Knowledge, attitude and practices study on reproductive health among adolescent school students in a city of Central India

Anil Singh Baghel¹, Sanjay Kumar Chourasiya²*, Ravindra Pal³, Ruchika Sharda²

ABSTRACT

Background: Ujjain is holy city of Lord Mahankal. It is an ancient city on the eastern bank of the Kshipra River. There were total 2508 students studying in 11th and 12th standards in various higher secondary schools of Ujjain city. Reproductive health is a crucial part of general health and a central feature of human development. It is a reflection of health during childhood and crucial during adolescence and adulthood, sets the stage for health beyond the reproductive years. Adolescence is a complex period of myriad of physiological as well psychological changes. This is a time for them to prepare for making responsibilities, a time of exploration and widening horizons and a time to ensure healthy all-around development. Adolescents lack knowledge regarding reproductive health problems. The present study is conducted to assess the knowledge, attitude and practices regarding selected aspects of reproductive health with special reference to knowledge of Reproductive tract infections (RTI) among adolescent school students.

Methods: This was a cross sectional study carried out among randomly selected school students of Ujjain city.

Results: It was observed that 86% of the students had adequate knowledge in the area of pregnancy and care during pregnancy. The mean score percentage of reproductive tract infection was found to be 56.92%. 90.50% students agreed that Menstruation is normal phenomenon.

Conclusions: There is need of imparting sex education in schools across the country with the help of specially trained teachers and peer educators.

Keywords: Adolescent, Reproductive health, Reproductive tract infection, Sex education

INTRODUCTION

The International conference on population and development (ICPD) in 1994 was given an international consensus definition to sexual and reproductive health. It defined reproductive health as a state of complete physical, mental and social well-being in all matters relating to the reproductive system and its functions and processes.¹

Reproductive health is a crucial part of general health and a central feature of human development. It does not start out from a list of diseases or problems-sexually transmitted diseases, maternal mortality-or from a list of programmes-maternal and child health, safe motherhood, family planning. Reproductive health instead must be understood in the context of relationships: fulfilment and risk; the opportunity to have a desired child or alternatively, to avoid unwanted or unsafe pregnancy.²

Adolescence is a complex period of myriad of physiological as well psychological changes. This is a time for them to prepare for making responsibilities, a time of exploration and widening horizons and a time to ensure healthy all-around development.
According WHO, adolescence is a period of a life between 10 to 19 years.  

- Early adolescence: 10-14 years.  
- Late adolescence: 15-19 years.

The largest generation of adolescents in history 1.2 billion strong is preparing to enter adulthood in rapidly changing world. According to WHO estimates, one in every five people in the world is an adolescent.  

Focusing on adolescent reproductive health is both a challenge and an opportunity for health care providers. While adolescence generally is a healthy period of life, many adolescents are less informed, less experienced, and less comfortable accessing health services for reproductive health than adults.  

Adolescents often lack basic reproductive health information, knowledge, and access to affordable confidential health services for reproductive health. Many do not feel comfortable in discussing reproductive health with parents. The absolute number of adolescents aged 10-19 years in India is 25,31,60,473 as per Census 2011 comprising 20.9 per cent of the total population of the country. Of these, 133.4 million are boys and 119.8 are girls, constituting 52.7 per cent and 47.3 per cent of the adolescent population respectively.  

Adolescent lack knowledge regarding reproductive health problems which lead to depression, mental stress and seeking of advice from quacks and incompetent persons for knowledge on the reproductive health problem which is undesirable. Moreover, the routine health services do not provide adequate care of the adolescent health problem which exaggerates the problems further. Understanding their awareness about related issues will help us in giving education based on need. Keeping in view the above-mentioned facts present study is conducted to assess the knowledge, attitude and practices regarding selected aspects of reproductive health with special reference to knowledge of reproductive tract infections (RTI) among adolescent school students.  

METHODS  

Study type  

This was a cross sectional study carried out among selected school students of Ujjain city of Madhya Pradesh state of central India. Ujjain is holy city of Lord Mahankal. It is an ancient city of Malwa region, on the eastern bank of the Kshipra River.  

