The smallest singular value of random rectangular matrices with no moment assumptions on entries

Konstantin E. Tikhomirov, University of Alberta, Canada

September 30, 2014

Abstract

Let $\delta > 1$ and $\beta > 0$ be some real numbers. We prove that there are positive $u, v, N_0$ depending only on $\beta$ and $\delta$ with the following property: for any $N, n$ such that $N \geq \max(N_0, \delta n)$, any $N \times n$ random matrix $A = (a_{ij})$ with i.i.d. entries satisfying $\sup_{\lambda \in \mathbb{R}} \mathbb{P}\{|a_{11} - \lambda| \leq 1\} \leq 1 - \beta$ and any non-random $N \times n$ matrix $B$, the smallest singular value $s_n$ of $A + B$ satisfies

$$\mathbb{P}\{s_n(A + B) \leq u\sqrt{N}\} \leq \exp(-vN).$$

The result holds without any moment assumptions on distribution of the entries of $A$.

1 Introduction

In last years, spectral properties of random matrices with fixed dimensions (the corresponding theory is often called non-asymptotic) have attracted considerable attention of researchers, whose efforts have been mostly concentrated on studying distributions of the largest and the smallest singular values. For detailed information on the development of the subject, we refer the reader to surveys [11], [21].

Let $N \geq n$. Given an $N \times n$ random matrix $A$, we employ a usual notation $s_1(A) := \max_{y \in S^{n-1}} \|Ay\|; s_n(A) := \inf_{y \in S^{n-1}} \|Ay\|$. A limiting result of Z.D. Bai and Y.Q. Yin [3] suggests that for an $N \times n$ matrix with i.i.d. mean zero entries with unit variance and a finite fourth moment, its largest and smallest singular values should “concentrate” near $\sqrt{N} + \sqrt{n}$ and $\sqrt{N} - \sqrt{n}$, respectively. In the non-asymptotic setting one is interested, in particular, in finding the weakest possible conditions on random matrices that would imply $s_1 \lesssim \sqrt{N} + \sqrt{n}$ and $s_n \gtrsim \sqrt{N} - \sqrt{n}$ with a large probability.

For a random $N \times n$ matrix $A$ with i.i.d. mean zero subgaussian entries, an elementary application of the standard $\varepsilon$-net argument yields $s_1(A) \lesssim \sqrt{N} + \sqrt{n}$ with an overwhelming probability. Distribution of the smallest singular value when $N \approx n$ requires a more delicate analysis. A. Litvak, A. Pajor, M. Rudelson and N. Tomczak-Jaegermann showed in [7] that if $N$ and $n$ satisfy $N/n \geq 1 + c_1(\ln N)^{-1}$ then $\mathbb{P}\{s_n(A) \leq c_2\sqrt{N}\} \leq \exp(-c_3N)$, where $c_1, c_2$ depend only on variance and subgaussian moment and $c_2$ — on the moments and the aspect ratio $N/n$. The approach initiated in [7] was further developed by M. Rudelson and R. Vershynin who combined it with certain Littlewood–Offord-type
theorems. In [14], Rudelson and Vershynin treated square matrices and later in [13] — rectangular matrices with arbitrary aspect ratio and i.i.d. mean zero subgaussian entries, thereby sharpening and generalizing the result of [7]. We note that the Littlewood–Offord theory has gained an important role in the study of random matrices primarily due to T. Tao and V. Vu (see, in particular, [18]).

Various estimates for the extremal singular values were obtained when studying the problem of approximating covariance matrix of a random vector by the empirical covariance matrix. Answering a question of R. Kannan, L. Lovász and M. Simonovits, the authors of [1] treated log-concave random vectors. Later, the log-concavity was replaced by weaker assumptions (see, in particular, [2], [17], [9], [4]).

Recently, it has become apparent that different conditions are required to bound the largest and the smallest singular value, and these two questions should be handled separately. One of results proved by N. Srivastava and R. Vershynin in [17] provides a lower estimate for the second moment of \( s_n(A) \), where \( A \) is an \( N \times n \) matrix with independent isotropic rows satisfying a \((2 + \varepsilon)\)-moment condition and certain assumptions on the aspect ratio \( N/n \). It is important to note that the conditions imposed on \( A \) are too weak to imply the “usual” upper bound \( s_1(A) \lesssim \sqrt{N} \) with a large probability \( 8 \). This result of [17] was strengthened by V. Koltchinskii and S. Mendelson in [5] under similar assumptions on the matrix. Another theorem of [5] states the following: given an \( n \)-dimensional isotropic random vector \( X \) satisfying \( \inf_{y \in S^{n-1}} \mathbb{P}\{|\langle X, y \rangle| \geq \alpha\} \geq \beta \) for some \( \alpha, \beta > 0 \), there are \( C_1, c_2, c_3 > 0 \) depending only on \( \alpha, \beta \) such that for \( N \geq C_1 n \) and the \( N \times n \) random matrix \( A \) with i.i.d. rows distributed like \( X \), one has \( \mathbb{P}\{s_n(A) \geq c_2 \sqrt{N}\} \geq 1 - \exp(-c_3 N) \).

Some further improvements of the estimates have been obtained in [22]. The assumption of isotropicity of a random vector or, more generally, boundedness of variance of its coordinates is quite natural and appears as part of requirements on a matrix’ rows in all the aforementioned papers. However, for a deeper understanding of non-asymptotic characteristics of random matrices, an important question is whether any moment assumptions on entries are really necessary in order to get satisfactory lower estimates for the smallest singular value.

Unlike in [17] and [5] where the matrix entries within a given row are not necessarily independent, in our paper we consider the classical setting when a rectangular matrix has i.i.d. entries. However, in contrast with all the mentioned results, the lower estimate for the smallest singular value that we prove does not use any moment assumptions; the only requirement is that the distribution of entries satisfies a “spreading” condition given in terms of the Levy concentration function. Moreover, compared to [17] and [5], we significantly relax the assumptions on the aspect ratio of the matrix.

Given a real random variable \( \xi \), the concentration function of \( \xi \) is defined as

\[
Q(\xi, \alpha) = \sup_{\lambda \in \mathbb{R}} \mathbb{P}\{|\xi - \lambda| \leq \alpha\}, \quad \alpha \geq 0.
\]

The notion of the concentration function was introduced by P. Levy [6] in context of studying distributions of sums of random variables. Note that, for a random variable \( \xi \) with zero median satisfying \( \mathbb{E}|\xi|^p \geq m \), \( \mathbb{E}|\xi|^q \leq M \) for some \( 0 < p < q, m, M > 0 \), necessarily \( Q(\xi, \alpha) \leq 1 - \beta \) for some \( \alpha, \beta > 0 \) depending only on \( p, q, m, M \). At the same
time, the condition $Q(\xi, \alpha) \leq 1 - \beta$ for some $\alpha, \beta > 0$ does not imply any upper bounds on positive moments of $\xi$.

The main result of our paper is the following theorem:

**Theorem 1.** For any real $\beta > 0$ and $\delta > 1$ there are $u, v > 0$ and $N_0 \in \mathbb{N}$ depending only on $\beta$ and $\delta$ with the following property: Let $N, n \in \mathbb{N}$ satisfy $N \geq \max(N_0, \delta n)$; $A = (a_{ij})$ be an $N \times n$ random matrix with i.i.d. entries, such that for some $\alpha > 0$ the concentration function of the entries satisfies

$$Q(a_{11}, \alpha) \leq 1 - \beta.$$  \hspace{1cm} (1)

Then for any non-random $N \times n$ matrix $B$ we have

$$\mathbb{P}\{s_n(A + B) \leq \alpha u \sqrt{N}\} \leq \exp(-vN).$$ \hspace{1cm} (2)

Adding a non-random component $B$ in the theorem does not increase complexity of the proof; on the other hand, it demonstrates “shift-invariance” of the lower estimate. Note that the problem of estimating the smallest singular value of non-random shifts of square matrices is important in analysis of algorithms [15], [16], [19], [20].

It is easy to see that a restriction of type (1) is necessary for (2) to hold. Indeed, suppose that for some $N \times n$ matrix $A$ with i.i.d. entries and some numbers $u, v, \alpha > 0$, (2) is true whenever $B = \lambda I$, $\lambda \in \mathbb{R}$. Then, obviously,

$$\mathbb{P}\left\{\sum_{i=1}^{N} (a_{i1} - \lambda)^2 \leq \alpha^2 u^2 N\right\} \leq \exp(-vN), \; \lambda \in \mathbb{R},$$

implying $Q(a_{11}, \alpha u) = \sup_{\lambda \in \mathbb{R}} \mathbb{P}\{|a_{11} - \lambda| \leq \alpha u\} \leq \exp(-v)$.

