Ephrin-B3 coordinates timed axon targeting and amygdala spinogenesis for innate fear behaviour

Xiao-Na Zhu1,2,3, Xian-Dong Liu2,4, Suya Sun1, Hanyi Zhuang5, Jing-Yu Yang3, Mark Henkemeyer6 & Nan-Jie Xu2,4

Innate emotion response to environmental stimuli is a fundamental brain function that is controlled by specific neural circuits. Dysfunction of early emotional circuits may lead to neurodevelopmental disorders such as autism and schizophrenia. However, how the functional circuits are formed to prime initial emotional behaviours remain elusive. We reveal here using gene-targeted mutations an essential role for ephrin-B3 ligand-like activity in the development of innate fear in the neonatal brain. We further demonstrate that ephrin-B3 controls axon targeting and coordinates spinogenesis and neuronal activity within the amygdala. The morphological and behavioural abnormalities in ephrin-B3 mutant mice are rescued by conditional knock-in of wild-type ephrin-B3 during the critical period when axon targeting and fear responses are initiated. Our results thus define a key axonal molecule that participates in the wiring of amygdala circuits and helps bring about fear emotion during the important adolescence period.
Mammalian evolution has required the successful development of emotional systems to cope with various environmental stimuli. Amygdala serves as the core of the brain emotional system that primes innate defensive reactions and learned fear behaviours. In view of its widespread functional connections with sensory associative areas, the amygdala is regarded as a sensory gateway for integration of a wide array of emotional information. In addition to emotional control, the amygdala participates in psychiatric disorders and, in particular, the socio-emotional impairment. In human patients and animal models of neurodevelopmental disorders, including autism spectrum disorders and schizophrenia, dysfunction of amygdala-associated brain networks has been reported. Determining the precise timing and mechanisms that control nerve wiring to form the amygdala network is crucial to our understanding of the plasticity of neuronal responses, and thus the molecular basis of emotional behaviour.

As the brain develops, there exist critical periods in which specific circuits are susceptible to environmental stimuli that participate in shaping certain types of innate behaviours or neural function. A critical period of nerve wiring involves various brain regions/nuclei that connect to the amygdala, leading to synapse formation and the generation of emotional arousal. We hypothesize that the inter-nucleus wiring is mediated by trans-synaptic interaction of guidance molecules with the following characteristics: (i) timed expression in associated essential nuclei, (ii) involved in synaptic formation/remodelling and (iii) crucial for neurotransmission and plasticity. Among the molecules fulfilling these criteria, ephrin and Eph receptors are involved in sensory integration and cognitive function and transduce bidirectional signals to integrate pre- and post-synaptic development on axon-dendrite/cell contact. Our previous studies revealed essential roles for the transmembrane protein ephrin-B3 (henceforth referred to as eB3), a major member enriched in neurons of the cortex and hippocampus, and in axon pruning, synaptogenesis and synaptic plasticity, during early postnatal development. The time-restricted roles of eB3 suggest its significance in neural circuit formation and initial inter-nucleus coordination necessary for the formation of key neural networks. This is in agreement with recent reports that link ephrin-B-EphB signal deficit to anxiety disorders, autism and mental retardation. However, eB3 plays a role in vivo in regulating emotional brain function remains unknown.

In the present study, we identify an early onset time for initial defensive behaviour, a specific response mediated by the activation of neurons in the amygdala, and demonstrate that synaptic eB3 is required for initial formation of primitive brain emotions. Furthermore, we find that eB3 serves as a major mediator for targeting of hippocampal CA1 axons into the amygdala and plays a trans-nucleus role in timed coordination of spinogenesis. The coordination of axon/synapse development and neuronal function is mediated by axonal eB3 that initiates trans-synaptic signals into amygdala neurons during the critical period in the adolescence brain when innate fears are initially formed. Our findings thus provide a molecular mechanism for how neural circuit assembly is processed and regulated to affect neuronal activity and innate fear behaviour.

