Background: SWI/SNF-related, matrix-associated, actin-dependent regulator of chromatin subfamily C member 1 (SMARCC1) protein is a potential tumor suppressor in various cancers. However, its role in prostate cancer (PCa) remains controversial. The aim of this study was to determine the biological function of SMARCC1 in PCa and explore the underlying regulatory mechanisms.

Methods: The expression of SMARCC1 was validated in PCa tissues by immunohistochemistry. Meanwhile, function experiments were used to evaluate the regulatory role on cell proliferation and metastasis in PCa cells with SMARCC1 depletion both in vitro and in vivo. The expression levels of relevant proteins were detected by Western blotting.

Results: Our finding showed that SMARCC1 was significantly downregulated in prostate adenocarcinoma, with a higher Gleason score (GS) than that in low GS. The decreased expression of SMARCC1 was significantly correlated with a higher GS and poor prognosis. Additionally, we found that silencing of SMARCC1 dramatically accelerated cell proliferation by promoting cell cycle progression and enhancing cell migration by inducing epithelial mesenchymal transition (EMT). Furthermore, depletion of SMARCC1 facilitated PCa xenograft growth and lung metastasis in murine models. Mechanistically, the loss of SMARCC1 activated the PI3K/AKT signaling pathway in PCa cells.

Conclusion: SMARCC1 suppresses PCa cell proliferation and metastasis via the PI3K/AKT signaling pathway and is a novel therapeutic target.

Keywords: SMARCC1, prostate cancer, proliferation, epithelial-mesenchymal-transition, PI3K/AKT pathway
INTRODUCTION

Prostate cancer (PCA) is a common malignancy afflicting elderly males, with over 1.6 million men diagnosed every year (Pernar et al., 2018; Siegel et al., 2021). In America, the morbidity rate of PCAs has ranked first in all cancer-related deaths (Siegel et al., 2021). Globally, it is estimated that 366,000 men die of PCA annually, making it the fifth most common cause of cancer-related deaths worldwide (Pernar et al., 2018; Siegel et al., 2021). Multiple mutations in several key epigenetic factors, including Rb1 and BRCA, drive the progression of PCAs to aggressive phenotype at terminal stage, characterized by limited survival, revealing an important role of epigenetic dysregulation on PCA progression (Crea et al., 2011; Liu, 2016; Chan et al., 2018; Sheahan and Ellis, 2018; Oh et al., 2019; Wu et al., 2019; Ge et al., 2020; Liang et al., 2020). However, the specific function and profound mechanisms of various epigenetic factors involved in PCA progression are still uncertain. Thus, it is extremely urgent and worthwhile to further explore the role and mechanisms of epigenetic regulators in PCA progression.

The SWI/SNF-related, matrix-associated, actin-dependent regulator of chromatin subfamily C member 1 (SMARCC1) is one of the core subunits of the SWI/SNF complex involved in epigenetic regulation on genome transcription (Reisman et al., 2009; Shain and Pollack, 2013; Hohmann and Vakoc, 2014; Alver et al., 2017; Lu and Allis, 2017; Savas and Skardasi, 2018). It is regarded as a tumor suppressor in several cancers, including renal, colon, and pancreatic carcinoma (Andersen et al., 2009; Iwagami et al., 2013; Wang et al., 2021). However, its role in PCAs remains ambiguous and controversial. Previous studies have shown that SMARCC1 is upregulated in PCAs tissue and may promote the initiation and progression in PCAs via the transactivating androgen receptor (Hong et al., 2005; Heeboll et al., 2008), whereas a retrospective study on patients with local PCAs indicated that SMARCC1 positive staining in the prostate biopsy samples correlated with prolonged survival, which is indicative of a tumor-suppressive role in PCAs (Hansen et al., 2011). These discrepancies may be partly attributed to different cancer models and expression systems.

In this study, we aimed to explore the role of SMARCC1 in the proliferation and metastasis of PCAs by using a series of in vitro functional assays and in vivo mouse model due to lack of conclusive research on the mechanism of SMARCC1 during PCA progression. Moreover, the potential mechanism by which SMARCC1 mediates the development and progression of PCAs was also investigated.