Our proof of Theorem 1 is based on two key elements: on a modification of a standard $\varepsilon$-net argument for matrices (Proposition 3) and on estimates of the distance between a random vector and a fixed linear subspace that follow from a result of [12] (Theorem 4 and Corollary 6 of our paper). Our method is similar in many aspects to the approach developed in [7] and later in [13], [14]. In particular, as in the mentioned papers, we decompose the unit sphere $S^{n-1}$ into several subsets which are studied separately from one another. On the other hand, our modification of the $\varepsilon$-net argument and its technical realization in regard to splitting a random matrix into “regular” and “non-regular” parts are apparently new.

We will discuss the main idea of the proof more concretely and in more detail at the end of the next section, after we define notation and state the modified $\varepsilon$-net argument.

## 2 Preliminaries

Throughout the text, $(\Omega, \Sigma, \mathbb{P})$ denotes a probability space. Let $N \in \mathbb{N}$. We say that a function $X : \Omega \to \mathbb{R}^N$ is a random vector in $\mathbb{R}^N$ if the preimage under $X$ of every Borel subset of $\mathbb{R}^N$ is $\mathbb{P}$-measurable. For any non-negative integer $n \leq N$, let $\text{Gr}(n, N)$ be the Grassmannian — the set of all $n$-dimensional subspaces of $\mathbb{R}^N$, equipped with
the unique normalized rotation-invariant Borel measure (the Haar measure). A function $V : \Omega \to \text{Gr}(n, N)$ is an $n$-dimensional random subspace of $\mathbb{R}^N$ if the preimage under $V$ of every measurable subset of $\text{Gr}(n, N)$ is $\mathbb{P}$-measurable. It will be convenient for us to extend the last definition by allowing the subspace to have a “variable” dimension: Consider the disjoint union $\bigcup_{k=0}^{n} \text{Gr}(k, N)$, with the measure induced by the Haar measures on each $\text{Gr}(k, N)$, $k = 0, 1, \ldots, n$. Then $V : \Omega \to \bigcup_{k=0}^{n} \text{Gr}(k, N)$ is a random subspace of $\mathbb{R}^N$ of dimension at most $n$ if the preimage under $V$ of every measurable subset of $\bigcup_{k=0}^{n} \text{Gr}(k, N)$ is $\mathbb{P}$-measurable (an example of such a subspace in the text is $V_{A, B}(H, E)$ defined at the end of the section). We say that the random subspace $V$ and a random vector $X$ in $\mathbb{R}^N$ are independent if for every Borel subset $K \subset \mathbb{R}^N$ and a measurable subset $K' \subset \bigcup_{k=0}^{n} \text{Gr}(k, N)$ we have

$$
P\{X \in K \text{ and } V \in K'\} = P\{X \in K\}P\{V \in K'\}.
$$

Given a vector $x \in \mathbb{R}^m$, by $\|x\|$ we denote the standard Euclidean norm and by $\|x\|_{\infty}$ — the $\ell^m_\infty$-norm of $x$. By $S^{m-1}$ (respectively, $B_2^m$) we denote the Euclidean unit sphere (respectively, the closed unit ball) in $\mathbb{R}^m$. Further, for a set $K \subset \mathbb{R}^m$, $d(x, K) = \inf\{\|x - y\| : y \in K\}$ denotes the Euclidean distance between $x$ and $K$. We use the same notation for the distance between two subsets of $\mathbb{R}^m$.

We will sometimes use the standard identification of $N \times n$ matrices and linear operators from $\mathbb{R}^n$ to $\mathbb{R}^N$. In particular, for an $N \times n$ matrix $D$ by $\|D\|$ we mean the operator norm of $D$ treated as the linear operator $D : \ell^N_2 \to \ell^N_2$. For a set $K \subset \mathbb{R}^n$, $D(K)$ is the image of $K$ in $\mathbb{R}^N$ under the action of $D$. For an $N \times n$ matrix $D$, $\text{col}_j(D)$ is the $j$-th column of $D$ and $\text{span}D$ is the linear span of columns of $D$ in $\mathbb{R}^N$. The $N \times n$ matrix of ones is denoted by $\mathbf{1}_{N \times n}$. For a linear subspace $E \subset \mathbb{R}^n$, $E^\perp$ is the orthogonal complement of $E$ in $\mathbb{R}^n$ and $\text{Proj}_E : \mathbb{R}^n \to \mathbb{R}^n$ is the orthogonal projection onto $E$. In the special case when $E$ is the linear span of a subset $\{e_j\}_{j \in J}$ ($J \subset \{1, 2, \ldots, n\}$) of the standard unit basis in $\mathbb{R}^n$, we will often write $x_{\chi, J}$ in place of $\text{Proj}_E(x)$.

In the paper, we define many universal constants and functions that are frequently referred to later in text. For convenience, we add to the name of every such constant or function a subscript indicating the statement where it was defined. For example, $C_{[12]}$ is the universal constant from Lemma [12].

Let $K$ be a subset of $\mathbb{R}^n$ and let $\varepsilon > 0$. A subset $\mathcal{N} \subset K$ is called an $\varepsilon$-net for $K$ if for any $y \in K$ there is $y' \in \mathcal{N}$ with $\|y - y'\| \leq \varepsilon$. We will use a well-known fact that any subset $K \subset B_2^n$ admits an $\varepsilon$-net $\mathcal{N}$ for $K$ with cardinality $|\mathcal{N}| \leq (3/\varepsilon)^n$.

Given an $\varepsilon$-net $\mathcal{N}$ for $S^{n-1}$, the matrix $A + B$ from Theorem [2] trivially satisfies

$$
s_n(A + B) \geq \min\|Ay' + By'\| - \varepsilon\|A + B\|.
$$

This standard $\varepsilon$-net argument is not applicable in our setting as $A + B$ may have a very large norm with a large probability. A modification of the method in such a way that $\|A + B\|$ does not participate in the estimate for $s_n(A + B)$ is an important element of our proof. In this section we provide a “non-probabilistic” form of the argument. Given a non-random $N \times n$ matrix $D$, we shall represent it as a sum of two matrices $D_1$ and $D_2$; then we are able to estimate $s_n(D)$ from below in terms of the norm $\|D_1\|$ of the “regular part” of the matrix $D$ and distances between certain vectors and subspaces in $\mathbb{R}^N$ (determined by matrices $D_1$ and $D_2$). We start with a simpler version of the argument:
Lemma 2. Let $N, n \in \mathbb{N}$, $h, \varepsilon > 0$ and let $D_1, D_2, D$ be $N \times n$ (non-random) matrices with $D = D_1 + D_2$. Further, let $\mathcal{N}$ be an $\varepsilon$-net on $S^{n-1}$ such that for any $y' \in \mathcal{N}$ we have

$$d(D_1y', \text{span}D_2) \geq h.$$ 

Then

$$s_n(D) \geq \inf_{y \in S^{n-1}} d(D_1y, \text{span}D_2) \geq h - \varepsilon\|D_1\|.$$ 

Proof. Choose any $y \in S^{n-1}$ and $y' \in \mathcal{N}$ such that $\|y - y'\| \leq \varepsilon$. Then

$$\|Dy\| = \|D_1y + D_2y\| \geq d(D_1y, \text{span}D_2) \geq d(D_1y', \text{span}D_2) - \varepsilon\|D_1\| \geq h - \varepsilon\|D_1\|.$$ 

By taking the infimum over all $y \in S^{n-1}$, we obtain the result. \hfill \Box

Note that Lemma 2 cannot be used to handle matrices with the aspect ratio less than 2. Indeed, the lower estimate $s_n(D) \geq \inf_{y \in S^{n-1}} d(D_1y, \text{span}D_2)$ is non-trivial only if $\text{span}D_1 \cap \text{span}D_2 = 0$, which is not true when $N < 2n$ and both $D_1$ and $D_2$ have full rank. The following strengthening of Lemma 2 resolves the problem:

Proposition 3. Let $N, n \in \mathbb{N}$, $S \subset S^{n-1}$ and let $D_1, D_2, D$ be $N \times n$ (non-random) matrices with $D = D_1 + D_2$. Further, suppose that the numbers $h, \varepsilon > 0$, a subset $\mathcal{N} \subset \mathbb{R}^n$ and a collection of linear subspaces $\{E_{y'} \subset \mathbb{R}^n : y' \in \mathcal{N}\}$ satisfy the following conditions: 1) $y' \in E_{y'}$ for all $y' \in \mathcal{N}$; 2) for any $y' \in \mathcal{N}$ we have

$$d(D_1y', D(E_{y'}^1 + D_2(E_{y'}))) \geq h;$$

and 3) for any $y \in S$ there is $y' \in \mathcal{N}$ such that

$$\|\text{Proj}_{E_{y'}}(y) - y'\| \leq \varepsilon.$$ 

Then

$$\inf_{y \in S} \|Dy\| \geq h - \varepsilon\|D_1\|.$$ 

Proof. Take any $y \in S$ and let $y' \in \mathcal{N}$ be such that $\|\text{Proj}_{E_{y'}}(y) - y'\| \leq \varepsilon$. Then

$$\|Dy\| = \|D_1(\text{Proj}_{E_{y'}}(y)) + (D(\text{Proj}_{E_{y'}}(y)) + D_2(\text{Proj}_{E_{y'}}(y)))\|$$

$$\geq d(D_1(\text{Proj}_{E_{y'}}(y)), D(E_{y'}^1 + D_2(E_{y'})))$$

$$\geq d(D_1y', D(E_{y'}^1 + D_2(E_{y'}))) - \varepsilon\|D_1\|$$

$$\geq h - \varepsilon\|D_1\|.$$ 

Taking the infimum over $S$, we get the result. \hfill \Box

To apply Proposition 3 we need an estimate for the distance between a random vector in $\mathbb{R}^N$ with independent coordinates and a fixed linear subspace. For any random vector $X$ in $\mathbb{R}^N$ define the concentration function of $X$ by

$$Q(X, h) = \sup_{\lambda \in \mathbb{R}^N} \mathbb{P}\{\|X - \lambda\| \leq h\}, \quad h \geq 0.$$ 