Results

eB3 is required for amygdala-mediated fear responses. To identify the initial onset of innate emotional behaviour, we combined a behavioural test with analysis of activated c-Fos expression in the amygdala to study defensive behavioural and neuronal reactions that respond to aversive stimuli. Using either a testing trial with an elevated plus maze (EPM) or an exposing trial to a predator odour TMT (2,5-dihydro-2,4,5-trimethylthiazoline), innate defensive responses can be triggered in juvenile or adult animals. In both behavioural paradigms, defensive responses were elicited specifically by threat stimuli in juvenile mice (Supplementary Figs 1 and 2). In these behavioural trials, a marked increase in number of c-Fos-positive cells was observed in several brain regions involved in sensory integration, the cortex and hippocampus, and in emotional signal processing, habenula nucleus, medio-dorsal thalamic nucleus and ventromedial hypothalamus, during postnatal development (Supplementary Fig. 1c). In particular, c-Fos activation in the basolateral amygdala (BLA) was markedly increased starting from postnatal day 16 (P16; Fig. 1a,b).

Using gene-targeted mice we examined the potential roles for eB3 in BLA neuronal activity and innate behaviours with both behavioural paradigms. The Efnb3 null mutant mice were subjected to EPM, and significant longer exploring time and more entries in the open arm of the maze were clearly observed from P16 until P42, reflecting a defect of innate fear response (Fig. 1c,d, Supplementary Movies 1 and 2). In TMT paradigm, Efnb3 mice showed less avoidance responses compared with wild-type mice (Supplementary Fig. 2, Supplementary Movies 3 and 4). The altered fear responses were also reflected by a reduction in c-Fos-positive BLA neurons in either EPM or TMT paradigm (Fig. 1c,e). Furthermore, c-Fos-positive neurons were reduced in the habenula nucleus, medio-dorsal thalamic nucleus and ventromedial hypothalamus of Efnb3 mice (Supplementary Fig. 1c). As a transmembrane protein, eB3 is capable of transducing bidirectional signals by either serving as ligand to bind and stimulate EphB receptor-expressing cells (forward signalling), or functioning as receptors per se to transduce autonomous reverse signals into the cells it is expressed on (reverse signalling), as demonstrated to be essential for dendritic development of hippocampal CA1 pyramidal neurons. Therefore, to examine whether reverse signalling mediated by the cytoplasmic domain of eB3 is involved in innate behaviour, Efnb3 mice were subjected to EPM and TMT paradigms. These eB3 mutant mice express a truncated ephrin-B-β-gal fusion protein (eB3-β-gal) that retains the extracellular and transmembrane domains to provide ligand-like activity but are unable to transduce reverse signals. Unlike the Efnb3 knockout, Efnb3 mice showed no difference compared with the wild-type littermates in EPM or TMT fear responses (Fig. 1c,d), nor did they show reduction in c-Fos-positive BLA neurons (Fig. 1e). These genetic data indicate that eB3 likely serves a ligand-like role to stimulate forward signalling events needed for trans-nucleus wiring of the amygdala and formation of innate fear responses.

