The impact of exposure to free feeding concentrations of triflumezopyrim to the red imported fire ant, *Solenopsis invicta*, in maximum residue tolerances for 56 days was investigated to understand whether triflumezopyrim, a novel neonicotinoid, poses unacceptable risks to the environment. Our results demonstrated that neither 0.5 μg/ml nor 0.2 μg/ml triflumezopyrim have a significant impact on the growth of the *S. invicta* colony and their food consumption (sugar water and locusts) during the length of treatment. Whiles both 0.5 μg/ml and 0.2 μg/ml triflumezopyrim improved the grasping ability of *S. invicta*, and 0.5 μg/ml not 0.2 μg/ml triflumezopyrim increased their rate of locomotion. In addition, although 0.5 μg/ml and 0.2 μg/ml triflumezopyrim increased their individual aggressiveness index, the probability of the survival of *S. invicta* was not impacted by triflumezopyrim treatments in aggressive group encounters. This study suggests that triflumezopyrim did not have a negative impact on the fitness of *S. invicta* at 0.5 μg/ml and 0.2 μg/ml exposures.

Abstract
The impact of exposure to free feeding concentrations of triflumezopyrim to the red imported fire ant, *Solenopsis invicta*, in maximum residue tolerances for 56 days was investigated to understand whether triflumezopyrim, a novel neonicotinoid, poses unacceptable risks to the environment. Our results demonstrated that neither 0.5 μg/ml nor 0.2 μg/ml triflumezopyrim have a significant impact on the growth of the *S. invicta* colony and their food consumption (sugar water and locusts) during the length of treatment. While both 0.5 μg/ml and 0.2 μg/ml triflumezopyrim improved the grasping ability of *S. invicta*, and 0.5 μg/ml not 0.2 μg/ml triflumezopyrim increased their rate of locomotion. In addition, although 0.5 μg/ml and 0.2 μg/ml triflumezopyrim increased their individual aggressiveness index, the probability of the survival of *S. invicta* was not impacted by triflumezopyrim treatments in aggressive group encounters. This study suggests that triflumezopyrim did not have a negative impact on the fitness of *S. invicta* at 0.5 μg/ml and 0.2 μg/ml exposures.

Introduction
Neonicotinoids are insecticides that act on the nicotinic acetylcholine receptor (nAChR) of insects; it exhibits good activity on sap-sucking pests and comprises over 30% of insecticide sales in the world (Hladik et al., 2018; Ihara & Matsuda, 2018). However, the negative impact of neonicotinoids on non-target organisms at their sublethal concentrations is of increasing concern (Butcherine et al., 2019; Wang et al., 2018). Research has shown that neonicotinoids have adverse impacts on pollinator insects, especially honeybees, and three types of this chemical are currently banned from the European Union, including imidacloprid, thiamethoxam and clothianidin (Ihara & Matsuda, 2018; Pisa et al., 2015).

Current, novel neonicotinoids were developed including sulfoxaflor, flupyradifurone, and triflumezopyrim. Researchers have considered the safety of these new neonicotinoids over other neonicotinoids for non-target insects, especially honeybees. Pan et al. (2017) found that 1.0μg/ml sulfoxaflor reduced aggressiveness, colony growth, and food consumption of the fire ant Solenopsis invicta, while Siviter et al. (2019) found that acute sulfoxaflor exposure did not have negative impacts the olfactory conditioning and working memory of bees. Research showed that flupyradifurone impairs olfactory learning, motor abilities, and the survival of honeybees, including Apis mellifera carnica, A. mellifera ligustica, and A. cerana at even field-realistic doses (Hesselbach & Scheiner, 2019; Tan et al., 2017; Tosi & Nieh, 2019).