Note that for $N = 1$ the above definition is consistent with that given in the introduction. The following result is proved by M. Rudelson and R. Vershynin in [12]:

$$Q(X, h) = O(h\mathbb{E}\|X\|).$$
Theorem 4 ([12]). Let \( X = (X_1, X_2, \ldots, X_m) \) be a random vector in \( \mathbb{R}^m \) with independent coordinates such that
\[
Q(X_i, h) \leq \eta, \quad i = 1, 2, \ldots, m
\]
for some \( h > 0, \eta \in (0, 1) \). Then for any \( d \in \{1, 2, \ldots, m\} \) and any \( d \)-dimensional non-random subspace \( E \subset \mathbb{R}^m \)
\[
Q(\text{Proj}_E X, h\sqrt{d}) \leq (C_4 \eta)^d,
\]
where \( C_4 > 0 \) is a (sufficiently large) universal constant.

This theorem gives a nontrivial estimate for concentration only for \( \eta \) sufficiently close to zero. Below, we provide an elementary extension of this result covering the case of “more concentrated” coordinates. First, let us recall a theorem of B. Rogozin:

Theorem 5 ([10]). Let \( k \in \mathbb{N}, \xi_1, \xi_2, \ldots, \xi_k \) be independent random variables and let \( h_1, h_2, \ldots, h_k > 0 \) be some real numbers. Then for any \( h \geq \max_{j=1,2,\ldots,k} h_j \),
\[
Q\left(\sum_{j=1}^k \xi_j, h\right) \leq C_5 \left(\sum_{j=1}^k (1 - Q(\xi_j, h_j)) h_j^2\right)^{-1/2},
\]
where \( C_5 > 0 \) is a universal constant.

Now, an easy application of Theorems 4 and 5 gives

Corollary 6. Let \( X = (X_1, X_2, \ldots, X_m) \) be a random vector with independent coordinates such that
\[
Q(X_i, h) \leq 1 - \tau, \quad i = 1, 2, \ldots, m
\]
for some \( h > 0, \tau \in (0, 1) \). Then for any \( d \in \{1, 2, \ldots, m\} \), \( \ell \in \mathbb{N} \) and any \( d \)-dimensional non-random subspace \( E \subset \mathbb{R}^m \) the concentration function of \( \text{Proj}_E X \) satisfies
\[
Q(\text{Proj}_E X, h\sqrt{d}/\ell) \leq \left(C_4 C_5 \sqrt{\ell \tau}\right)^{d/\ell}.
\]

Proof. Let \( X^1, X^2, \ldots, X^\ell \) be independent copies of \( X \) and \( S = (S_1, S_2, \ldots, S_m) = \sum_{j=1}^\ell X^j \). Then, in view of the condition on coordinates of \( X \) and Theorem 5 we obtain
\[
Q(S_i, h) \leq C_5 \left(\ell (1 - Q(X_i, h))\right)^{-1/2} \leq \frac{C_5}{\sqrt{\ell \tau}}, \quad i = 1, 2, \ldots, m.
\]

Then Theorem 4 gives
\[
Q(\text{Proj}_E S, h\sqrt{d}) \leq \left(C_4 C_5 \sqrt{\ell \tau}\right)^d,
\]
and via the definition of \( S \) we get the statement.

Remark 1. Note that for any non-zero \( \tau \) we can choose \( \ell \in \mathbb{N} \) such that the upper estimate for the concentration function provided by Corollary 6 is non-trivial (strictly less than 1). In fact, a slightly weaker version of Corollary 6 still sufficient for our purposes could be proved using the original result of P. Levy from [6] instead of Theorem 5.
As an immediate application of Corollary 2, we prove a statement about peaky vectors. We call a vector \( y \in S_p \) peaky for some \( \theta > 0 \) if \( \| y \|_\infty \geq \theta \). The set of all \( \theta \)-peaky unit vectors in \( \mathbb{R}^n \) shall be denoted by \( S_p^{-1}(\theta) \).

**Proposition 7** (Peaky vectors). Let \( \delta > 1 \) and let \( n, N \in \mathbb{N} \) satisfy \( N \geq \delta n \). Further, assume we are given \( \theta, \gamma > 0 \) and let \( U = (u_{ij}) \) be an \( N \times n \) random matrix with independent entries (not necessarily identically distributed), each entry \( u_{ij} \) satisfying

\[
Q(u_{ij}, 1) \leq 1 - \gamma.
\]

Then

\[
P\left\{ \inf_{y \in S_p^{-1}(\theta)} \| Uy \| \leq h \sqrt[\delta]{N} \right\} \leq \exp(-u_{\theta}N),
\]

where the \( h, u_{\theta} > 0 \) depend only on \( \gamma \) and \( \delta \).

**Proof.** By Corollary 2 for \( d = N - n + 1 \), any \( \ell \in \mathbb{N} \) and any fixed \((n - 1)\)-dimensional subspace \( F \subset \mathbb{R}^N \) we have

\[
P\{d(\text{col}_j(U), F) \leq \sqrt{d/\ell}\} \leq Q(\text{Proj}_{F^\perp}(\text{col}_j(U)), \sqrt{d/\ell}) \leq \left(C \sqrt[\delta]{\ell} \gamma\right)^{d/\ell}, \ j = 1, 2, \ldots, n.
\]

Take \( \ell := \left[4C^2\sqrt{2}/\gamma\right] \). Since for each \( j = 1, 2, \ldots, n \), \( \text{col}_j(U) \) is independent from the span of the other columns of \( U \), from the above estimate we obtain

\[
P\{d(\text{col}_j(U), \text{span}\{\text{col}_k(U)\}_{k \neq j}) \leq h \sqrt{d}\} \leq \exp(-wd), \ j = 1, 2, \ldots, n
\]

for some \( h, w > 0 \) depending only on \( \gamma \). Let

\[
\mathcal{E} = \{ \omega \in \Omega : d(\text{col}_j(U(\omega)), \text{span}\{\text{col}_k(U(\omega))\}_{k \neq j}) > h \sqrt{d} \text{ for all } j = 1, 2, \ldots, n \}.
\]

Then \( \mathbb{P}(\mathcal{E}) \geq 1 - n \exp(-wd) \). Take arbitrary \( \omega \in \mathcal{E} \). For any \( y = (y_1, y_2, \ldots, y_n) \) in \( S_p^{-1}(\theta) \) there is \( j = j(y) \) such that \( |y_j| \geq \theta \), hence

\[
\| U(\omega)y \| = \| U(\omega)(y_je_j) + U(\omega)(y - y_je_j) \|
\geq \theta d \{\text{col}_j(U(\omega)), \text{span}\{\text{col}_k(U(\omega))\}_{k \neq j}\}
> h\theta \sqrt{d}.
\]

Thus,

\[
P\left\{ \inf_{y \in S_p^{-1}(\theta)} \| Uy \| \leq h\theta \sqrt{d} \right\} \leq n \exp(-wd),
\]

and the statement follows. \( \square \)

Next, we introduce two notions important for us that will be used throughout the rest of the text. For any number \( s \in \mathbb{R} \) and any Borel subset \( H \subset \mathbb{R} \), define the \( H \)-part of \( s \) as

\[
s_H = \begin{cases} s, & \text{if } s \in H, \\ 0, & \text{otherwise}. \end{cases}
\]
The “complementary” \( \mathbb{R}/H \)-part of \( s \) will be denoted by \( s_{\overline{H}} \). Obviously, \( s = s_H + s_{\overline{H}} \).

The name and the notation resemble the positive and negative part of a real number; in fact \( s_+ = s_H \) for \( H = [0, \infty) \). For a real-valued random variable \( \xi \) we define the \( H \)-part of \( \xi \) pointwise: \( \xi_H(\omega) = \xi(\omega)_H \) for all \( \omega \in \Omega \). When a variable has a subscript, we will use parentheses to separate the subscript from the \( H \)-part notation, for example \( (\xi_1)_H \) is the \( H \)-part of a random variable \( \xi_1 \). Given a matrix \( A = (a_{ij}) \), its \( H \)-part \( A_H \) is defined entry-wise, i.e. \( (A_H)_{ij} = (a_{ij})_H \) for all admissible \( i, j \).