eB3 mediates axon targeting and amygdala spinogenesis. By using in situ hybridization, eB3 transcripts are highly detected in the forebrain, and in particular the level of eB3 in hippocampal CA1 region reaches its peak at P14 (Supplementary Fig. 3a), a time that parallels the onset of initial defensive behaviour. We were then curious about how loss of eB3 caused such behavioural defects in EPM and TMT paradigms. We first examined for morphological abnormalities at P16 in Efnb3 mutant mice that also contain the Thy1-GFP M transgenic line, which visualizes a subset of neurons during the postnatal critical period. We used two-photon images from 400-µm-thick coronal brain sections to identify fluorescent long projecting axons and observed a bundle of downward-projecting fibres starting from the ipsilateral edge of the hippocampus and extending into the amygdala (Fig. 2a). The upper part of the axon bundles look similar between mutant and wild type, exhibiting a thick fasciculated track, indicating that eB3 deletion did not affect the
Figure 1 | eB3 is required for defensive responses and activation of neurons in the amygdala. (a) c-Fos expression (arrowheads indicated yellow cells) in neurons of the amygdala was markedly elicited after an EPM behavioural trial from P9 to P20. Blue: neurotrace to stain BLA cell layer at P9–P20. Scale bar, 100 μm. (b) Quantification of c-Fos-positive cells (percentage of total neurotrace-positive cells) in BLA or lateral amygdala (LA) from P9 to P20 following an EPM or TMT behavioural trial. n = 6 mice for each group. (c) Representative animal track of EPM, and representative images showing the c-Fos-positive cells in amygdala of Efnb3+/+ , Efnb3−/− and Efnb3lacZ/lacZ mutant mice following EPM trial at P16. Scale bars, 100 μm. (d) Efnb3−/−, but not Efnb3lacZ/lacZ, mutant mice showed a longer time and a higher probability of open-arm entry than Efnb3+/+ at P16, P20 and P42. The experiments were triplicated independently. n values of mice used are indicated above group bars. *P < 0.05; **P < 0.01; ***P < 0.001, one-way ANOVA. (e) Quantification of the cells with c-Fos expression at Efnb3+/+, Efnb3−/− and Efnb3lacZ/lacZ mutant in BLA, LA, CA1 and DG following an EPM or TMT trial. n values of mice are indicated above group bars. *P < 0.05; ***P < 0.001, one-way ANOVA. Overall axon growth/guidance and projection from the hippocampus. However, in Efnb3−/− mutant we found that in the more distal region of the bundle, the axon terminals enter the amygdala, the nerve fibres were loosely packed and not well-wired with BLA neurons in contrast to the tightly and neatly fasciculated bundles observed in the wild-type and Efnb3lacZ/lacZ mice (Fig. 2a,b). The abnormalities were not likely attributable to the changes in axon growth as mentioned above or neurogenesis (Supplementary Fig. 4). This result indicates that the extracellular segment rather than the intracellular domain of eB3 is required for normal fasciculation and targeting of these hippocampal neuron axon projections into the BLA. We thus dissected the amygdala tissue out and examined it for changes in synaptic molecules in the BLA of wild-type and Efnb3−/− mutant mice at P16. We observed an obvious decrease in the pre-synaptic marker synapsin and an adaptive increase of post-synaptic calcium channels GluN1 (Fig. 2c). Altogether, these results suggest that the loss of eB3 expression results in abnormal targeting of hippocampal axons extending into BLA, and that this affects normal pre- and post-synaptic integration.

Notably, eB3 is not expressed in BLA neurons as indicated by X-gal staining in Efnb3lacZ mice (Supplementary Fig. 3), in which the eB3-β-gal fusion protein is expressed in the correct temporal, spatial and subcellular pattern as the endogenous wild-type protein and provides for a high signal-to-noise ratio reporter. We thus hypothesized that eB3 expressed on hippocampal CA1 axons that target the amygdala may affect BLA neurons by binding with one of its receptors EphB2, which is expressed in BLA28, to control targeting of pre-synaptic axon terminals and initiate synapse formation. EphB2−/− mice resembled Efnb3−/−-innate fear behaviours in EPM paradigm (Supplementary Fig. 5a), supporting a trans-nucleus eB3-EphB2 interaction. As the combined parameters of spine density and spine size/shape determine the total excitatory input from these pre-synaptic terminals10-42, we analysed spine morphogenesis of BLA neurons by using confocal images of brain sections from Efnb3−/− mutant mice to examine the possible trans-nucleus effect of eB3. According to the algorithm for classification of spine shape adapted in our previous study43, we analysed the density of various spine groups in Thy1-GFP-labelled BLA neurons, and observed a significant reduction in the fraction of mature mushroom spines but no obvious change in the fraction of thin or stubby spines in Efnb3−/− mice at P16 when compared with wild-type or Efnb3lacZ/lacZ mice (Fig. 2d,e). The decrease in mushroom spines in Efnb3−/− mice persisted at P20 but reached a normal level at P42 (Supplementary Fig. 6).
**Figure 2 | eB3 is required for axon targeting and spinogenesis in amygdala neurons.**

