Dear Editor,

Persistent hematuria could trigger urinary retention, leading the patient to the emergency department for abdominal pain, decreased urinary output, anemia, and azotemia [1,2]. Conventional bladder clot evacuation requires a three-way catheter with continuous irrigation and aspiration with a syringe or Ellik evacuator [3]. Sometimes a large and well-organized hematoma requires an open cystostomy [1,4]. We want to introduce a combined method using hydrogen peroxide as well as suction technique with an endotracheal catheter to evacuate intravesical clots.

A 75-year-old patient diagnosed with locally advanced prostate cancer and a 65-year-old patient diagnosed with muscle-invasive bladder cancer were seen in the emergency department. Both presented with a history of gross hematuria (more than 100 red blood cells per high-power field [RBC/HPF]) with 5 days and 2 days of evolution, respectively, and acute suprapubic pain accompanied by urinary retention. Ultrasound demonstrated a large intravesical clot in both patients. The patient with prostate cancer had a clot volume of 120 cm³, and the patient with bladder cancer had a clot volume of 50 cm³. We decided to place a three-way catheter to carry out the continuous irrigation of the bladder as well as suction technique with an endotracheal catheter to evacuate intravesical clots.

Figure 1 The placement of the three-way catheter and bladder flushing. (A) Endotracheal suction catheter with the suction vent; (B) Endotracheal suction catheter passing through the cystoscope sheath. (Fig. 1B). We checked that there were no clots left on the bladder at the end of the procedure with a standard cystoscopy and verified the integrity of the bladder. We left a three-way Foley catheter with saline irrigation at the end of the procedure. We performed this method under the internal committee agreement and with written informed consents signed by both patients. Both patients were successfully managed by this combined technique. There were no complications during surgery or postoperative period. In 24 h, the urine was clear with the normal yellowish color, so we suspended the irrigation. Clot evacuation is a common situation faced by urologist. Sometimes a large and well-organized clot is difficult to break and evacuate by conventional methods.

Given this situation, we decided to apply the theory proposed by Warlick et al. [2]; we irrigated the bladder with 1.5 L of 0.3% of hydrogen peroxide in normal saline. Hydrogen peroxide is medically used as an antiseptic solution for infections and wound irrigations [5]. The role of hydrogen peroxide over the clot is not yet so well understood.

understood; however, the inhibition of adenosine phosphate and oxidative effects of hydrogen peroxide are some of the theories proposed \([6,7]\). In our experience, the way hydrogen peroxide may work is by contracting the clot as well as giving a more liquid consistency (Figs. 2A and 2B).

Another important effect that hydrogen peroxide cause is hemostasis due to the activation of the tissue factor, platelet aggregation regulating the contractility and function of the barrier of the endothelial cells and by stimulating the activation of the platelet-derived growth factor \([6,8]\). Several articles demonstrated that there were no adverse effects with the use of hydrogen peroxide in the bladder \([2,9,10]\). The concentration used in this study was the one proposed by Warlick et al. \([2]\). There could be a big concern in what are the potential damages to the bladder mucosa; nevertheless, Xu et al. \([9]\) mentioned that in cystoscopy performed 6 months posterior to the bladder irrigation with hydrogen peroxide no abnormalities were found.

Goel and Dalela \([3]\) applied suction to the bladder to evacuate the clots of 25 patients without having any complication with a suction bridge method. We believe this method is very efficient, however, not all hospitals have this equipment. Applying the knowledge used to make this bridge, we came up with the idea of using the endotracheal suction catheter used by anesthesiologists. This catheter has a French measure as the conventional Foley catheters; at the tip, it has openings so that the secretions could pass at the other side an air vent so that we can regulate suction. Another advantage is that this catheter has measures similar to Foley catheters and goes up to 18 Fr. Also, the endotracheal suction catheter has the same manageable consistency of a Foley catheter so we can reduce the bladder perforation risk. This study has certain limitations because there is no control group and it is a non-randomized study. Also, this study is a single-center study including a small number of patients.

We were the first group that combined methods to manage a well-organized bladder clot. We believe that the suction method is very useful and combined with the oxidizing process of the hydrogen peroxide potentiates, even more, the suction method. Our novel and reproducible idea has the advantage that is a material commonly found in hospitals. A prospective study should be done to validate our combined method.