For any \( N \times n \) matrices \( M, M' \) (whether random or not), a Borel set \( H \subset \mathbb{R} \) and a linear subspace \( E \subset \mathbb{R}^n \) let

\[
V_{M, M'}(H, E) := (M + M')(E^\perp) + (M_{\overline{H}} + M')(E).
\]

Note that \( V_{M, M'}(H, E) \) is a linear subspace of \( \mathbb{R}^N \) of dimension at most \( n \). When the matrices \( M, M' \) are clear from the context, we shall write \( V(H, E) \) in place of \( V_{M, M'}(H, E) \). When one or both matrices \( M, M' \) are random, \( V_{M, M'}(H, E) \) is a random subspace in \( \mathbb{R}^N \) of dimension at most \( n \), that can be formally viewed as a function from \( \Omega \) to the disjoint union of Grassmannians \( \bigsqcup_{k=0}^n \text{Gr}(k, N) \), \( k = 0, 1, \ldots, n \) (see the beginning of this section).

Let \( S \) be a subset of \( S^{n-1} \). As we already noted before, the main obstacle in using the standard \( \varepsilon \)-net argument to get a lower estimate for \( \inf_{y \in S} \| Ay + By \| \) is the need to control the norm of the matrix \( A + B \) which is not possible unless we impose strong restrictions on its entries. Proposition \( 5 \) provides a workaround: we represent \( A + B \) as a sum of two random matrices, “regular” and “irregular”, satisfying certain conditions, so that the lower bound for \( \inf_{y \in S} \| Ay + By \| \) involves the norm of only the “regular” matrix. The splitting shall be defined with help of the above concept of \( H \)-part. Namely, for some specially chosen \( \lambda \in \mathbb{R} \) and \( H \subset \mathbb{R} \) we define the “regular” part as \( (A - \lambda 1_{n \times n})_H \) and the “irregular” as \( A + B - (A - \lambda 1_{n \times n})_H \) (which is identical to \( (A - \lambda 1_{n \times n})_{\overline{H}} + B + \lambda 1_{n \times n} \)). The set \( H \) shall be bounded which implies boundedness of the entries of \( (A - \lambda 1_{n \times n})_H \). This, together with the appropriately chosen “shift” \( \lambda \), allows us to easily control \( \|(A - \lambda 1_{n \times n})_H\| \) from above. We will define \( H \) as the union of two specially constructed closed intervals on \( \mathbb{R} \). The choice of \( H \) depends on the set \( S \) and may depend on the characteristics of the distribution of the entries of \( A \) (we leave this problem for the last section).

The crucial property that our set \( H \) shall satisfy is: letting \( \bar{A} = A - \lambda 1_{n \times n} \) and \( \bar{B} = B + \lambda 1_{n \times n} \), for certain finite subset of vectors \( N \subset \mathbb{R}^n \) and a collection of linear subspaces \( \{E_{y'} \subset \mathbb{R}^n\}_{y' \in N} \) (see Proposition \( 3 \)) we have

\[
\inf_{y' \in N} d(\bar{A}_{H y'}, V_{\bar{A}, \bar{B}}(H, E_{y'})) \gtrsim \sqrt{N}
\]

with a large probability. This restriction on \( H \) naturally corresponds to the condition \( 3 \) in Proposition \( 3 \). In practice we shall verify this property of \( H \) by proving that for every vector \( y \in B_2^n \) satisfying certain upper bounds on \( \|y\|_{\infty} \) and lower bounds on \( \|y\| \) and for \( E = \text{span}\{e_j\}_{j \in \text{supp}y} \), the distance \( d(\bar{A}_{H y}, V_{\bar{A}, \bar{B}}(H, E)) \) is large with an overwhelming probability. This condition demands a “rich” structure from \( \bar{A}_H \); consequently, the set \( H \) cannot be very small in diameter. On the other hand, the “upper” restrictions on \( H \)
are dictated by the necessity to control the norm of $\tilde{A}_H$. Thus, we have to find a balance between the two requirements.

In order to estimate the distance between the random vector $\tilde{A}_H y$ and the random subspace $V_{A,B}(H,E)$, we will use Corollary 11. However, since in general $V_{A,B}(H,E)$ is dependent (in probabilistic sense) on $\tilde{A}_H y$, an immediate application of the corollary is not possible; instead, we will combine it with a conditioning argument, which is presented in the next section.

3 The distribution of $d(A_H y, V_{A,B}(H,E))$

Assume that we are given $\delta > 1$, $N, n \in \mathbb{N}$ with $N \geq \delta n$, a random $N \times n$ matrix $A$ with i.i.d. entries, a non-random $N \times n$ matrix $B$ and a Borel subset $H \subset \mathbb{R}$ with $\mathbb{P}\{a_{11} \in H\} > 0$. The purpose of this section is to study the distribution of the distance between a random vector $A_H y$ and the random subspace $V_{A,B}(H,E) = (A+B)(E^\perp) + (A_{\perp}B)(E)$, where $E = \text{span}\{e_j\}_{j \in \text{supp} y}$. We give sufficient conditions on $A$, $H$ and $y$ which guarantee that $d(A_H y, V_{A,B}(H,E))$ is large with a large probability (Proposition 11). Note that generally $A_H y$ and $V_{A,B}(H,E)$ are dependent. In order to overcome this problem, we apply a decoupling argument.

We adopt the following notation: For any subset $W \subset \{1,2,\ldots,N\} \times \{1,2,\ldots,n\}$ let

$$
\Omega_W = \{\omega \in \Omega: a_{ij}(\omega) \in H \text{ for all } (i,j) \in W \text{ and } a_{ij}(\omega) \in \overline{\mathbb{P}} \text{ for all } (i,j) \notin W\}.
$$

Given an event $E \subset \Omega$ with $\mathbb{P}(E) > 0$, we denote by $(E, \Sigma_E, \mathbb{P}_E)$ the probability space where the $\sigma$-algebra $\Sigma_E$ of subsets of $E$ is naturally induced by the $\sigma$-algebra $\Sigma$ on $\Omega$, and $\mathbb{P}_E$ is defined by $\mathbb{P}_E(K) = \mathbb{P}(E^{-1}K)$ ($K \in \Sigma_E$).

**Lemma 8** (Conditional independence). Let $A$, $B$ and $H$ be as above, $y \in \mathbb{R}^n$, $E = \text{span}\{e_j\}_{j \in \text{supp} y}$ and let $W \subset \{1,2,\ldots,N\} \times \{1,2,\ldots,n\}$ be such that $\mathbb{P}(\Omega_W) > 0$. Then the random vector $A_H y$ in $\mathbb{R}^N$ and the random subspace $V_{A,B}(H,E) \subset \mathbb{R}^N$ are conditionally independent given event $\Omega_W$. Moreover, the coordinates of $A_H y$ are conditionally independent given $\Omega_W$.

**Proof.** If $\mathbb{P}\{a_{11} \in \overline{\mathbb{P}}\} = 0$ then the assumption $\mathbb{P}(\Omega_W) > 0$ necessarily implies that $W = \{1,2,\ldots,N\} \times \{1,2,\ldots,n\}$ and $\Omega_W = \Omega$ (up to a set of $\mathbb{P}$-measure zero). At the same time, in this case $V_{A,B}(H,E) = (A+B)(E^\perp) + B(E)$ a.s., hence $V_{A,B}(H,E)$ and $A_H y$ are independent on $\Omega = \Omega_W$, and we get the statement.

Now, assume that $\mathbb{P}\{a_{11} \in \overline{\mathbb{P}}\} \neq 0$. It is enough to check that

the random variables $(a_{ij})_H, (a_{ij})_{\overline{\mathbb{P}}} (1 \leq i \leq N, 1 \leq j \leq n)$ are jointly conditionally independent given $\Omega_W$. \hspace{1cm} (4)

Note that for all $\omega \in \Omega_W$ we have $(a_{ij})_{\overline{\mathbb{P}}} (\omega) = 0$ for $(i,j) \in W$ and $(a_{ij})_H (\omega) = 0$ for $(i,j) \notin W$. Hence, to verify (4) it is sufficient to prove that $nN$ variables