Triflumezopyrim is developed by DuPont Crop Protection and is effective against sap-sucking pests (Cordova et al., 2016; Zhang, 2017; Zhang et al., 2017). It was registered in China, Korea, and the Philippines in 2016 and Pyraxalt™ 10% triflumezopyrim SC, the commercial product, was brought to market in China in 2017 (http://news.agropages.com/News/NewsDetail---19109.htm, access on 2019-6-2; http://www.agroinfo.com.cn/other_detail_4668.html, access on 2019-6-2). Zhu et al. (2018) found that triflumezopyrim is an effective insecticide for suppressing plant hopper populations and is harmless to their natural enemies including Anagrus nilaparvatae, Cytorhinus lividipennis, Paederus fuscipes, Pirata subpiraticus, Ummeliata insecticeps, Hylyphantes graminicola, and Pardosa pseudoannulata. Since sulfoxaflor and flupyradifurone were reported to have negative effects on non-target insects, the effects of triflumezopyrim on non-target insects deserves greater attention.

Ants are an important species and a crucial member of their ecosystem; their disruption would negatively impact the health of the ecosystem (Toro et al., 2012). Imidacloprid can change the foraging and competitive behaviors of Lasius niger and L. flavus at sublethal concentrations, which may alter the structure and dynamics of ant communities after oral treatment (Thiel & Köhler, 2016). 1 μg/ml imidacloprid oral treatment reduced the aggressive behavior of the native ant, Monomorium antarcticum, to the invasive ant, Linepithema humile, which may facilitate a successful invasion by the invasive species (Barbieri et al., 2013). Ants are important predators and terrestrial herbivores with a large amount of soil contact and were exposed to neonicotinoids by oral exposure through plant ingestion as well as by contact exposure through contaminated soil (Hölldobler & Wilson, 1990).

The red imported fire ant, S. invicta, is a well-studied ant species making it an ideal model on which to study the sublethal effects of neonicotinoids on ants (Vinson, 2013; Wurm et al., 2011). S. invicta is an active and
efficient predator of pests in agroecosystems despite its negative effects on public health, agriculture, and biodiversity (Harvey & Eubanks, 2004; Vogt et al., 2001; Wang et al., 2016). In this study, we exposed S. invicta colonies to residue limits of triflumezopyrim and evaluated the impact of exposure on their fitness. The objective of the study was to determine the effects of the maximum residue limit of triflumezopyrim on the fitness of the colony and the behavior of workers.

Materials & Methods

Insects and insecticide

Red imported fire ants, Solenopsis invicta, were collected from an organic farm in Conghua County, Guangzhou, China and reared at the Red Imported Fire Ant Research Centre at the South China Agricultural University. S. invicta colonies were provided with a 10% w/w sugar water solution and frozen locusts Locusta migratoria. The social form of S. invicta colonies were determined using methods of Shoemaker & Ascunce (2010), and only polygyne colonies were used in this experiment. All bioassays were conducted under laboratory conditions, and all colonies were reared in the laboratory at least 1 week prior to the start of the experiment.

The commercially available insecticide, Pyraxalt™ 10% triflumezopyrim SC (DuPontTM Crop Protection, Shanghai, China), was used in all experiments.

Effect of triflumezopyrim on S. invicta food consumption and colony growth

The Environmental Protection Agency (EPA) of the United States establishes tolerances for the residues of triflumezopyrim in rice grains and rice hulls of 0.4 ppm and 1.0 ppm, respectively (https://www.federalregister.gov/documents/2017/10/16/2017-22356/triflumezopyrim-pesticide-tolerances, accessed on 2019-6-4). Therefore, we used 0.5 and 0.2 μg triflumezopyrim/ml for the residue tolerances of triflumezopyrim based on the regulatory requirements of the EPA.

Pyraxalt™ is advertised to provide up to 25 days of consistent hopper control (http://www.dupont.com/products-and-services/crop-protection/pyraxalt-insect-control.html, access on 2019-6-2). The estimated average life span of minor, medium, and major workers of S. invicta is 45 days, 75 days, and 135 days, respectively (Calabi & Porter, 1989). In light of these two combined factors the experiment was conducted over 8 weeks.