Study setting  

The study was conducted in three randomly selected higher secondary schools. Amongst which one was boys’ school, one was girls’ school and one was co-education school. Schools were visited when students are easily available and non examination time. The study period was from December 2017 to June 2018.  

Study universe  

Students of age group of 16-19 years enrolled in selected higher secondary school during the data collection period of study comprised the study universe. As per the records obtained from the office of District Education Officer, Ujjain there were total two thousand five hundred eight (2508) students studying in eleventh (11th) and twelfth (12th) standards in various higher secondary schools.  

Sampling  

The sample size derived for the study was according to probable percentage of knowledge score more than 50% was about 41% in a pilot study conducted on hundred (100) school students (Fifty were boys and fifty were girls). The pilot study was done on students from other schools with the help of self-administered structured questionnaire, and prevalence of knowledge of reproductive health among study subject was used for calculating the final sample size of the study.  

The formula applied for sample size calculation was  

\[ n = \frac{4pqL}{L^2} \]  

Where, \( p \)=probable percentage of knowledge, \( q = 1-p \) and \( L \)=allowable error.  

For this study \( L \) was presumed to be 10% of \( p \) giving a power of \( (1-L) \) i.e., 90% to study. \( p \) was taken as 41% on the basis of pilot study.  

Sample size=  

\[ \frac{4 \times 41 \times 0.59}{0.41^2} \]  

The sample size derived was 576. For equal distribution purpose it is rounded to 600. Equal no of study participants was taken i.e., 200 students selected from each school by using random sampling method.  

Data collection  

Data collection was done with the help of a self-administered structured questionnaire consist of socio-demographic part, questions regarding selected aspects of reproductive health, to assess the knowledge of reproductive tract infection and to assess the practices related to menstrual hygiene and sexual behaviour among selected students. A Hindi translation of questionnaire based on previously developed validated tools was carried out using forward translation and the backward translation process. Forward translation was carried out by expert of community medicine having experienced in English to Hindi translation than it was presented in front of expert’s panel having knowledge of both language and their suggestions was considered for betterment of questionnaire. Backward translation was carried out by
two independent translators and discrepancies were resolved with expert advice. Before starting the collection of data, permission from District Education authorities and the principles of respected schools was taken and they were explained about purpose of the study. Instructions were explained to fill up the structured questionnaire. Questionnaires were checked for completeness and correctness before entering into the work sheet. Data validation checks were performed at a regular interval for data entered into the worksheet of Microsoft excel. The data collected were analysed with SPSS version 18. Reliable tests wherever required used for analysis. The level of significance was taken as p<0.05. The study was approved by the Institutional Ethical Committee of Ruxmaniben Deepchand Gardi Medical College, Ujjain and a written informed consent was obtained from parents/guardians of the study participants. Students were assured of confidentiality of the study.

RESULTS

A total of 600 students were selected for the study. Amongst them 35.2% of the students were of 17 years old. 71.2% of students were from urban area and 66.8% were residing with family. Regarding subjects 32.0% of students were from biology and 68.0% were from other subjects. Majority of them belongs to Hindu (79.5%) religion (Table 1).

Table 2 reveals mean, standard deviation (SD) and mean score percentage of knowledge on reproductive health over 5 dimensions. Findings shows that mean percentage of overall knowledge score in the area of reproductive health was 60.73%. Among these 5 dimensions more knowledge was found to be in the area of pregnancy and care 86%. The mean score percentage of contraceptive method is 58.50%, in the area of anatomy and physiology of reproductive system was 57.90% and in the area of reproductive tract infection was 56.92%. The least knowledge score was of menstruation which was about 56.20%.

As shown in Table 3 that mean score of female’s students regarding knowledge on reproductive health found to be comparatively more than the male students. Independent ‘t’ test was used for assessing the statistical significance and it was found to be statistically significant at p<0.05.

Table 4 shows that mean score knowledge of 12th standard student found to be comparatively more than the 11th standard. Independent ‘t’ test was used for assessing the statistical significance and it was found to be not significant at p<0.05.