$(a_{ij})_H, (i,j) \in W$; $(a_{ij})_{\overline{\mathbb{P}}}, (i,j) \notin W$
are jointly conditionally independent given \( \Omega_W \). But for \((i,j) \in W\) the \(H\)-part of \(a_{ij}\)

satisfies \((a_{ij})_H = a_{ij}\) everywhere on \(\Omega_W\) and, similarly, for \((i,j) \notin W\), we have \((a_{ij})_{\overline{H}} = a_{ij}\)
everywhere on \(\Omega_W\). Hence, once we verify conditional independence for \(a_{ij}\) \((1 \leq i \leq N, 1 \leq j \leq n)\) given \(\Omega_W\), then we immediately get \(\square\). For any Borel subsets \(K_{ij} \subset \mathbb{R}\) \((1 \leq i \leq N, 1 \leq j \leq n)\) we have

\[
\prod_{(i,j)} \mathbb{P}_{\Omega_W} \{ a_{ij} \in K_{ij} \} = \prod_{(i,j) \in W} (\mathbb{P}(\Omega_W)^{-1}\mathbb{P}\{ \omega \in \Omega_W : a_{ij}(\omega) \in K_{ij} \})
\]

\[
= \prod_{(i,j) \in W} (\mathbb{P}\{ a_{ij} \in H \})^{-1}\mathbb{P}\{ a_{ij} \in H \cap K_{ij} \}) \prod_{(i,j) \notin W} (\mathbb{P}\{ a_{ij} \in \overline{H} \})^{-1}\mathbb{P}\{ a_{ij} \in \overline{H} \cap K_{ij} \})
\]

\[
= \mathbb{P}(\Omega_W)^{-1}\mathbb{P}\{ a_{ij} \in H \cap K_{ij} \} \text{ for all } (i,j) \in W \text{ and } a_{ij} \in \overline{H} \cap K_{ij} \text{ for all } (i,j) \notin W \}
\]

\[
= \mathbb{P}_{\Omega_W} \{ a_{ij} \in K_{ij} : 1 \leq i \leq N, 1 \leq j \leq n \},
\]

so \(a_{ij}\) \((1 \leq i \leq N, 1 \leq j \leq n)\) are conditionally independent given \(\Omega_W\). \(\square\)

Lemma 9 shows that Corollary 8 can be applied to \(A_H y\) and the subspace \(V_{A,B}(H, E)\)

“inside” each \(\Omega_W\). Hence, to give a satisfactory lower estimate for \(d(A_H y, V_{A,B}(H, E))\) on entire \(\Omega\), it is enough to verify that there is a subset \(M \subset \mathbb{R}^{(1,2,...,N)}\times(1,2,...,n)\) such that the \(\mathbb{P}\)-measure of the union of \(\Omega_W\)’s \((W \in M)\) is close to 1 and for each \(W \in M\), the restriction of the vector \(A_H y\) to \(\Omega_W\) has sufficiently “spread” coordinates. Of course, such a set \(M\) may exist only under certain assumptions on \(A, H\) and \(y\). In Lemma 9, we formulate those assumptions using random variables that agree on a part of the probability space and are independent when restricted to the other part of \(\Omega\). Let us remark that, whereas the use of such variables has some advantages (in our opinion), it should not be regarded as a necessary ingredient of the proof.

Let \(\xi, \xi'\) be two random variables such that \(\mathbb{P}\{ \xi \in H \} > 0\). We say that \(\xi, \xi'\) are conditionally i.i.d. given event \{\(\omega \in \Omega : \xi(\omega) \in H\)\} and identical on \{\(\omega \in \Omega : \xi(\omega) \in \overline{H}\)\} if the following is true: setting \(E = \{\omega \in \Omega : \xi(\omega) \in H\}\), the restrictions of \(\xi, \xi'\) to the probability space \((E, \Sigma_E, \mathbb{P}_E)\) are i.i.d. and \(\xi(\omega) = \xi'(\omega)\) for \(\omega \in \Omega \setminus E\). The definition implies that \(\xi'\) has the same individual distribution (on \(\Omega\)) as \(\xi\) and for any Borel subsets \(K, K' \subset \mathbb{R}\)

\[
\mathbb{P}\{(\xi, \xi') \in K \times K'\} = \frac{\mathbb{P}\{\xi \in H \cap K\}\mathbb{P}\{\xi \in H \cap K'\}}{\mathbb{P}\{\xi \in H\}} + \mathbb{P}\{\xi \in \overline{H} \cap K \cap K'\};
\]

in particular, \(\mathbb{P}\{(\xi, \xi') \in H \times \overline{H}\} = \mathbb{P}\{(\xi, \xi') \in \overline{H} \times H\} = 0\). Note that \(\xi_\overline{H}\) and \(\xi'_\overline{H}\) are equal a.s. on \(\Omega\). It is a trivial observation that \(\xi_H - \xi'_H\) is symmetrically distributed.

For any event \(E \subset \Omega\) with \(\mathbb{P}(E) > 0\) and any random variable \(\xi\) on \(\Omega\), let \(Q_E(\xi, \cdot)\) be the concentration function of the restriction of \(\xi\) to the probability space \((E, \Sigma_E, \mathbb{P}_E)\).

**Lemma 9.** Let \(H\) be a Borel subset of \(\mathbb{R}\); \(N \geq \delta n\) for some \(\delta > 1\) and let \(A = (a_{ij})\) be an \(N \times n\) random matrix with i.i.d. entries and \(\mathbb{P}\{a_{11} \in H\} > 0\). Further, let \(A' = (a'_{ij})\) be an \(N \times n\) random matrix having the same distribution as \(A\) such that 2-dimensional vectors
\( (a_{ij}, a'_{ij}) \ (1 \leq i \leq N, 1 \leq j \leq n) \) are i.i.d. and for any admissible \( i \) and \( j \) the variables \( a_{ij} \) and \( a'_{ij} \) are conditionally i.i.d. given event \( \{ \omega \in \Omega : a_{ij}(\omega) \in H \} \) and identical on \( \{ \omega \in \Omega : a_{ij}(\omega) \in \overline{\mathcal{T}} \} \). Let \( y = (y_1, y_2, \ldots, y_n) \in \mathbb{R}^n \) and \( s > 0 \) be such that

\[
\mathbb{P}\left\{ \left| \sum_{j=1}^{n} (a_{ij})_H - (a'_{ij})_H \right| y_j > s \right\} \geq \delta^{-1/4}, \quad i = 1, 2, \ldots, N. \tag{5}
\]

Define \( M \) as the collection of all subsets \( W \subset \{1, 2, \ldots, N\} \times \{1, 2, \ldots, n\} \) satisfying

\[
\mathbb{P}(\Omega_W) > 0 \quad \text{and} \quad \left| \left\{ i \in \{1, 2, \ldots, N\} : Q_{\Omega_W} \left( \sum_{j=1}^{n} (a_{ij})_H y_j, \frac{s}{2} \right) \leq 1 - \tau \right\} \right| \geq N\delta^{-1/2}
\]

with \( \tau = \frac{1}{2}(\delta^{-1/4} - \delta^{-1/3}) \). Then

\[
\mathbb{P}\left( \bigcup_{W \in M} \Omega_W \right) \geq 1 - \exp(-w \mathbb{E}) N,
\]

where \( w \mathbb{E} > 0 \) depends only on \( \delta \).

**Proof.** For each \( i = 1, 2, \ldots, N \) and \( J \subset \{1, 2, \ldots, n\} \) let

\[
\Omega^i_J = \{ \omega \in \Omega : a_{ij}(\omega) \in H \quad \text{for all} \quad j \in J \quad \text{and} \quad a_{ij}(\omega) \in \overline{\mathcal{T}} \quad \text{for all} \quad j \notin J \},
\]

and for \( i = 1, 2, \ldots, N \) define

\[
L_i = \left\{ J \subset \{1, 2, \ldots, n\} : \mathbb{P}(\Omega^i_J) > 0 \quad \text{and} \quad Q_{\Omega^i_J} \left( \sum_{j=1}^{n} (a_{ij})_H y_j, \frac{s}{2} \right) \leq 1 - \tau \right\}; \quad \mathcal{E}_i = \bigcup_{J \in L_i} \Omega^i_J.
\]

It is not difficult to see that the events \( \mathcal{E}_i \subset \Omega \ (i = 1, 2, \ldots, N) \) are independent in view of independence of the entries of \( A \).