(a) Comparison of axonal bundles projected into amygdala between Efnb3+/+, Efnb3−/− and Efnb3lacZ/lacZ mice with Thy1-GFP M background. The vertical dotted line crossing the axon bundles is 1,000-µm long from top to bottom and 300-µm distance from left lateral edge of BLA. Scale bars, 100 µm. (b) Quantification of the total peak number of axonal signals with GFP crossing the dotted line and fasciculated axonal bundles (indicated with red square brackets). n values of brain slices from 6 to 7 mice per group are indicated above each group bar. ***P < 0.001, one-way ANOVA. (c) Protein expression of synaptic molecules in amygdala of Efnb3+/+ and Efnb3−/− mice. Synapsin1 expression is downregulated, while GluN1 (NMDA receptor) is upregulated in Efnb3−/− mice. (d) Efnb3−/− but not Efnb3lacZ/lacZ mutant mice showed delayed spine maturation and reduced c-Fos activation in BLA neurons at P16. Red is c-Fos immunofluorescence and green is the small number of random BLA neurons that are Thy1-GFP M positive and outline post-synaptic spine structures. Scale bars, 40 µm, 25 µm and 5 µm for the upper, middle and lower panels, respectively. (e) Quantification of density for various types of spines in WT, Efnb3−/− and Efnb3lacZ/lacZ mutant at P16. n values of neurons from 5 to 6 mice per group are indicated above each group bar. *P < 0.05, one-way ANOVA. (f) Correlation of the c-Fos immunofluorescence (IF) and the density of mushroom spines in c-Fos-positive neurons (left panel) in Efnb3+/+, Efnb3−/− and Efnb3lacZ/lacZ mutant at P16 following EPM trial. n = 15 neurons from 6 mice for Efnb3+/+, r² = 0.75; n = 22 neurons from 8 mice for Efnb3−/−, r² = 0.24; n = 10 neurons from 5 mice for Efnb3lacZ/lacZ, r² = 0.63. All the samples were from triplicated experiments.
Consistently, EphB2−/− mice also showed decreased mushroom spines in BLA neuron dendrites at P16 but with normal hippocampus projected axon bundles towards BLA (Supplementary Fig. 5b,c). To investigate the functional consequence of abnormal spine morphology, we analysed for c-Fos immunofluorescence in GFP-labelled amygdala neurons and plotted the c-Fos level of these neurons versus the density of mushroom spines. We found that the density of mushroom spines was actually correlated with the c-Fos level in wild-type ($r^2 = 0.75$, $P < 0.0001$) and Ephb3−/− mice ($r^2 = 0.63$, $P < 0.0001$), while this correlation was completely abolished in Ephb3−/− mice ($r^2 = 0.24$, $P = 0.02$; Fig. 2f). These results suggest that eB3 is required for the timely maturation of mushroom spines and robust neuronal activation (that is, c-Fos) in the amygdala at the early postnatal period.

**eB3 rescue initiates timed axon targeting and fear responses.**

To further verify the temporal and spatial specificity of eB3 for defensive responses, we utilized a conditional knock-in strategy to induce eB3 re-expression at an endogenous level in the Ephb3−/− mice. The Ephb3−/− mutant line we used above was generated by inserting a loxP-flanked PGK-neo cassette into the intron between the fourth and the fifth exons of Ephb3, which results in a protein-null allele27. This insertion allows us to conditionally remove the floxed neo cassette by adding Cre recombinase and thereby rescue wild-type eB3 expression. To address the question about brain specificity for the role of eB3, we first crossed the Ephb3−/− mutants with a CamKII-Cre transgene44, a forebrain excitatory neuron-specific Cre for the PGK-neo cassette deletion, and a loxP-flanked Stop-ttdTomato reporter (CamKII-cre−; tdtomato+; Ephb3−/−) to visualize the distribution and efficiency of CamKII-Cre recombination (Fig. 3a). Our data showed that CamKII-Cre recombination increased rapidly in the hippocampus CA1 area, where eB3 is highly expressed, during P12 to P20 (Fig. 3b). In the EPM trial at P16 we found that the defect in behaviour and c-Fos activation observed in Ephb3−/− mutants was restored back to normal in CamKII-cre−; tdtomato+; Ephb3−/− mice (Fig. 3c,d). These data rule out the possibility that the changes in the defensive responses observed in the Ephb3−/− mice are the result of a possible defect due to loss of eB3 earlier in brain development before P12, and suggest that the role of eB3 is during the critical postnatal stages when fear behaviour initiates.

As adjoining nuclei, the hippocampus and amygdala are functionally associated with each other in the adult brain8,45–48, though clinical evidence of patients with focal lesions to these two systems indicate that they can also operate independently7,8,49. We validated the anatomical and functional connection between the two regions in juvenile mice by using both slice electrophysiology (Supplementary Fig. 7) and dye tracing (Supplementary Fig. 8). We recorded fEPSP signals in BLA following hippocampal electrode stimuli in the ventral hippocampal CA1 region, and observed constant fEPSP in slices from P16 wild-type mice that were significantly reduced in amplitude in the Ephb3−/− mice (Supplementary Fig. 7). Through dye tracing from the hippocampal CA1 region, labelled axons were detected in BLA as early as P12 (Supplementary Fig. 8).