MATERIALS AND METHODS

Prostate Cancer Tissues

Tumor and matched benign prostatic hyperplasia tissue samples were collected from 100 PCAs patients who received radical prostatectomy for prostate cancer at Nanfang Hospital, Southern Medical University (Guangzhou, China). The PCAs patients were enrolled in our research project according to the following standards: (1) the patients were diagnosed with PCAs before surgery, in accordance with biopsy pathological diagnosis, (2) post-operation pathological examination confirmed the diagnosis of PCAs, and (3) the patients were informed and consented to the collection of specimens. Meanwhile, some PCAs patients were excluded from our research cohort due to the following criteria: (1) patients with other malignant diseases or a second primary tumor, (2) PCAs patients who received preoperative androgen deprivation therapy, chemotherapy, or radiotherapy before surgery, and (3) HIV- or syphilis-positive patients. The relevant clinicopathological data of the patients was also obtained. All patients signed the informed consent, and sample collection was approved by the ethical protocols of the Ethics Committee of Nanfang Hospital, Southern Medical University.

Immunohistochemistry

The paraffin sections were dewaxed in xylene, rehydrated through an ethanol gradient, and washed in phosphate buffer saline (PBS). After boiling in 10 mM citrate buffer (pH 6) for 10 min for antigen retrieval, the sections were immersed in 3% H2O2 for 10 min to inhibit endogenous peroxidase. The sections were then blocked with 1% goat serum and incubated overnight at 4°C for primary antibodies against SMARCC1 (1:800; Abcam, cat. ab126180, United States), E-Cadherin (1:100; CST, cat. 24E10, United States), Claudin1 (1:100; CST, cat. 13255T, United States), MMP2 (1:50; HuaBio, cat. ER40806, China), P504S (1:100; Proteintech, cat. 15918-1-AP, China), and Ki67 (1:100; Bioss, cat. BA1063, China) at 4°C. After washing thrice with PBS, the sections were then probed with the secondary antibody for 1 h and rinsed three times with PBS. The DAB Kit (Bioss, cat. BP0770, China) was used for immunostaining, and the nucleus was counterstained with hematoxylin. The sections were then dehydrated through an ethanol gradient and sealed with neutral balsam. The stained sections were observed under a light microscope (BX53, Olympus, Japan) fitted with a digital camera (DP72, Olympus, Japan). The in situ SMARCC1 expression level was analyzed independently by two pathologists blinded to the patients’ clinical information. The staining intensity was scored as negative (0), weak (1), medium (2), or strong (3), and the percentage of positively stained area was scored as 0 (0%), 1 (1–25%), 2 (26–50%), 3 (51–75%), and 4 (76–100%). The total staining score was calculated by multiplying the intensity and positivity scores, and the samples were graded as low (0–5), medium (6–8), and high (9–12) expression accordingly. In addition, low staining intensity in tissue was classified as

Abbreviations: PCA, prostate cancer; SMARCC1, SWI/SNF-related, matrix-associated, actin-dependent regulator of chromatin subfamily C member 1; BPH, benign prostatic hyperplasia; GS, Gleason score; SWI/SNF complex, Switch/sucrose non-fermentable complex; H&E staining, hematoxylin and eosin staining; PBS, phosphate buffer solution; PI3K/AKT, phosphatidylinositol 3 kinase/protein kinase B; PBS-tween solution; PSB, phosphate buffer solution; Rb1, retinoblastoma-associated protein 1; BRCA, breast cancer susceptibility gene; ATPase, adenosine triphosphatase.
negative, while both medium and high staining intensity were classified as positive.

**Bioinformatics Analyses**
The disease-free survival data was extracted from the Gene Expression Profiling Interactive Analysis (GEPIA) database¹ and analyzed using R. The cutoff was set as 30% high vs. 70% low.

**Cell Culture**
RWPE-1, LNCAP, C4-2, PC3, 22RV1, and DU145 cell lines were obtained from the Cell Bank of Typical Culture Preservation Committee of the Chinese Academy of Sciences (Shanghai, China). The RWPE-1 cells were cultured in primary keratinocyte culture medium (iCell Bioscience Inc., cat. PriMed-iCell-010, China), and the other cell lines were cultured in RPMI 1640 (Gibco, cat. 11875-093, United States) supplemented with 10% fetal bovine serum (FBS; Gibco, cat. 10270-106, United States) and 1% penicillin–streptomycin solution (Gibco, 15140-122, United States) at 37°C under 5% CO₂. As per experimental requirements, the cells were treated with 20 ng/ml LY294002 (Macklin, cat. HY-10108, China) in dimethyl sulfoxide for 24 h (Bao et al., 2015).