Fix for a moment any \( i \in \{1, 2, \ldots, N\} \). One can verify that for any \( j \in \{1, 2, \ldots, n\} \) and \( J \subset \{1, 2, \ldots, n\} \) the variables \( (a_{ij})_H \) and \( (a'_{ij})_H \) are i.i.d. given event \( \Omega^i_J \). It follows that

\[
\sum_{j=1}^{n} (a_{ij})_H y_j \quad \text{and} \quad \sum_{j=1}^{n} (a'_{ij})_H y_j \quad \text{are i.i.d. given} \quad \Omega^i_J, \quad \text{for all} \quad J \subset \{1, 2, \ldots, n\}. \tag{6}
\]

Take any subset \( J \subset \{1, 2, \ldots, n\} \) satisfying

\[
\mathbb{P}(\Omega^i_J) > 0 \quad \text{and} \quad \mathbb{P}_{\Omega^i_J} \left\{ \left| \sum_{j=1}^{n} (a_{ij})_H - (a'_{ij})_H \right| y_j > s \right\} \geq 2\tau. \tag{7}
\]
For all \( \lambda \in \mathbb{R} \) we have, in view of (3),
\[
\mathbb{P}_{\Omega'_j} \left\{ \lambda - \frac{s}{2} \leq \sum_{j=1}^{n} (a_{ij})_H y_j \leq \lambda + \frac{s}{2} \right\}^2
\]
\[
= \mathbb{P}_{\Omega'_j} \left\{ \lambda - \frac{s}{2} \leq \sum_{j=1}^{n} (a_{ij})_H y_j \leq \lambda + \frac{s}{2} \right\} \mathbb{P}_{\Omega'_j} \left\{ \lambda - \frac{s}{2} \leq \sum_{j=1}^{n} (a'_{ij})_H y_j \leq \lambda + \frac{s}{2} \right\}
\]
\[
\leq \mathbb{P}_{\Omega'_j} \left\{ \sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j \leq s \right\}
\]
\[
\leq 1 - 2\tau,
\]
implying
\[
Q_{\Omega'_j} \left( \sum_{j=1}^{n} (a_{ij})_H y_j, \frac{s}{2} \right) \leq \sqrt{1 - 2\tau} \leq 1 - \tau.
\]
Thus, any \( J \) satisfying (7) belongs to \( L_i \). Clearly,
\[
\mathbb{P}\left\{ \left| \sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j \right| > s \right\} = \sum_{J} \mathbb{P}_{\Omega'_j} \left\{ \left| \sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j \right| > s \right\} \mathbb{P}(\Omega'_j),
\]
where the summation is taken over \( J \subset \{1, 2, \ldots, n\} \) satisfying \( \mathbb{P}(\Omega'_j) > 0 \). Hence, in view of (5) and the above observations we get
\[
\delta^{-1/4} \leq \sum_{J \in L_i} \mathbb{P}_{\Omega'_j} \left\{ \left| \sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j \right| > s \right\} \mathbb{P}(\Omega'_j)
\]
\[
\leq \sum_{J \in L_i} \mathbb{P}(\Omega'_j) + 2\tau \sum_{J \notin L_i} \mathbb{P}(\Omega'_j)
\]
\[
\leq 2\tau + \mathbb{P}(\mathcal{E}_i),
\]
implying \( \mathbb{P}(\mathcal{E}_i) \geq \delta^{-1/3} \).

We have shown that the events \( \mathcal{E}_i \) \( (i = 1, 2, \ldots, N) \) are independent and \( \mathbb{P}(\mathcal{E}_i) \geq \delta^{-1/3} \) for each \( i \). Now, setting
\[
\mathcal{E} = \{ \omega \in \Omega : \left| \{i \in \{1, 2, \ldots, N\} : \omega \in \mathcal{E}_i \} \right| \geq N\delta^{-1/2} \},
\]
we obtain by Bernstein’s (or Hoeffding’s) inequality \( \mathbb{P}(\mathcal{E}) \geq 1 - \exp(-u\mathbb{E}N) \), where \( u \mathbb{E} > 0 \) depends only on \( \delta \). Take any \( W \subset \{1, 2, \ldots, N\} \times \{1, 2, \ldots, n\} \) such that \( \mathbb{P}(\mathcal{E} \cap \Omega_W) > 0 \). Then, by the construction of \( \mathcal{E} \), there is a subset \( I \subset \{1, 2, \ldots, N\} \) of cardinality at least \( N\delta^{-1/2} \) and sets \( J_i \subset L_i \) \( (i \in I) \) such that \( \Omega_W \subset \Omega_{J_i} \) for all \( i \in I \). For every \( i \in I \) by the definition of \( L_i \) we have
\[
Q_{\Omega_{J_i}} \left( \sum_{j=1}^{n} (a_{ij})_H y_j, \frac{s}{2} \right) \leq 1 - \tau,
\]
hence \( W \subset M \). The argument implies \( \mathcal{E} \subset \bigcup_{W \in M} \Omega_W \) and the result follows.
Next, we combine the result of Lemma 9 with Corollary 6.

**Lemma 10.** Let $N, n, \delta, H, A$, $A'$, $y$ and $s$ be exactly as in Lemma 9 and $B$ be a non-random $N \times n$ matrix. Then

$$\mathbb{P}\{d(A_Hy, V_{A,B}(H, E)) \leq s\sqrt[10]{N}\} \leq 2\exp(-w_{10}N),$$

where $E = \text{span}\{e_j\}_{j \in \text{supp}}$ and $h_{10} > 0$, $w_{10} > 0$ depend only on $\delta$.

**Proof.** Let $M$ and $\tau$ be defined as in Lemma 9 and take any $W \in M$. Let

$$m = \left| \left\{ i \in \{1, 2, \ldots, N\} : Q_{\Omega_W} \left( \sum_{j=1}^{n} (a_{ij})_H y_j, \frac{s}{2} \right) \leq 1 - \tau \right\} \right|.$$  

By the definition of $M$, we have $m \geq N\delta^{-1/2} \geq \sqrt{n}$, hence, taking $d = m - n$ and $\ell = 4(C_{10}^{5})^2/\tau$, by Corollary 6 for $\kappa = \delta^{-1/2} - \delta^{-1}$ and any fixed $n$-dimensional subspace $F \subseteq \mathbb{R}^N$ we obtain

$$\mathbb{P}_{\Omega_W} \left\{ d(A_Hy, F) \leq \frac{s}{2\ell} \sqrt{\kappa N} \right\} \leq 2^{-\kappa N/\ell}. $$

By Lemma 8 the subspace $V_{A,B}(H, E) = (A+B')(E^\perp) + (A_{\Sigma} + B')(E)$ and the vector $A_H y$ are conditionally independent given $\Omega_W$, hence the above estimate immediately implies

$$\mathbb{P}_{\Omega_W} \left\{ d(A_Hy, V_{A,B}(H, E)) \leq \frac{s}{2\ell} \sqrt{\kappa N} \right\} \leq 2^{-\kappa N/\ell}. $$

Since the relation holds for all $W \in M$, in view of Lemma 9 we obtain

$$\mathbb{P} \left\{ d(A_Hy, V_{A,B}(H, E)) \leq \frac{s}{2\ell} \sqrt{\kappa N} \right\} \leq 2^{-\kappa N/\ell} \mathbb{P} \left( \bigcup_{W \in M} \Omega_W \right) + 1 - \mathbb{P} \left( \bigcup_{W \in M} \Omega_W \right)$$

$$\leq 2^{-\kappa N/\ell} + \exp(-w_{10}N),$$

and the result follows. \hfill $\square$

Finally, we can prove the main result of the section:

**Proposition 11.** Let $\delta > 1$, $n, N \in \mathbb{N}$, $N \geq \delta n$ and let $A = (a_{ij})$ be an $N \times n$ random matrix with i.i.d. entries and $B$ be any non-random $N \times n$ matrix. Further, for some $d, r > 0$ let $H$ be a Borel subset of $\mathbb{R}$ such that $H = H_1 \cup H_2$ for disjoint Borel sets $H_1, H_2$ with $d(H_1, H_2) \geq d$ and $\min(\mathbb{P}\{a_{11} \in H_1\}, \mathbb{P}\{a_{11} \in H_2\}) \geq r$. For arbitrary $t > 0$ define

$$l_{11} = \frac{1 - \delta^{-1/4}}{C_{10}} \sqrt{\frac{r}{8} t d}$$

and let $y \in \mathbb{R}^n$ be a vector satisfying $\|y\| \geq t$, $\|y\|_{\infty} \leq \frac{2l_{11}}{d}$ and $E = \text{span}\{e_j\}_{j \in \text{supp}}$. Then

$$\mathbb{P}\{d(A_Hy, V_{A,B}(H, E)) \leq l_{11} \sqrt{N}\} \leq 2\exp(-w_{10}N).$$