The role of eB3 was further examined using an injected AAV2-NLS-Cre-induced rescue strategy in the Ephb3−/− mice. We injected AAV2-td-Tomato control or AAV2-NLS-Cre virus into the CA1 region of the intermediate or ventral hippocampus in newborn tdTomato+; Ephb3−/− mice to trace axon projections (Supplementary Fig. 9a), and found that td-Tomato fluorescence-expressing axons appeared in the region of Thy1-GFP-labelled axon bundles, indicating the anatomical origin of these fibres (Supplementary Fig. 9b). The projected axon terminals from td-Tomato-labelled CA1 neurons were observed to form synapses with dendritic spines of BLA neurons (Supplementary Fig. 9c). At P16 these mice were subjected to behavioural tests, and a significant restoration in innate defensive response, amygdala c-Fos activation and mushroom spines was observed in AAV2-NLS-Cre-injected td-Tomato+; Ephb3−/− mice, which was comparable to the normal level (Supplementary Fig. 9d–f). The ability of CA1-injected AAV2-NLS-Cre to rescue the Ephb3−/− phenotypes is consistent with the idea that hippocampal eB3 is required for trans-nuclei wiring into the BLA.

We next addressed whether the role of eB3 in trans-nucleus regulation was time dependent. We utilized Ephb3−/− mice containing a ubiquitous CAGG-CreERT2M transgene and the loxP-flanked Stop-td-Tomato reporter (CAGG-cre−; Ephb3−/−), and treated them with tamoxifen on the first day of postnatal period P12–P16 or P38–P42 to activate Cre recombinase and rescue eB3 expression (Fig. 4a,b and Supplementary Fig. 10). After tamoxifen treatment at P12, the defective defensive behaviour observed in Ephb3−/− was restored to a normal level, comparable to that of wild-type littermates, in the end of the eB3 rescuing time P16 (Fig. 4c). However, tamoxifen treatment at P38 failed to rescue the behaviour, suggesting a time-restricted role for eB3 in generation of fear responses. We then asked whether the time-restricted modulation by eB3 involves time-dependent axon targeting and connection. Following tamoxifen treatment, we observed loosely packed and tangled axon bundles adjoining the amygdala at P16 or P42 in CAGG-cre−; Ephb3−/− control mice that showed the behavioural defects in innate fear responses (Fig. 4d,e). However, the abnormal axonal morphology for Thy1-GFP-expressed axon bundles was restored in tamoxifen-treated CAGG-cre−; Ephb3−/− mutant mice of P12–16 rescuing period, which maintained normal appearance at P42 (Supplementary Fig. 11), but not in the mice of P38–P42 rescuing period (Fig. 4d,e). These data indicate time-restricted roles for eB3 in axon targeting and neuronal connection to control defensive behaviour.

**Timed trans-nucleus coordination for functional spinogenesis.**

Finally, to examine if the timely eB3 rescue is sufficient to restore the spinogenesis and defensive neuronal reaction in BLA, we measured BLA c-Fos cell number and further detected the c-Fos immunofluorescence level of Thy1-GFP cells in tamoxifen-treated CAGG-cre−; Ephb3−/− and CAGG-cre−; Ephb3−/− control mice (Fig. 5a). We found that the defect in BLA c-Fos activation observed in eB3 null was restored in tamoxifen-treated CAGG-cre−; Ephb3−/− mutant mice at P16 but not at P42 (Fig. 5b). We further detected the morphology of BLA neurons in these mice after tamoxifen treatment at P16, and plotted their immunofluorescence level versus the density of mushroom spines to quantify for correlation of spinogenesis and neuronal activation. These data showed that the correlation of c-Fos immunofluorescence to mushroom spine density in BLA neurons was restored in CAGG-cre−; Ephb3−/− mice ($\tau^2 = 0.65$, $P < 0.0001$) to a level comparable to that of wild-type mice (Fig. 5c,d). This is in agreement with the restoration of defensive behaviour.