**SMARCC1 Knockdown**
The cells were seeded in six-well plates at a density of 0.5 × 10⁶ cells/well and transfected 24 h later with SMARCC1 siRNA using Lipofectamine 3000 (Invitrogen, United States). The cells were harvested 48 h after transfection, and SMARCC1 mRNA and protein levels were analyzed by quantitative real-time polymerase chain reaction (qRT-PCR) and western blotting. The lentivirus vector containing the SMARCC1 shRNA was synthesized by Vigene Biosciences Inc. (China). Briefly, 0.5 × 10⁶ cells were plated in six-well plates and infected 24 h later with the virus at a multiplicity of infection (MOI) of 30 in serum-free medium. Fresh complete medium containing 2 μg/ml puromycin was added 48 h after infection, and the cells were cultured for 4 days. The sh-SMARCC1 cells with stable knockdown were detected by qRT-PCR and western blotting. siRNA targeted to SMARCC1: 5′-CCUCACAAGACGUAAGATT-3′ 5′-UCUUCAGCGUCUUGAGGTT-3′ was synthesized in GenePharma Co., Ltd (Suzhou, CHINA) and sh RNA contained SMARCC1 (Bao et al., 2015).

**RNA Extraction and qRT-PCR**
RNA was extracted using Trizol reagent (Invitrogen, cat. 15596018, United States) and reverse-transcribed to cDNA using PrimeScript RT Master Mix Kit (Takara, cat. RR036A, Japan) according to the manufacturer’s instructions. The cDNA was amplified with the PrimeScript™ RT-PCR Kit (Takara, cat. DRR015A, Japan) on Applied Biosystems™ 7500 fast Dx real-time PCR cycler (Thermofisher, United States) according to the manufacturer’s protocol. GAPDH was used as the internal control, and relative expression levels were calculated by the 2−ΔΔCT method. Primer sequence was obtained from website primerbank (https://pga.mgh.harvard.edu/primerbank/) and shown as following: SMARCC1 (Forward sequence: 5′-AGCTGTTTATCGACGGAAGGA-3′; Reverse sequence: 5′-GACATCCGATGAACATCTTCTT-3′); GAPDH (Forward sequence: 5′-GGAGCGAGATCCCTCCAAAT-3′; Reverse sequence: 5′-GGCTGTTGTCATACTTCTCATGG-3′).

**Protein Extraction and Western Blotting**
The suitably treated cells were homogenized in radio-immunoprecipitation assay (RIPA) buffer supplemented with phenylmethylsulfonyl fluoride (KGP250, KeyGen BioTECH, Nanjing, China) at the ratio of 1,000:1, along with protease inhibitor (Mecklin, cat. P885281, China) and phosphatase inhibitor (FDbio, cat. FD7186, China), each at 100:1 ratio. The cells were lysed by ultrasonication for 20 min and centrifuged at 12,000 rpm for 5 min at 4°C. The nuclear and cytoplasmatic proteins were fractionated using the nucleus extraction kit (Pythonbio, cat. AAPR285, Guangzhou, China). Briefly, 1 × 10⁵ cells were lysed using a specific buffer at 4°C for 20 min and centrifuged for 5 min. The cytoplasmatic fraction was removed, and the nuclear fraction was washed thrice with PBS. Protein was extracted from both fractions using RIPA buffer as described above. The respective supernatants were aspirated, mixed with × 5 loading buffer (FDbio, cat. FD0006, China) at a ratio of 1:4, and denatured by boiling. An equal amount of protein per sample was separated by 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis and transferred to polyvinylidene fluoride membrane (Millpore, cat. MB0323, United States). After blocking with 10% milk or bovine serum (for phosphorylated proteins), the membranes were incubated overnight with primary antibodies specific for SMARCC1 (1:500; CST, cat. D7F83, United States), Cyclin D1 (1:500; CST, cat. 92G2, United States), Cyclin E1 (1:500; CST, cat. HE12, United States), CDK6 (1:500; CST, cat. DSC83, United States), p21 (1:500; CST, cat. D21D1, United States), p27 (CST, cat. D96C12, United States), E-Cadherin (1:500; CST, cat. 24E10/4A2, United States), N-Cadherin (1:500; CST, cat. D411H, United States), Vimentin (1:500; CST, cat. D21H3, United States), β-catenin (1:500; CST, cat. D10A8, United States), Snail (1:500; CST, cat. C15D3, United States), Slug (1:500; CST, cat. C19G7, United States), Zeb1 (1:500; CST, cat. D80D3, United States), Zeb2 (1:500; ABC clone, cat. A5705, CHINA), Akt (1:500; CST, cat. C67E7, United States), p-AktSer473 (1:500; CST, cat. D9E, United States), p-AktThr308 (1:500; CST, cat. D25E6, United States), GAPDH (1:1,000; Proteintech, cat. 104941-AP, China; CST, cat. D465R, United States), and H3 (1:500; Bioss, cat. bs-0349R, China) at 4°C. Total and cytoplasmatic proteins were normalized to GAPDH, and nuclear protein was normalized to histone H3. PVDF membranes were washed with PBS-tween solution (PBST) and incubated with horseradish peroxidase-conjugated secondary antibody for 1 h. After washing thrice with PBS, the positive bands were detected by FDbio-Dura enhanced chemiluminescence kit (FDbio, cat. FD8020, China).