13
Proof. Let $A' = (a'_{ij})$ be an $N \times n$ random matrix having the same distribution as $A$ such that 2-dimensional vectors $(a_{ij}, a'_{ij})$ ($1 \leq i \leq N, 1 \leq j \leq n$) are i.i.d. and for any admissible $i$ and $j$ the variables $a_{ij}$ and $a'_{ij}$ are conditionally i.i.d. given event $\{\omega \in \Omega : a_{ij}(\omega) \in H\}$ and identical on $\{\omega \in \Omega : a_{ij}(\omega) \in \overline{H}\}$. For every $i = 1, 2, \ldots, N$ and $j = 1, 2, \ldots, n$, by the formula for the joint distribution of $a_{ij}$ and $a'_{ij}$ we get
\[
P\{|(a_{ij})_H - (a'_{ij})_H| \geq d\} \geq P\{a_{ij} \in H_1 \text{ and } a'_{ij} \in H_2\} + P\{a_{ij} \in H_2 \text{ and } a'_{ij} \in H_1\} \geq r,
\]
hence, in view of symmetric distribution of $(a_{ij})_H - (a'_{ij})_H$, we have $Q((a_{ij})_H - (a'_{ij})_H, \frac{d}{2}) \leq 1 - \frac{r}{2}$. Clearly, $h_{\overline{11}} \geq \frac{d|h_j|}{2}$ for every coordinate $y_j$ of the vector $y$, hence by Theorem 6 for all $i = 1, 2, \ldots, N$
\[
P\left\{\left|\sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j \right| \leq h_{\overline{11}}\right\}
\leq Q\left(\sum_{j=1}^{n} ((a_{ij})_H - (a'_{ij})_H) y_j, h_{\overline{11}}\right)
\leq C_{\overline{11}} h_{\overline{11}} \left(\frac{1}{4} \sum_{j=1}^{n} (1 - Q(\{(a_{ij})_H - (a'_{ij})_H) y_j, \frac{|y_j| d}{2}\)) (y_j d)^2\right)^{-1/2}
\leq C_{\overline{11}} h_{\overline{11}} \left(\frac{8}{8} \sum_{j=1}^{n} (y_j d)^2\right)^{-1/2}
\leq C_{\overline{11}} h_{\overline{11}} \sqrt{\frac{8}{r}} = 1 - \delta^{-1/4}.
\]
Thus, vector $y$ satisfies condition 5 with $s := h_{\overline{11}}$. Then, by Lemma 10
\[
P\{d(A_H y, V_{A,B}(H, E)) \leq h_{\overline{11}} \sqrt{N}\} \leq 2 \exp(-w_{\overline{10}} N).
\]

4 Decomposition of $S^{n-1}$ and proof of Theorem 1

Recall that in Section 2 we defined $S^{n-1}_{\theta}$ as the set of $\theta$-peaky vectors, that is, unit vectors in $\mathbb{R}^n$ whose $l^\infty$-norm is at least $\theta$. We say that a vector $y \in S^{n-1}$ is $m$-sparse if $|\text{supp} y| \leq m$. Next, $y \in S^{n-1}$ is almost $m$-sparse, if there is a subset $J \subset \{1, 2, \ldots, n\}$ of cardinality at most $m$, such that $\|y_{\mathcal{J}}\| \geq 1/2$. The set of all almost $m$-sparse vectors shall be denoted by $S^{n-1}_{m}$. In our proof of Theorem 1 we represent $S^{n-1}$ as the union of three subsets:
\[
S^{n-1} = S^{n-1}_{\theta} \cup (S^{n-1}_{\theta}(\sqrt{N}) \setminus S^{n-1}_{\theta}) \cup (S^{n-1} \setminus S^{n-1}_{\theta}(\sqrt{N}))
\]
where $\theta$ is a function of the parameters $\beta$ and $\delta$ of the theorem. Then the smallest singular value of $A + B$ can be estimated by bounding separately $\inf_y \|Ay + By\|$ over each of the three subsets.

14
The reasons for such a representation of $S^{n-1}$ are purely technical: Proposition 11 proved in the previous section handles vectors with a sufficiently small $\ell_\infty^n$-norm, so instead we use Proposition 7 to deal with the set $S^{n-1}_p(\theta)$. Further, the separate treatment of almost $\sqrt{N}$-sparse vectors is convenient because, on the one hand, the construction of the set $H$ corresponding to $S^{n-1}_a(\sqrt{N}) \setminus S^{n-1}_p(\theta)$ is trivial compared to $S^{n-1}_a(\sqrt{N}) \setminus S^{n-1}_p(\sqrt{N})$; on the other hand, vectors from $S^{n-1}_a(\sqrt{N}) \setminus S^{n-1}_p(\sqrt{N})$ have a useful geometric property (Lemma 16) which the almost sparse vectors generally do not possess. We note that the set $S^{n-1}_a(\sqrt{N})$ in the covering of $S^{n-1}$ can be replaced with $S^{n-1}_a(N^{\kappa})$ for any constant power $\kappa \in (0, 1)$; this would only affect the constants in the final estimate.

In our representation of $S^{n-1}$, we follow an idea from [7], where the unit sphere was split into sets of “close to sparse” and “far from sparse” vectors. A similar splitting was also employed in [13], [14], where the terms “compressible” and “incompressible” were used instead. On the other hand, our “borderline” $\sqrt{N}$ is smaller by the order of magnitude than in the mentioned papers.

The next elementary lemma shall be used in conjunction with Proposition 3.

**Lemma 12.** There is a universal constant $C(12) > 0$ with the following property: Let $n, m \in \mathbb{N}$ with $m \leq n$, $\varepsilon \in (0, 1]$, $S \subset S^{n-1}$ and let $T \subset B_2^n$ be a subset of $m$-sparse vectors satisfying

$$\text{for any } y \in S \text{ there is } x = x(y) \in T \text{ with } y_{\supp y} = x. \tag{8}$$

Then there is a finite set $\mathcal{N} \subset T$ of cardinality at most $(\frac{C(12)}{\varepsilon m})^m$ such that for any $y \in S$ there is $y' = y'(y) \in \mathcal{N}$ with $\|y_{\supp y'} - y'\| \leq \varepsilon$.

**Proof.** For any $J \subset \{1, 2, \ldots, n\}$ with $|J| \leq m$, let $\mathcal{N}_J$ be an $\varepsilon$-net for $T \cap \text{span}\{e_i\}_{i \in J}$ of cardinality at most $(\frac{3}{\varepsilon})^m$. Define $\mathcal{N}$ as the union of $\mathcal{N}_J$ for all admissible $J$. Then, obviously,

$$|\mathcal{N}| \leq 2^m \left(\frac{n}{m}\right)^m \left(\frac{3}{\varepsilon}\right)^m \leq \left(\frac{6ne}{\varepsilon m}\right)^m.$$

Next, fix any $y \in S$ and let $x \in T$ be such that $y_{\supp y} = x$. Since $|\supp y| \leq m$, there is $y' \in \mathcal{N}_{\supp y} \subset \mathcal{N}$ with $\|x - y'\| \leq \varepsilon$. It remains to note that since $\supp y' \subset \supp y$, necessarily $\|y_{\supp y'} - y'\| \leq \|y_{\supp y} - y'\| = \|x - y'\| \leq \varepsilon$. \hfill $\square$

**Proposition 13** (Vectors from $S^{n-1}_a(\sqrt{N})$ with a small $\ell_\infty^n$-norm). For any $\gamma > 0$ and $\delta > 1$ there are $N_{13} \in \mathbb{N}$ and $h_{13} > 0$ depending only on $\gamma$ and $\delta$ with the following property: Let

$$N \geq \max(N_{13}, \delta n), z \in \mathbb{R} \text{ and let } A \text{ be an } N \times n \text{ random matrix with i.i.d. entries such that}
\min(\mathbb{P}\{z - \sqrt{N} \leq a_{11} \leq z - 1\}, \mathbb{P}\{z + 1 \leq a_{11} \leq z + \sqrt{N}\}) \geq \gamma.
\text{Then for the set } S = S^{n-1}_a(\sqrt{N}) \setminus S^{n-1}_p(\theta_{13}), \text{ and any non-random } N \times n \text{ matrix } B
\mathbb{P}\{\inf_{y \in S} \|Ay + By\| \leq h_{13} \sqrt{N}\} \leq \exp(-u_{10} N/2).$$
Proof. Fix any $\gamma > 0$ and $\delta > 1$ and define $d := 2, r := \gamma, t := \frac{1}{2}$; let $h_0$ be as in Proposition 11 and $N_{13} = N_{13}(\gamma, \delta)$ be the smallest integer greater than $\frac{1}{2}$ such that for all $N \geq N_{13}$

$$2(\sqrt{\frac{12}{5}}N)^{3\sqrt{N}} \leq \exp(\frac{u}{10}N/2).$$

Now, take any $n \in N$ and $N \geq \max(N_{13}, 2n)$; let $z$ and $A$ satisfy conditions of the lemma and $B$ be any non-random $N \times n$ matrix. We will assume that $S$ is non-empty. Without loss of generality, $z = 0$ (otherwise, we replace $A, B$ with $A - z1_{N \times n}, B + z1_{N \times n}$). Define $H_1 = [-\sqrt{N}, -1], H_2 = [1, \sqrt{N}], H = H_1 \cup H_2$. Obviously, $d(H_1, H_2) = d$ and $\min(\mathbb{P}\{a_{11} \in H_1\}, \mathbb{P}\{a_{11} \in H_2\}) \geq r$. Let $T \subset B^n_2$ be the set of $\sqrt{N}$-sparse vectors with the Euclidean norm at least $\frac{1}{2}$ and the maximal norm at most $6^2$. Clearly, $T$ and $S$ satisfy (8), hence, by Lemma 12 there is a finite subset $N \subset T$ of cardinality at most $(\sqrt{\frac{12}{5}}N)^{3\sqrt{N}}$ such that for any $y \in S$ there is $y' = y'(y) \in N$ with $\|y_{\text{suppy}'} - y'\| \leq N^{-2}$.