In summary, our experimental data reveal that deletion of eB3 leads to significant defects in innate fear behaviour (Fig. 1), which is associated with a disruption in neuronal connection with amygdala neurons (Fig. 2). The results are consistent with the idea that eB3 stimulates forward signalling to guide axon targeting for trans-nucleus modulation and thereby coordinates spinogenesis and neuronal activation in BLA (Figs 1 and 2). Moreover, we used a conditional knock-in strategy to rescue
endogenous eB3 to investigate the spatial and temporal relationship of eB3-mediated axonal targeting and the behavioural defects (Figs 3 and 4). The defensive neuronal response and innate fear behaviour is directly related to the time-restricted CA1 axon targeting and BLA neuron spinogenesis, while eB3 rescue at a later period failed to restore BLA neuronal activation and defensive behaviour (Fig. 5). Taken together, our study indicates that eB3 participates in axon targeting and trans-nucleus integration associated with spinogenesis of BLA neurons in a time-dependent fashion that couples neuronal activation to aversive cues, initiating defensive neuronal responses for innate fear.

Discussion

In the present study, we uncovered biological mechanisms regulating innate emotional responses. We found that eB3 deletion leads to a significant defect in innate fear behaviour, which is associated with a disruption in connections of amygdala neurons. Our data may help resolve the controversy in the field of emotions about whether there are innate emotion circuits in the brain, and strongly support the presumption that innate emotions are of a ‘natural kind’ and are hard-wired into brain circuits by evolution. We further revealed that eB3 functions to integrate pre- and post-synaptic structures and thereby coordinates axon targeting, spinogenesis and neuronal reactions in the amygdala. This study indicates a new function for eB3 in vivo, which is in contrast with the previous studies on roles of ephrin-B/EphB-mediated bidirectional signalling for axon guidance and synaptic plasticity within the brain.

Interestingly, our results show that only the ligand-like activity of eB3 is required for axon targeting, spinogenesis and innate fear (Figs 1 and 2). This rules out the repulsive effects of eB3 reverse signalling for stereotyped axon pruning, which is mediated by its intercellular domain interacting with cytoskeletal regulators, and suggests an adhesive effect of eB3 mediated by its extracellular domain for consolidation of neuronal connection on axon–dendrite contact.

Our study also revealed a specific developmental period for trans-nucleus modulation on spinogenesis of amygdala neurons and their defensive reaction, which in the mouse occurs between P12 and P16. This period is critical for the spine-reaction coupling in the developing brain (Fig. 5). In addition to previous studies on the essential role of critical developmental periods in numerous brain functions, our results add evidence that the timed spinogenesis in BLA neurons coupled to aversive response serves as a key neural mechanism accounting for critical period-based innate defensive behaviours.

The brain elicits innate defensive reactions by integrating sensory inputs with critical brain nuclei that are involved in the initiation and modulation of amygdala-mediated emotional responses. The expression of eB3 is observed mainly in the hippocampus but not in the amygdala, raising the question of how eB3 in these areas initiates molecular signals to modulate amygdala through wired trans-nucleus synapses. Mechanistically, on binding of eB3 extracellular domain to the pre-synaptic axon terminals, EphB receptor tyrosine kinases in the post-synaptic responsive spines could become clustered and activated (see the model in Fig. 5e). Phosphorylated EphB receptors can regulate...
GluN1 receptor-dependent influx of calcium, leading to synaptic function-related gene expression28,53,57,58, which eventually facilitates spine morphogenesis and hence neuronal reactions to aversive cues.

In contrast to previous studies on the adult hippocampus that imply functions for exchanging messages as a specific engram via existing contextual pathways to participate in sophisticated learned emotions4,9,12, the trans-nucleus role of eB3 during the existing contextual pathways to participate in sophisticated functions for exchanging messages as a specific engram via aversive cues.

In view of the genetic and protein linkage of ephrin-B-EphB/EphA signal deficit to anxiety disorders28, autism29, William’s syndrome63 and Angelman’s syndrome31, our further analysis clarifies the mechanisms by which the structural and functional circuit assembly to the amygdala are coordinated in the developing brain and leads to an increased understanding of the molecular basis for emotion-associated brain functions and disorders.

Methods

Mice. Efnb3−/− (ref. 27), Efnb3loxP−/− (ref. 38), EphB8−/− (ref. 52), CaMKII-Cre+ (ref. 44) and CAGG-Cre+ (ref. 64) knock-out and knock-in mice and genotyping methods have been described previously. The Efnb3−/− mutation was
Neurons from 7 mice for defensive responses in BLA neurons. The mushroom spinogenesis and defensive neuronal activity are disrupted in formation and EphB receptor kinase activation consolidate the trans-nucleus neuronal connection that is required for spinogenesis and threat stimulated responses.

