent oxide is identified as covalent. The Mo ion exists at least in two stable valence states viz., Mo(V) and Mo(VI) in the glass network. Earlier ESR studies on the glasses containing molybdenum ions have identified the presence of octahedrally coordinated Mo(V) ions along with distorted octahedrons approaching tetragons ⁹, ¹⁰. These ions act both as network formers as well as network modifiers depending upon their concentration and nature of the host network. The Mo⁶⁺ ions are expected to participate in the glass network with tetrahedral MoO₄ structural units and may alternate with BO₄ tetrahedral units. Most of the studies available on MoO₃ containing glasses are on the understanding of their structure by spectroscopic investigations ¹¹, ¹² and ionic conductivity studies ¹³.

In the present contribution the influence of MoO₃ in varying concentrations, on resonance and absorption properties of lithium-zinc-borate glasses are described in some detail. Optical band gaps for both direct and indirect transitions and Urbach energies were calculated and those glasses were also characterized by EPR and IR studies.

2. Experimental
The glasses of the system 10Li2O-(10-x) ZnO-80B2O3: xMoO3 (x= 0, 1, 2, 3, 4 and 5 mol %) have been prepared by adopting the melt quenching technique. The raw materials used were analytical pure ZnO, Li2CO3, H3BO3. Appropriate amounts of weighed chemicals were grounded thoroughly in a mortar to produce homogeneous mixture. This homogenized mixture was then placed in porcelain crucibles and melted in an electrical furnace in air at 870°C-920°C for half an hour until a bubble free liquid was formed. The melt was then quenched to room temperature in air by pouring it on to a Brass slab. The glasses thus obtained were transparent and in color. Details of experimental procedure and calculations are similar to the earlier work 14.

3. Results and Discussion

3.1. Absorption Spectra

The Optical absorption spectra of the Li2O-ZnO-B2O3: MoO3 glasses recorded at room temperature in the wavelength range 400nm-1400nm. The Optical absorption spectrum of molybdenum doped lithium zinc borate glass (with x=3 mol %) is shown in the Fig. 1. The absorption edge observed is observed to shift towards higher wavelength side. The spectrum of MoO3 free glasses does not exhibit any absorption band. But small amount of molybdenum is added to glasses matrix shows a broad optical absorption band at about 681 nm 15. The intensity of this band was observed to increase gradually as the concentration of MoO3 increased. From an extrapolation of the linear portion of the curves of Fig. 2(a), 2(b), 2(c), gives direct, indirect band and Urbach energy gap so determined are presented in Table I. The values of direct and indirect band gap energies, decreases from M1 to M5.

3.2. EPR Spectra

The ESR spectra of the glasses recorded at room temperature exhibit signals consisting of a central line surrounded by smaller satellites at about \( g_\parallel = 1.9286 \) and \( g_\perp = 1.9486 \) for M3 glass system and is shown in Fig.3. The central line arises from even molybdenum isotopes (I=0) whereas the satellite lines correspond to the hyperfine structure from odd \(^{95}\)Mo and \(^{97}\)Mo (I=5/2) isotopes. The spectrums closely resembles that of the molybdenum ion in most oxide glasses, from the spectral analysis, the spin-Hamiltonian parameters were calculated using the following equation and are presented in the Table II. The EPR spectra are analyzed using spin-Hamiltonian:

\[
H = g_\parallel \beta H_\parallel S_z + g_\perp \beta (H_x S_x + H_y S_y) + A_\parallel S_z I_z + A_\perp (S_x I_x + S_y I_y)
\]  

Here Z is the symmetric axis, \( \beta \) is the Bohr magneton, S and I are the electron and nuclear spin operators, \( H_x, H_y, \) and \( H_z \) are the static magnetic field components, \( g_\parallel \) and \( g_\perp \) are the parallel and perpendicular components of the g tensor and, \( A_\parallel \) and \( A_\perp \) are the parallel and perpendicular components of the hyperfine tensor A. The values of \( A_\parallel \) are calculated using the following equations.

\[
H_\parallel (-3/2) - H_\parallel (+3/2) = 3 A_\parallel
\]

The analysis of ESR spectra of these samples suggest that Mo\(^{5+}\) ions are essentially coordinated in these glass ceramics by five oxygen ligands in a square pyramidal form C\(_{4v}\) symmetry with a Mo = O double bond 16.

| $M_3$      | 1342                              | 1051                                         | 809                                            | 550                                            | 475                 |
| $M_4$      | 1340                              | 1049                                         | 808                                            | 550                                            | 474                 |
| $M_5$      | 1336                              | 1047                                         | 807                                            | 548                                            | 479                 |
3.3. Infrared Spectra

The prominent IR bands shown in Fig. 4 are observed for Li₂O-ZnO-B₂O₃: MoO₃ glasses and these bands are effectively influenced by the molybdenum content in the glasses network. The molybdenum free glasses exhibited in the regions 1300-1450 cm⁻¹, 1100-1200 cm⁻¹. These bands are identified as stretching relaxations of B-O bonds of the trigonal BO₃ units. Broad absorption bands are observed at 1050-900 cm⁻¹ and 800-650 cm⁻¹; these bands are identified due to stretching vibrations of the [BO₃] units. A band at 525 cm⁻¹ is due to Zn-O tetrahedral units and a band due to vibrations of ZnO₄ structural units is located at about 470 cm⁻¹ in the spectra of all the glasses. When molybdenum is added, two new bands attributed to υ₁ and υ₃ vibrational modes of [MoO₄]²⁻ tetrahedral units and [MoO₆]⁶⁻ have also been located at about 810 and 550 cm⁻¹ is observed. The summary of various band position of Li₂O-ZnO-B₂O₃ : MoO₃ is furnished in the Table III.

4. Conclusions

The conclusions drawn from analysis of the results of the various properties of Li₂O–ZnO–B₂O₃ : MoO₃ glasses reported in this study are as follows:

● The Optical absorption Spectra of Li₂O–ZnO–B₂O₃ : MoO₃ glasses exhibits bands associated with transitions at Mo⁵⁺ ions, indicating that the molybdenum ions is in pentavalent state, in addition to tetravalent and hexavalent states respectively in these glass samples.
● The EPR Spectra of these glasses exhibit a signal consisting of a triplet separated by smaller satellites. The signal has been identified as arising from tetragonally distorted octahedral positions of Mo⁵⁺ ions.
● The IR Spectral studies indicate that the molybdenum ions occupy tetrahedral positions in larger concentrations in sample M₅.