The above table shows that mean score knowledge of RTI in adolescent female found to be comparatively more than the adolescent male. Independent ‘t’ test was used for assessing the statistical significance and it was found to be significant at p<0.05.

| Characteristics | N (%) |
|-----------------|-------|
| **Age (in completed year)** | |
| 16 | 189 (31.5) |
| 17 | 211 (35.2) |
| 18 | 134 (22.3) |
| 19 | 66 (11.0) |
| **Sex** | |
| Male | 329 (54.8) |
| Female | 271 (45.2) |
| **Residence** | |
| Urban | 427 (71.2) |
| Rural | 173 (28.8) |
| **Types of residence** | |
| With family | 401 (66.8) |
| Alone in rented room | 51 (8.5) |
| In hostel | 148 (24.7) |
| **Education** | |
| 11th | 307 (51.2) |
| 12th | 293 (48.8) |
| **Subject** | |
| Biology | 192 (32.0) |
| Maths | 205 (34.2) |
| Commerce/art | 203 (33.8) |
| **Religion** | |
| Hindu | 477 (79.5) |
| Muslim | 105 (17.5) |
| Sikh | 7 (1.2) |
| Christian | 11 (1.8) |
| **Type of family** | |
| Nuclear | 256 (42.7) |
| Joint | 208 (34.7) |
| Third generation | 136 (22.6) |
| **Selected personal hobbies** | |
| Browsing internet | 77 (12.8) |
| Watching cinema | 84 (14.0) |
| Sports/games | 231 (38.6) |
| Reading books | 167 (27.8) |
| Others | 41 (6.8) |

Table 6 represents the mean score of knowledge on reproductive health over the different categories of social class. To assess the significance of mean score of knowledge over the five categories of social class, ANOVA test (Analysis of variance) was used and it was found to be not significant at p<0.05 level.

Figure 1 shows the attitude of participants, as shown in the figure most of the students 90.50% agreed that “menstruation is normal phenomenon”. Regarding “cleanliness of genital organ is important”, it was observed that most of the students 95.40% were agree.

Table 6: Mean score of knowledge amongst students on reproductive health by social class (n=600).

| Social class | No. | Mean | S.D. | F value | P value |
|--------------|-----|------|------|---------|---------|
| I            | 105 | 20.90| 6.09 | 2.331   | 0.055   |
| II           | 184 | 20.65| 6.80 |         |         |
| III          | 202 | 19.74| 6.96 |         |         |
| IV           | 101 | 18.52| 6.38 |         |         |
| V            | 8   | 21.62| 7.84 |         |         |

Around 15% of students in all the three streams i.e., biology, maths and commerce have experienced masturbation while homosexuality is practiced in 8.3% in biology group, 4.4% in maths, and 5% in commerce, while sexual fantasy is experienced by 12.5% in biology group, 10.2% in maths group, and 8.4% in commerce/arts group. Around 66% students in biology group, 70% in maths and commerce/arts had no response. It also shows that 93% students in biology group, 90% student’s maths group, 90% students in commerce group have not practiced or practicing sexual intercourse.

A total of 72.69% of girl’s student use sanitary napkin during menses, while only 65% of girls from girl’s school disposed used material in waste bin. Practices of changing pad twice daily followed by only 62% in girl’s school compared to 80% in co-education girls’ students.

DISCUSSION

Reproductive health remains a critical universal issue for all humans in the world. The subject of sex in developing countries like India has been neglected and is still considered a taboo. The sexual and reproductive health of adolescent people remains a neglected area of public health. Adolescents are at high risk of unintended pregnancy, RTIs, STDs including HIV/AIDS, because of their lack of information, limited access to sexual and reproductive health information and services. The present study is an attempt to assess the knowledge, attitude and practices about reproductive health with special reference of knowledge of RTIs in adolescent’s school students in a city of central India, so as to find areas of interventions and an effective sexual and reproductive health education programme.