The experimental method was reflective of the work of Pan et al. (2017) in which a colony was divided into the same weight (> 20g), and each subcolony contained workers, brood, larva, pupa, and at least one functional queen. Each subcolony then received either the control 10% w/w sugar water or a single concentration of triflumezopyrim (0.2 or 0.5 μg/ml) in 10% w/w sugar water; solutions were provided in a 15 ml glass tubes with a cotton stopple. Subcolonies received a sufficient amount of locusts. The weight of each subcolony was taken every 7 days to evaluate the effect of triflumezopyrim on colony growth of S. invicta. The accumulated percentage weight loss of each subcolony was calculated after 7, 14, 21, 28, 35, 42, 49, and 56 days of treatment (Pan et al., 2017). Sugar water and locust consumption (mg sugar water or locust per g ant) was also
calculated for each subcolony at 1, 7, 14, 21, 28, 35, 42, 49, and 56 days. Water evaporation was also estimated. Four colonies were used in this experiment.

**The effect of triflumezopyrim on active behavior of *S. invicta***

We evaluated the effect of triflumezopyrim on *S. invicta* behavior by measuring their grasping ability and walking speed after 56 days of treatment. The experiment method was reflective of the method used by Huang et al. (2016) and Wang et al. (2015).

To test the grasping ability of the fire ant, 10 workers varying in size from the treatment or control subcolony were placed on an A4-sized paper. The paper was gently turned over 180 degrees after 10s and held in place for 10s. Workers falling from the paper was considered to have lost their grasping ability. The grasping ability was evaluated by grasping rate using the following formula: grasping rate (%) = (number of workers possessing grasping ability/total number of workers in test) × 100%. Each subcolony from each treatment and control group was tested 3 times.

To test the walking speed of the fire ants, a tray with a fire ant subcolony was connected to a forging arena (tray, L×W×H, 41.75×27.5×12 cm) by a wood bridge. The bridge consists of two 20 cm vertical segments and one 20 cm horizontal segment. The walking speed of the workers was measured by recording the time needed for an ant to walk across the 20 cm horizontal segment of the bridge. The method was described by Wang et al. (2015). A total of 25 workers were measured from each subcolony.

**The effect of triflumezopyrim on the aggressiveness of *S. invicta***

In this experiment, we assessed the effect of sublethal doses of triflumezopyrim on the aggressive behavior of *S. invicta*. The experimental method was reflective of the method used by Pan et al. (2017). The aggressiveness level of *S. invicta* was assessed when *S. invicta* individuals and colonies were confronted with another ant species, *Pheidole fervida*, at 56 days after treatment. Four *P. fervida* colonies were used.

*S. invicta* and *P. fervida* colonies were paired in interspecific individual or colony interaction tests. The interspecific interaction was quantified using a behavioral assay described by Pan et al. (2017). In interspecific individual aggression, interactions were scored and calculated as described by Rice and Silverman (2013) and Pan et al. (2017). Four replicate experiments were performed for three pairs of colonies with each receiving a dose of triflumezopyrim. Each replicate involved different workers.

Interspecific colony aggression was evaluated using an assay described by Pan et al. (2017). Specially, thirty workers varying in size from pairs of treated *S. invicta* and untreated *P. fervida* colonies were randomly chosen and introduced into a petri dish. Mortality rates of *S. invicta* were recorded after 3 h. Three replicates were performed for three pairs of colonies receiving a dose of triflumezopyrim at the same time. Each replicate involved different workers.

**Statistical analyses**

All data were analyzed using Shapiro-Wilk and Levene's tests for normal distribution and homogeneity of variances, respectively. If data were normally distributed and had similar variances, then the means of measured variables were compared by one-way analysis of variance (ANOVA). Significant ANOVA results
were corrected for multiple comparisons using LSD's method. Non-normally distributed data were analyzed using a nonparametric Kruskal-Wallis test to compare medians; differences significant at the 0.05 significance level were subjected to a Mann-Whitney test for pairwise comparisons. All statistical analyses were performed using SPSS version 18.0 (SPSS Inc., Chicago, IL, USA).