**Cell Viability Assay**
The cells were seeded in 96-well plates at a density of 1,000 cells/well in triplicates, and viability was measured using the Cell Counting Kit 8 (Dojindo, cat. CK04, Japan) according to the manufacturer’s instructions. The absorption at

Bold values illustrate statistical significance.

450 nm was detected using Microplate Reader Synergy Neo2 (Biotek, United States).

**Colony Formation Assay**

The cells were seeded in six-well plates at a density of \( 3 \times 10^3 \) cells/well in complete medium and cultured for 12–14 days till colonies were visible. The colonies were fixed with methanol and stained using the Wright–Giemsa kit (Baso, cat. BA4017, China). Colonies harboring >50 cells were counted under a microscope.

**Flow Cytometry Assay**

The cell cycle distribution was analyzed using a specific detection kit (KeyGENE BioTECH, cat. KGA512, Nanjing, China). Briefly, the suitably treated cells were harvested and fixed in 75% ethanol for 48 h. After washing with PBS, the cells were incubated with ribonuclease at 37°C for 30 min to remove intracellular RNA. The DNA was stained with propidium iodide (PI), and cells were acquired in the FACS Calibur flow cytometer (Bioscience, United States) to measure the DNA content.

**EDU Assay**

The cells were incubated with EDU solution (EDU assay kit, cat. C10310-1, RiboBio, China) diluted 1:1,000 in complete medium for 2 h. After washing thrice with PBS, the cells were fixed with 4% paraformaldehyde for 10 min and neutralized by 2 mg/ml glycine. The cells were then permeabilized with 0.5% Triton and incubated with the kit reaction agent for 30 min. After washing thrice with 0.5% Triton and once with methanol, the cells were counterstained with Hoechst 33342 (diluted 1:1,000 with ddH2O) for 10 min to stain the nucleus and washed thrice with PBS. The EDU-positive cells were counted under an inverted microscope (Olympus, cat. 1X71, Japan) fitted with DP72 camera (Olympus, Japan).

**Immunofluorescence Assay**

The cells were seeded in a 24-well plate at a density of \( 0.2 \times 10^6 \) cells/well and fixed with 4% paraformaldehyde for 10 min following 24 h of incubation. After neutralizing with 2 mg/ml glycine, the fixed cells were permeabilized with 0.5% Triton for
10 min and washed thrice with PBS. The cells were then blocked with 10% BSA for 1 h and incubated with primary antibodies against E-Cadherin (1:100; CST, cat. 24E10, United States), N-Cadherin (1:100; CST, cat. D411H, United States), Vimentin (1:100; CST, cat. D21H3, United States), β-catenin (1:200; CST, cat. D10A8, United States), and p-AktSer473 (1:200; CST, cat. D9E, United States) at 37°C for 2 h. After washing thrice with PBST for 5 min, the cells were incubated with the secondary antibody at 37°C for 1 h. The stained cells were washed thrice with PBST and observed under an inverted microscope (Olympus, cat. 1X71, Japan) fitted with DP72 camera (Olympus, Japan).

**Wound Healing Assay**

The cells were seeded in a six-well plate at a density of $0.8 \times 10^6$ cells/well and cultured for 48 h till 90% confluent. The monolayer was scratched longitudinally with a 10-µl pipette tip, and the debris was removed by washing thrice with PBS. Fresh serum-free medium was added, and the wound region was photographed at 0, 12, and 24 h after scratching under an inverted microscope (Olympus, cat. 1X71, Japan) with DP72 camera (Olympus, Japan). The extent of wound healing was measured using Image J (NIH, United States).