Pre-synaptic eB3 guides hippocampal axon targeting to connect with amygdala neurons through binding with EphB receptors. The eB3-EphB tetramer triplicated experiments. c-Fos activation in BLA neurons at P16 following tamoxifen administration at P12 increased significantly compared with tamoxifen administration at P12 in indicated above group bars. **P<0.01, one-way ANOVA. eB3 rescue increased the density of mushroom spines in BLA neurons at P16 following tamoxifen administration at P12 in CAGG-Cre+/–; Efnb3–/– mice. n values of neurons from 5 to 6 mice each group are indicated above each group bar. *P<0.05, one-way ANOVA.

(d) Correlation of c-Fos immunofluorescence (IF) and the density of mushroom spines in c-Fos-positive neurons (left panel) in Efnb3+/+, CAGG-cre–/– and CAGG-cre+/– mice after EPM trial at P16. n = 18 neurons from 6 mice for Efnb3+/+, r² = 0.74; n = 19 neurons from 7 mice for CAGG-Cre–/–; Efnb3–/–, r² = 0.23; n = 17 neurons from 6 mice for CAGG-Cre–/–; Efnb3–/–, r² = 0.65. All the samples were from triplicated experiments. (e) Model of timed pre- and post-synaptic coordination for inter-nucleus neuronal connection for defensive neuronal responses. Pre-synaptic eB3 guides hippocampal axon targeting to connect with amygdala neurons through binding with EphB receptors. The eB3-EphB tetramer formation and EphB receptor kinase activation consolidate the trans-nucleus neuronal connection that is required for spinogenesis and threat stimulated defensive responses in BLA neurons. The mushroom spinogenesis and defensive neuronal activity are disrupted in Efnb3–/– mice.

Figure 5 | Time-specific eB3 rescues synaptogenesis and defensive responses in Efnb3–/– mutant. (a) eB3 rescue improved spine maturation and c-Fos activation in BLA neurons at P16 following tamoxifen administration at P12 in CAGG-Cre+/–; Efnb3–/– mice. Scale bars, 40 µm, 25 µm and 5 µm for the upper, middle and lower panels, respectively. (b) The percentage of c-Fos-positive cells in BLA in CAGG-Cre+/–; Efnb3–/– mice after an EPM trial at P16 increased significantly compared with CAGG-Cre–/–; Efnb3–/– mice following tamoxifen treatment at P12 but not that at P38. n values of mice used are indicated above group bars. **P<0.01, one-way ANOVA. (c) eB3 rescue increased the density of mushroom spines in BLA neurons at P16 following tamoxifen administration at P12 in CAGG-Cre+/–; Efnb3–/– mice. n values of neurons from 5 to 6 mice each group are indicated above each group bar. *P<0.05, one-way ANOVA. (d) Correlation of c-Fos immunofluorescence (IF) and the density of mushroom spines in c-Fos-positive neurons (left panel) in Efnb3+/+, CAGG-cre–/– and CAGG-cre+/– mice after EPM trial at P16. n = 18 neurons from 6 mice for Efnb3+/+, r² = 0.74; n = 19 neurons from 7 mice for CAGG-Cre–/–; Efnb3–/–, r² = 0.23; n = 17 neurons from 6 mice for CAGG-Cre–/–; Efnb3–/–, r² = 0.65. All the samples were from triplicated experiments. (e) Model of timed pre- and post-synaptic coordination for inter-nucleus neuronal connection for defensive neuronal responses. Pre-synaptic eB3 guides hippocampal axon targeting to connect with amygdala neurons through binding with EphB receptors. The mushroom spinogenesis and defensive neuronal activity are disrupted in Efnb3–/– mice.