Results

Effect of triflumezopyrim on *S. invicta* colony growth

There is no significant difference in the survival of *S. invicta* colonies among 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and the control (Fig. 1; day 7, LSD test, $F_{2,9} = 0.404$, $P = 0.679$; day 14, LSD test, $F_{2,9} = 0.116$, $P = 0.892$; day 28, LSD test, $F_{2,9} = 0.089$, $P = 0.916$; day 35, LSD test, $F_{2,9} = 0.298$, $P = 0.749$; day 42, LSD test, $F_{2,9} = 0.746$, $P = 0.501$; day 49, LSD test, $F_{2,9} = 0.488$, $P = 0.629$; day 56, LSD test, $F_{2,9} = 0.527$, $P = 0.608$). After 56 days of treatment, the accumulated percentage weight losses were 51.40%, 50.65%, and 58.46% in colonies treated with 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and controls, respectively.

Effect of triflumezopyrim on *S. invicta* food consumption

There is no significant difference in sugar consumption between ants treated with 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and the control (Table 1; day 1, LSD test, $F_{2,9} = 0.946$, $P = 0.418$; day 7, LSD test, $F_{2,9} = 0.673$, $P = 0.534$; day 14, LSD test, $F_{2,9} = 0.322$, $P = 0.733$; day 21, LSD test, $F_{2,9} = 1.396$, $P = 0.296$; day 28, LSD test, $F_{2,9} = 2.129$, $P = 0.175$; day 35, LSD test, $F_{2,9} = 0.283$, $P = 0.760$; day 42, LSD test, $F_{2,9} = 1.472$, $P = 0.280$; day 49, LSD test, $F_{2,9} = 1.768$, $P = 0.225$; day 56, LSD test, $F_{2,9} = 0.782$, $P = 0.486$).

Triflumezopyrim treatments do not have an impact on locust consumption (Table 2; day 1, LSD test, $F_{2,9} = 0.004$, $P = 0.996$; day 7, LSD test, $F_{2,9} = 0.172$, $P = 0.845$; day 14, LSD test, $F_{2,9} = 0.539$, $P = 0.601$; day 21, LSD test, $F_{2,9} = 1.726$, $P = 0.232$; day 28, LSD test, $F_{2,9} = 1.443$, $P = 0.286$; day 35, LSD test, $F_{2,9} = 3.691$, $P = 0.068$; day 42, LSD test, $F_{2,9} = 0.728$, $P = 0.509$; day 49, LSD test, $F_{2,9} = 1.940$, $P = 0.199$; day 56, LSD test, $F_{2,9} = 0.089$, $P = 0.915$).

Effect of triflumezopyrim on *S. invicta* activity behavior

After 56 days of treatment the grasping rate of workers was 88.67±2.14%, 90.33±1.67%, and 71.67±5.13% in 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and the control, respectively. The grasping rate of workers in the triflumezopyrim treatment is higher than that of the control (0.5 μg/ml triflumezopyrim and control, Mann-Whitney test, $U = 27$, $P = 0.009$; 0.2 μg/ml triflumezopyrim and control, Mann-Whitney test, $U = 18$, $P = 0.002$).

After 56 days of treatment the walking speed of workers was 9.50±0.22mm/s, 9.39±0.23mm/s, and 9.41±0.38mm/s in 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and control, respectively. The walking speed of workers in 0.5 μg/ml triflumezopyrim treatment was higher than that of the control (0.5 μg/ml triflumezopyrim and control, Mann-Whitney test, $U = 27$, $P = 0.009$; 0.2 μg/ml triflumezopyrim and control, Mann-Whitney test, $U = 18$, $P = 0.002$).
**Effect of triflumezopyrim on *S. invicta* aggressiveness**

After 56 days of treatment the aggressiveness indices of *S. invicta* workers was 1.58±0.28, 1.31±0.29, and 0.47±0.20 in 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and the control, respectively. The aggressiveness index of *S. invicta* was significantly increased by triflumezopyrim treatment (0.5 μg/ml triflumezopyrim and control, Mann-Whitney test, U=57.5, P=0.004; 0.2 μg/ml triflumezopyrim and control, Mann-Whitney test, U=75.5, P=0.030).