**Transwell Assay**

The cells were seeded in the upper chambers of 24-well Transwell inserts (Corning, cat. 3422, United States) at a density of $1 \times 10^5$ cells/well in serum-free medium, and the lower chambers were filled with complete medium supplemented with 20% FBS. After culturing for 48 h, the unmigrated cells on the upper surface of the membranes were swabbed...

RESULTS

SMARCC1 Is Downregulated in PCa Tissues With GS More Than 7 and Correlates With Poor Prognosis

Compared with that in matched non-tumorous tissues of BPH, in situ SMARCC1 expression in PCa tissue was slightly upregulated without statistical significance (Figure 1A and Table 1). In PCa cases with GS > 7, in situ SMARCC1 expression was significantly downregulated (Figure 1A and Table 2). Consistent with this, the GEPIA data showed that the high expression of SMARCC1 positively correlates with prolonged disease-free survival in PCa patients (Figure 1B). Thus, the loss of SMARCC1 portends poor prognosis and disease progression in PCa. Moreover, endogenous expression of SMARCC1 in PCa cell lines was validated using western blotting assay and was further knocked down using transient transfection of siRNA or lentivirus vector containing short hairpin RNA (Figures 1C–E).

SMARCC1 Silencing Accelerates the Metastasis of PCa Cells by Inducing EMT

SMARCC1 silencing significantly increased the viability of PCa cells as well as the number of colonies formed in vitro (Figures 2A,B). Loss of SMARCC1 upregulated cyclinD1/E1 and downregulated the cyclin-dependent kinase inhibitors (CKIs) p21 and p27, which indicated accelerated cell cycle transition (Figure 2C). Consistent with this, EDU incorporation and PI staining assays showed that SMARCC1 knockdown increased the percentage of cells entering S and G2 phases and decreased that of cells remaining in G1 phase (Figures 2D,E). In conclusion, SMARCC1 loss in PCa cells accelerated cell cycle progression and increased their proliferation by downregulating CKIs and activating cyclin D1/E1.

SMARCC1 Silencing Accelerates the Metastasis of PCa Cells by Inducing EMT

Transwell and wound healing assays showed that loss of SMARCC1 significantly increased the migration of PCa cells in vitro (Figures 3A,B). Consistent with this, SMARCC1 knockdown markedly increased the expression of mesenchymal markers, including vimentin and N-cadherin, and decreased that of E-cadherin (Figures 3C,D). In addition, EMT-related transcription factors, including Slug, Snail, and Zeb1, were also

Statistical Analysis

All statistical analyses were performed using GraphPad 7.0 (GraphPad Software Inc., United States) or SPSS 22.0 (IBM Corp., United States). Chi-square test or Fisher’s exact test was used to determine the correlations between the in situ protein abundance and the clinicopathological factors in PCa tissues. Numerical data were expressed as means ± standard error of mean. Differences between variables were confirmed by two-tailed Student’s t-test or one-way analysis of variance (ANOVA) for continuous variable groups. When ANOVA was significant, post-hoc testing of differences between groups was carried out using the least significant difference test. Survival curves were plotted using Kaplan–Meier’s method and compared by the log-rank test. A P-value < 0.05 was considered statistically significant.
upregulated in the SMARCC1-knockdown cells (Figure 3D). In conclusion, SMARCC1 loss promoted the EMT of PCa cells, thereby inducing migration and metastasis.

Knockdown of SMARCC1 Promotes the Growth and Metastasis of Human PCa Cells in vivo

To validate the potential impact of SMARCC1 depletion on PCa cell proliferation in vivo, PC-3/sh-SMARCC1 cells and PC-3/sh-Ctrl as well as 22Rv1/sh-SMARCC1 cells and 22Rv1/sh-Ctl cells were injected subcutaneously in nude mice. Tumors in mice implanted with sh-SMARCC1 cells grew faster than control cells. SMARCC1 knockdown cells exhibited significantly larger tumor volume and weight than control cells (Figure 4A). H&E staining showed the histopathological features of the tumor tissues. The positive rate of proliferation mark, Ki-67, was dramatically higher in xenografts with sh-SMARCC1 cells by IHC staining (Figure 4A). These results provide evidence that SMARCC1 may be a remarkable determinant for PCa cell growth. As for tumor metastasis in vivo, a tail vein xenograft model was generated. The tumor presence was validated by histological examination. The results demonstrated that mice injected with 22Rv1/sh-SMARCC1 shRNA cells produced more lung colonization compared to those with that of the control cells (Figures 4B,C). As shown in Figure 4D, P540S was stained to confirm the neoplasms’ histologic type and origin of lung colonization. Moreover, we also found that the SMARCC1-knockdown pulmonary tumor nodules showed significantly higher levels of the matrix metalloproteinase (MMP2) and low levels of epithelial markers including E-Cadherin and Claudin 1 (Figure 4E).