In present study we found that the mean percentage of knowledge of anatomy and physiology of reproductive system was 57.9%. Minimum mean score knowledge of study subjects regarding menstruation was 56.2%. Most of the study subjects i.e., 86% had more knowledge in the area of pregnancy and care. 58.5% of the subjects had knowledge in the area of contraceptive method. 56.9% of the subject had knowledge in the area of RTI. Over all mean score knowledge of adolescent students on the selected aspects of reproductive health was 60.73% (SD=6.71). Sophia et al in their study observed mean, SD and mean score percentage of knowledge on reproductive health over 4 dimensions, their finding shows that mean score percentage of overall knowledge in the area of reproductive health was 50.7%. They found that among these 4 dimensions more knowledge was to be in the area of pregnancy and care i.e., 58.8%. In contrast to our study
they found mean score percentage of menstrual hygiene, in the area of anatomy and physiology of reproductive health and about family planning was 53.7%, 49.7% and 42.2% respectively. Similarly, Handa et al in their study reported that the mean percentage score obtained by students was 60.39% for human reproductive system and 63.01% for sexual growth and development during puberty. In contrast to our study, a study conducted by Rizwan et al among married women in rural Haryana found that the knowledge about RTIs among them was poor. Almost 47% had not heard about RTI. No one knew the actual cause of RTIs and many did not know the effects of RTIs on women's health. The highest mean percentage score 62.20% in the area of reproductive tract infection, indicate that minimum awareness deficit existed in this area.

In our study response to statement “masturbation is harmful for health”, we observed that 67.20% of the students were disagree it is harmful but 32.80% students were agreed. In our study we also find that there is significant relation between the knowledge of RTI and sex of participants. Female have more knowledge than male students. There exists a significant relation between the knowledge on RTI and subjects have chosen Biology as their core subject. It was found to be significant at p<0.05. There is a significant relation between the knowledge on RTI and type of school. Independent ‘t’ test was worked out to determine the statistical significance of the mean score, it was found to be significant at p<0.05. In contrast to our study, study conducted by Awasthi et al 1980 on school going teenagers, showed that males had better knowledge on biological aspect of reproduction. Students of higher age group (17-19 years) and lower socio-economic status had better knowledge. Female students had better knowledge on psychological aspect of reproduction sex, but males scored better on knowledge about reproductive system. Similar to our study Sophia et al 2005 in their study observed that the score of subjects those who are studying science was found to be 52.7 which is comparatively more than the mean score of students those who are chosen arts as a subject 39.43.

In present study response to statement “sex with multiple partners can cause STDs”, we found that most of the students (78.20%) were agree but 21.80% students were disagreed. In co-education schools 88% of students agreed that sex with multiple partners can cause STDs while it is 75% in Boys and Girls school, in contrast to these Wilberforce et al in their study on 400 non-medical university students found that 89.25% knew that sex with multiple partner is predisposing factors for STD. The present study found that 94% of students knew that condom will prevent the spread of HIV/AIDS infection in contrast to our study Mittal K et al found that only 11.3% of the girls knew correctly about safe sexual intercourse. There are very few studies from India that evaluated masturbation among girls and boys. In our study we found that 67.20% of the students were disagree that masturbation is harmful for health, Shashikumar et al (1998) in their study among Indian urban school adolescents found that more boys (45.9%) than girls (12.7%) indulged in the practice of masturbation, only 14% boys and 9.2% girls were concerned about its effects on health. In contrast to our study Lal et al reported 51.2% boys and 15.3% girls disagreeing that masturbation is harmful. Similarly study conducted by Francis as more than 60% girls were not knowing about masturbation and about 20% thought that it is unhealthy or dirty. The fact that menstruation is normal phenomenon was known to 90% of our study subjects.

**Limitations**

Since the study was confined to 600 adolescent students of 3 selected government schools only so limits generalization. The questionnaire used to collect information on knowledge, attitude and practices of adolescent students regarding reproductive health was structured which accounted for a restricted response.

**CONCLUSION**

In our study we found that the baseline knowledge of the adolescent in most of the aspects of the reproductive health was low. This study highlights the need for imparting training of the students in reproductive health education.