In the group aggression experiment, the mortality of *S. invicta* workers was 6.33±1.51%, 6.67±1.80%, 7.33±2.14% in 0.5 μg/ml triflumezopyrim, 0.2 μg/ml triflumezopyrim, and control after 56 days of treatment, respectively; there is no significant difference among triflumezopyrim treatments and the control (LSD test, F(2,33)=0.77, P=0.926).

**Discussion**

The negative impact of neonicotinoids on non-target organisms is a global concern. As a novel neonicotinoid, the impact of triflumezopyrim on non-target insects deserves attention. Zhu et al. (2017) found that 62.5 μg a.i/ml triflumezopyrim does not negatively impact the parasitic wasp *Anagrus nilaparvatae* after 30 min of exposure. Our study showed that 0.2 and 0.5 μg/ml triflumezopyrim, which are near the tolerance levels for the residue of triflumezopyrim in rice grains and hulls, does not have a negative effect on the colony growth and food consumption (sugar water and locusts) of fire ants after 56 day of exposure. Although the 0.2 and 0.5 μg/ml triflumezopyrim treatments increased the grasping ability and individual aggressiveness of fire ant workers, and 0.5 μg/ml triflumezopyrim treatment increased the walking speed of fire ants, triflumezopyrim treatment did not impact the mortality of fire ant workers in the group aggression experiment.

Rondeau et al. (2014) suggested that testing for the chronic effects of pesticides should be extended to 30 days or more for social insects. The estimated average life span of minor, medium, and major workers is 45 days, 75 days, and 135 days, respectively (Calabi & Porter, 1989). Our experiments were conducted for 56 days in light of the abovementioned factors. We used three experimental parameters to investigate the impact of tolerances for the residues of triflumezopyrim exposure on fire ant colony growth, food consumption, and activity. The three parameters were chosen because they are related to the fitness of the fire ant colony. For example, walking speed and aggressiveness is involved in competition for food, and the protection and expansion of territory, which are indicators of competitiveness in ants (Holway, 1999).
Our results showed that the treatments of 0.2 and 0.5 μg/ml triflumezopyrim increased the grasping ability and aggressiveness of the individual worker and 0.5 μg/ml triflumezopyrim increased the walking speed of the fire ant. Other neonicotinoids have a similar effect. For example, thiamethoxam at 108.1 ng/g exposure caused a short-term locomotor hyperactivity of the carabid beetle *Platynus assimilis* (Tooming et al., 2017). The lower concentration of imidacloprid, such as 10 ng or 1.25 ng/insect treatment, resulted in a higher locomotor activity of the treated insect (Galvanho et al., 2013; Lambin et al., 2010). França et al. (2017) indicated that insect behavior changes with sublethal doses of pesticides, which may indirectly influence species biology and fitness. However, behavior changes resulting in fire ant fitness for colony growth and group aggression was not impacted based on our data.

Registration information of triflumezopyrim is submitted to many key markets of the world and is now registered for sale in China (http://news.agropages.com/News/NewsDetail---19109.htm). Our study revealed that there is no negative impact of 0.5 μg/ml triflumezopyrim exposure on the colony growth and food consumption of the fire ant. Further studies are needed to determine the conditions under which triflumezopyrim may have a detrimental impact on ants. Our results provide information for the future use of this insecticide on crops in terms of regulations and policy decisions.

**Conclusions**

We found triflumezopyrim, a novel neonicotinoid, did not cause any negative impact on the fitness of the fire ant *S. invicta* at 0.2 and 0.5μg/ml after 56 days of observation. Neither colony growth nor food consumption was influenced by 0.2 and 0.5μg/ml triflumezopyrim. The probability of survival of *S. invicta* was not impacted by triflumezopyrim treatments in aggressive group encounters, although 0.5 μg/ml and 0.2 μg/ml triflumezopyrim increased the individual aggressive index, and 0.5 μg/ml triflumezopyrim increased the moving speed and grasping ability of *S. invicta*. The results imply that the maximum residue limit of triflumezopyrim may have no impact on other non-target ants.