Loss of SMARCC1 Activates the PI3K/AKT Pathway in PCa Cells

SMARCC1 knockdown activated the PI3K/AKT pathway in PCa cells, as indicated by the elevated phosphorylation of Akt at ser-473 and thr-308 (Figures 5A,B). Activation of the PI3K/AKT pathway stabilizes β-catenin and promotes its nuclear translocation, wherein it regulates the transcription of target genes. Loss of SMARCC1 significantly increased the accumulation of β-catenin in the nuclear fraction of PCa cells (Figures 5C,D). Furthermore, the PI3K/AKT pathway blockade with the specific inhibitor LY294002 reversed the pro-proliferative and pro-metastatic effects of SMARCC1 knockdown (Figure 6) without completely altering the expression levels of EMT and proliferation-related factors. This indicates that the PI3K/AKT pathway may partly mediate the pro-oncogenic effect induced by SMARCC1 knockdown in PCa, and other pathways and mechanisms may also be involved (Figure 7).

DISCUSSION

High frequent mutations of several key epigenetic factors, including Rb1 and BRCA, have been revealed to induce an aggressive phenotype at the terminal stage of PCa and reflect a promoting effect of epigenetic dysregulation on PCa progression. As one of the core subunits, SMARCC1 belongs to the SWI/SNF complex, which functions as a key epigenetic complex on genome transcription and consists of 12–14 subunits, including adenosine triphosphatase (ATPase), core, and other accessory subunits (Reisman et al., 2009; Shain and Pollack, 2013; Hohmann and Vakoc, 2014; Alver et al., 2017; Lu and Allis, 2017; Savas and Skardasi, 2018; Lei et al., 2019). A high frequency of mutations with function loss in coding genes of the SWI/SNF complex has been identified by whole genome sequencing in various cancers, especially renal carcinoma and melanoma, implying its important role in tumor suppression (Shain and Pollack, 2013; Stachowiak et al., 2020; Tsuda et al., 2021; Wang et al., 2021; Zhou et al., 2021). Mechanistically, the loss of function of the SWI/SNF complex promotes the transcription of genes related to proliferation and dedifferentiation, impairs DNA repairs, and reduces the antagonistic effect on the PRC complex (Nagl et al., 2005; Wilson et al., 2010; Tolstorukov et al., 2013; Alver et al., 2017; Stanton et al., 2017; Aras et al., 2019; Ribeiro-Silva et al., 2019; Hu et al., 2020).
However, the role of the SWI/SNF complex is ambiguous and controversial in PCa (Deocampo et al., 2004; Hong et al., 2005; Link et al., 2005; Heeboll et al., 2008; Hansen et al., 2011; Lee and Roberts, 2013; Prensner et al., 2013). Several studies show that it promotes PCA initiation and progression by transactivating the androgen receptor (Deocampo et al., 2004; Hong et al., 2005; Link et al., 2005), but there are also reports that some subunits function as tumor suppressors (Hansen et al., 2011; Lee and Roberts, 2013; Prensner et al., 2013). For instance, the long non-coding RNA SChLAP1 promoted an aggressive PCA phenotype by antagonizing the SNFS subunit (Lee and Roberts, 2013; Prensner et al., 2013). The effect of SMARCCI in PCa is likewise still ambiguous and controversial. One study demonstrated the upregulation of SMARCCI in PCa tissues relative to benign prostate tissues (Heeboll et al., 2008), whereas a retrospective study found that the positive staining of SMARCCI in PCa tissues correlated with prolonged survival among local PCA patients (Hansen et al., 2011). In this study, we systematically elucidated the expression and role of SMARCCI in PCa. Our findings demonstrated that SMARCCI was significantly downregulated in PCa tissues with GS > 7, and its low expression correlated with shortened disease-free survival. In addition, silencing of SMARCCI in PC-3, 22RV1, and LNCaP cells significantly increased cell proliferation by promoting entry into the S phase of the cell cycle and facilitated cell migration by inducing EMT. The in vivo studies using a murine model showed that SMARCCI knocking down led to the acceleration of tumor growth and lung metastasis. These observations demonstrated the tumor-suppressive role of SMARCCI in PCa.