generated by inserting a loxP-flanked PGK-neo cassette into the intron between the fourth and the fifth exons of Efnb3 that results in a protein-null allele27. The primary targeted allele of Efnb3–/– homozygote was crossed with CamKII-Cre line/CAGG-Cre mouse line and a tdTomato reporter mouse line. Endogenous level of eB3 in the initial Efnb3–/– mutant was restored on Cre expression that induced excision of the loxP-flanked PGK-neo cassette. All the mice were crossed with the Thy1-GFP M transgenic mouse line. Consecutive backcrosses to the CD1 strain were performed to move the mutations to CD1 background. Half male and half female of the mice from P9 to P42 were used in the experiments as indicated in the ‘Results’ section. All experiments involving mice were carried out in accordance with the US National Institutes of Health Guide for the Care and Use of Animals under an Institutional Animal Care and Use Committee approved protocol and Association for Assessment and Accreditation of Laboratory Animal Care approved Facility at the Shanghai Jiao Tong University School of Medicine.
Elevated plus maze. All tests were conducted according to a previous study.65 Mice were habituated to handling and transport from the colony room to the behavior chambers before behavioral tests were begun. The visual ability of mice was checked with a light-induced locomotory behaviour in a transparent testing chamber, and the time to first body turn away from a bright flashlight (2 Hz) at one end was recorded.45 Mice were given 1 h to habituate after transport to the behavioural room before any tests were conducted. All apparatuses and testing chambers were cleaned with 75% ethyl alcohol wipes between animals.

The EPM apparatus was made of dark grey plastic and consisted of two open arms (30 × 7 × 0.25 cm) opposed to two enclosed arms (30 × 7 × 15 cm) elevated 60 cm from the floor. Animals were placed in the central area of the apparatus with their head facing an enclosed arm (test duration: 5 min). The test was performed in a sound-attenuated and temperature-controlled (23 ± 1°C) room illuminated by one 40-W fluorescent bulb placed 3 m above the apparatus. Digitized video recordings (30 frames per second) with EthoVision software (Noldus Information Technology, Leesburg, VA) were used for behavioural analysis. The average velocity and total arm entries were considered as an index of locomotor activity, whereas the percentage of time spent in open arms and the percentage of open arm entries were used as innate fear indexes.

Innate olfactory exposure trial. An odour-TMT test was adapted to evaluate innate fear, in which the front door of the exposure PVC tube (10 × 2 cm) was made out of paraffin with a cavity in the centre to enable mice to smell specific odours. Mice were initially habituated to the testing tube for 2 min, and were then exposed to 20 µl of the odour (either water, isoamyl acetate, sesame oil or TMT (100 mg/ml)). The odour-TMT test was performed under 'blinded' conditions. For quantitative analysis for the shape of linear dependence between c-Fos immunofluorescence and the percentage of the slices with indicated height in BLA, each double-labelled neuron (Thy1-GFP and c-Fos) located in BLA was counted as a single data point. Acquisition of the images as well as morphometric quantification was performed under 'blinded' conditions.

In vitro electrophysiology. Brain coronal slices were prepared from Efnb3+/+ and Efnb3−/− mice at P16. Brains were dissected quickly and chilled in ice-cold artificial cerebrospinal fluid maintaining (in mM): 119 NaCl, 2.5 KCl, 2.5 CaCl2, 1.3 MgCl2, 26 NaHCO3, 1 NaH2PO4 with 95% O2/5% CO2. Coronal brain slices from the Efnb3+/+ and Efnb3−/− mice were prepared with a vibratome. After recovery, slices were placed in the recording chamber and continuously perfused with the artificial cerebrospinal fluid. Recording pipettes were pulled on a Flaming Brown P-80 PC Micropipette puller (Sutter Instrument, Novato, CA) filled with 3.5 M NaCl for extracellular recordings to achieve a resistance of 2–4 MΩ. Data were collected with an AxoClamp 2B recording amplifier (Molecular Devices, Union City, CA). FLA-01 Bessel filter unit (Cygnus Technologies, Delaware Water Gap, PA) and pCLAMP9.0 software (Molecular Devices). Slices were stimulated using a bipolar concentric electrode (FFH, Bowdoin, ME) that was placed in ventral hippocampal CA1 pyramidal cells layer and connected with a stimulator (AMPI, Jerusalem, Israel). After a 15 min equilibration period, field potentials were recorded in the amygda region. Each slice culture was recorded for 20 min intervals (2 min on, 2 min off) over a 20 min time period, for a total of 10 min of recorded activity.

Statistical analysis. The results are presented as mean ± s.e.m. Statistical differences were determined by Student’s t-test for two-group comparisons or ANOVA followed by Dunnett’s test for multiple comparisons among more than two groups.