Infinite proliferation is an important hallmark of tumors (Nagl et al., 2005; Hu et al., 2020). Timing of proliferation depends on the transition speed of cell cycle and is directly associated with the expression of cell cycle-related genes (Nagl et al., 2005; Carrassa, 2013; Hu et al., 2020). Cell cycle transition through different checkpoints is driven by specific cyclins and cyclin-dependent kinases (CDKs) and blocked by CKIs that inhibit cyclins and cyclin–CDK complexes (Nagl et al., 2005; Hu et al., 2020). It has been reported that component loss of the SWI/SNF complex downregulates CKIs and upregulates cyclins at the transcriptional level (Nagl et al., 2005; Hu et al., 2020). Consistent with previous reports, we found that SMARCCI knockdown accelerated cell cycle transition and induced a hyper-proliferative phenotype in PCA cell lines by upregulating G1/S-specific protein cyclin D1/E1 but downregulating cyclin-dependent kinase inhibitors p21 and p27, implying that SMARCCI may be a potential druggable target for cell cycle checkpoint pathway in PCa.

Subunit loss in the SWI/SNF complex induces dedifferentiation phenotype, while EMT results from dedifferentiation in cancer cells (Alver et al., 2017; Wang and Unternaehrer, 2019). Previously, studies have indicated that the subunit loss of the SWI/SNF complex may facilitate the metastasis of tumor cells by inducing EMT in colon and gastric carcinoma (Yan et al., 2014; Wang et al., 2019). EMT is triggered by transcription factors like Snail, Slug, and Zeb1 that repress the epithelial factor E-cadherin and endows the cells with greater metastatic abilities (Yan et al., 2014; Wang and Unternaehrer, 2019; Wang et al., 2019). However, it was uncertain whether the suppression of SMARCCI would induce EMT in PCa. We, therefore, analyzed the key proteins of EMT and found that silencing of SMARCCI resulted in a remarkably increased expression of vimentin and N-cadherin as well as a reduced expression of E-cadherin, which are considered as characteristic features of EMT.

It has been reported that the component loss in the SWI/SNF complex promotes the malignant progression of rhabdomyosarcoma and ovary carcinoma via activation of the PI3K/AKT pathway (Foster et al., 2009; Bitler et al., 2015). In PCa, activation of the PI3K/Akt pathway promotes the nuclear translocation of β-catenin, which triggers the expression of proliferation and EMT-related genes and specifically promotes tumor progression by transactivating androgen receptor and its downstream pathway (Sharma et al., 2002; Hennessy et al., 2005; Carnero, 2010; Noorolyai et al., 2019). However, the specific role of the PI3K/Akt pathway in PCa with SMARCCI loss still needs to be investigated. Previous studies revealed the synergistic effect of the SWI/SNF complex with other epigenetic factors, including histone acetylase and Rb1, on genome transcription (Strobeck et al., 2000; Chatterjee et al., 2018), while SMARCCI functions as a scaffold structure in the SWI/SNF complex to undertake coordination with other epigenetic factors (Chatterjee et al., 2018), even though we observed a significant upregulation of β-catenin in the nuclear fraction of PCa cells with SMARCCI depletion in our study, indicating that the PI3K/AKT pathway mediates the pro-oncogenic effects of SMARCCI loss. However, the PI3K/AKT inhibitor LY294002 only partially reversed these pro-oncogenic effects, which indicates the potential involvement of other epigenetic factors. Taken together, SMARCCI may function as a tumor suppressor in PCa along with other epigenetic factors, which warrant further investigation.

In summary, the downregulation of SMARCCI is correlated with a poor prognosis and an aggressive phenotype of PCa. SMARCCI depletion facilitates PCA cell proliferation by promoting cell cycle progression and enhanced cell migration by EMT. In addition, SMARCCI loss activates the PI3K/Akt signaling pathway, which plays a key role in the progression of PCa. Therefore, SMARCCI may be a promising therapeutic target in PCa, especially for cases with low expression levels (Figure 8).