Let $E_{y'} = \text{span}\{e_j\}_{j \in \text{suppy}'\}$ ($y' \in N$) and define an event

$$\mathcal{E} = \{\omega \in \Omega : d(A_H(\omega), y', V_{A,B}(H, E_{y'})(\omega)) > h_0\sqrt{\frac{1}{10}}N \text{ for all } y' \in N\}.$$ 

In view of Proposition 11 the upper estimate for $|N|$ and the definition of $N_{13}$

$$\mathbb{P}(\mathcal{E}) \geq 1 - 2|N| \exp(-\frac{u}{10}N) \geq 1 - \exp(-\frac{u}{10}N/2).$$

Take any $\omega \in \mathcal{E}$ and define $D_1 = A_H(\omega), D_2 = A_{\text{flat}}(\omega) + B, D = D_1 + D_2$. Since all entries of $D_1$ are bounded by $\sqrt{N}$ by absolute value, we get $\|D_1\| \leq N^{3/2}$; next, for every $y' \in N$

$$d(D_1y', D(E_{y'}\perp) + D_2(E_{y'})) > h_0\sqrt{\frac{1}{10}}N$$

(note that $D(E_{y'}\perp) + D_2(E_{y'}) = V_{A,B}(H, E_{y'})(\omega)$). Hence, by Proposition 3 we get

$$\inf_{y' \in S} \|Dy\| > h_0\sqrt{\frac{1}{10}}N - N^{-1/2} \geq \frac{1}{2}h_0\sqrt{\frac{1}{10}}N.$$

Finally, applying the above argument to all $\omega \in \mathcal{E}$, we get the result. \hfill \Box

As we noted before, construction of the set $H$ corresponding to $S^{n-1} \setminus S_{a}^{n-1}(\sqrt{N})$ is not so trivial as in the case of almost $\sqrt{N}$-sparse vectors. The reason is that in general the set $S^{n-1} \setminus S_{a}^{n-1}(\sqrt{N})$ is much larger than $S_{a}^{n-1}(\sqrt{N})$, and we have to apply more delicate arguments to get a satisfactory probabilistic estimate. The construction of $H$ for the set of “far from $\sqrt{N}$-sparse” vectors is contained in the following lemma:

**Lemma 14.** Let $\xi$ be a random variable such that for some $z \in \mathbb{R}, \gamma > 0, N \in \mathbb{N}$ we have

$$\min(\mathbb{P}\{z - \sqrt{N} \leq \xi \leq z - 1\}, \mathbb{P}\{z + 1 \leq \xi \leq z + \sqrt{N}\}) \geq \gamma.$$ 

Then there exists an integer $\ell \in [0, \lfloor \log_2 \sqrt{N} \rfloor], \lambda \in \mathbb{R}$ and disjoint Borel sets $H_1, H_2 \subset [-2^{\ell+2}, 2^{\ell+2}]$ such that $d(H_1, H_2) \geq 2^{\ell}, \min(\mathbb{P}\{\xi - \lambda \in H_1\}, \mathbb{P}\{\xi - \lambda \in H_2\}) \geq \gamma \sqrt{2^{-\ell/8}}$ and $\mathbb{E}(\xi - \lambda)_H = 0$ for $H = H_1 \cup H_2$ and a universal constant $c_{14} > 0$. 

16
Proof. Without loss of generality we can assume that $z = 0$. Let \[ m = \left( \sum_{m=0}^{\infty} 2^{-m/8} \right)^{-1}. \]

Then, by the conditions on $\xi$, there are $\ell_1, \ell_2 \in \{0, 1, \ldots, \lfloor \log_2 \sqrt{N} \rfloor \}$ such that \[
\mathbb{P}\{ \xi \in [-2^{\ell_1+1}, -2^{\ell_1}] \} \geq (\frac{1}{14}) 2^{-\ell_1/8}, \quad \mathbb{P}\{ \xi \in [2^{\ell_2}, 2^{\ell_2+1}] \} \geq (\frac{1}{14}) 2^{-\ell_2/8}.
\]

Now, define $\lambda$ as the conditional expectation of $\xi$ given the event $\mathcal{M} = \{ \omega \in \Omega : \xi(\omega) \in [-2^{\ell_1+1}, -2^{\ell_1}] \cup [2^{\ell_2}, 2^{\ell_2+1}] \}$, i.e.

\[
\lambda = \mathbb{P}(\mathcal{M})^{-1} \int_{\mathcal{M}} \xi(\omega) d\omega.
\]

Let $H_1 = -\lambda + [-2^{\ell_1+1}, -2^{\ell_1}]$ and $H_2 = -\lambda + [2^{\ell_2}, 2^{\ell_2+1}]$. Note that necessarily $\lambda \in [-2^{\ell_1+1}, 2^{\ell_2+1}]$, hence $H_1, H_2 \subset [-2^{\ell_2+2}, 2^{\ell_2+2}]$ for $\ell = \max(\ell_1, \ell_2)$. Obviously, $d(H_1, H_2) \geq 2^{\ell}$ and for $H = H_1 \cup H_2$

\[
\mathbb{E}(\xi - \lambda)_H = \int_{\{\xi(\omega) - \lambda \in H\}} (\xi(\omega) - \lambda) d\omega = \int_{\mathcal{M}} (\xi(\omega) - \lambda) d\omega = 0.
\]

Finally,

\[
\min\{ \mathbb{P}\{ \xi - \lambda \in H_1 \}, \mathbb{P}\{ \xi - \lambda \in H_2 \} \} = \min\{ \mathbb{P}\{ \xi \in [-2^{\ell_1+1}, -2^{\ell_1}] \}, \mathbb{P}\{ \xi \in [2^{\ell_2}, 2^{\ell_2+1}] \} \} \geq (\frac{1}{14}) 2^{-\ell/8}.
\]

\[ \square \]

Let us recall a folklore estimate of the norm of a random matrix with bounded mean zero entries (see, for example, [11 Proposition 2.4]):

**Lemma 15.** Let $W = (w_{ij})$ be an $N \times n$ ($N \geq n$) random matrix with i.i.d. mean zero entries; $R > 0$ and assume that $|w_{ij}| \leq R$ a.s. Then for a universal constant $C_{15} > 0$

\[
\mathbb{P}\{ \|W\| \geq C_{15} R \sqrt{N} \} \leq \exp(-N).
\]

The next lemma highlights a useful property of the vectors from $S_{n-1}^{n-1}(\sqrt{N})$:

**Lemma 16.** For any integer $N \geq n \geq m \geq 1$ and any $y \in S_{n-1}^{n-1}(\sqrt{N})$ there is a set $J = J(y) \subset \{1, 2, \ldots, n\}$ such that $|J| \leq m$, $\|y_{\mathcal{J}}\| \geq \frac{1}{2} \sqrt{\frac{m}{n}}$ and $\|y_{\Delta J}\|_{\infty} \leq \frac{1}{\lfloor N^{1/4} \rfloor}$.

**Proof.** Take any $N \geq n \geq m \geq 1$ and $y = (y_1, y_2, \ldots, y_n) \in S_{n-1}^{n-1}(\sqrt{N})$ and let

\[
J'(y) = \left\{ j \in \{1, 2, \ldots, n\} : |y_j| \leq \frac{1}{\lfloor N^{1/4} \rfloor} \right\}.
\]

Obviously, $|J'| \geq n - \sqrt{N} > 0$ and, since $y$ is not almost $\sqrt{N}$-sparse, $\|y_{\mathcal{J}'}\| \geq \sqrt{3/4}$. Let $\{J'_1, J'_2, \ldots, J'_{p}\}$ be any partition of $J'$ into pairwise disjoint subsets of cardinality at most $m$ with $p \leq \lceil n/m \rceil$. Then, clearly, for some $q \in \{1, 2, \ldots, p\}$, $\|y_{\mathcal{J}_q}\| \geq \|y_{\mathcal{J}'}\|/\sqrt{p} > \frac{1}{2} \sqrt{\frac{m}{n}}$. Setting, $J(y) = J_q$, we get the result. \[ \square \]
Proposition 17 (The set $S^{n-1}/S_{a}^{n-1}(\sqrt{N})$). For any $\gamma > 0, \delta > 1$ there are $N \in \mathbb{N}$ and $l \in \mathbb{N}$ depending only on $\gamma$ and $\delta$ with the following property: Let $N \geq \max(N, \delta n)$ and let $A$ be an $N \times n$ random matrix with i.i.d. entries such that

$$\min(\mathbb{P}\{z - \sqrt{N} \leq a_{11} \leq z - 1\}, \mathbb{P}\{z + 1 \leq a_{11} \leq z + \sqrt{N}\}) \geq \gamma$$

for some $z \in \mathbb{R}$. Then for any non-random $N \times n$ matrix $B$ and the set $S = S^{n-1}/S_{a}^{n-1}(\sqrt{N})$ we have

$$\mathbb{P}\{\inf_{y \in S} \|Ay + By\| \leq h\} \leq \exp(-w/2).$$

Proof. Fix any $\gamma > 0$ and $\delta > 1$. To make the notation more compact, denote $f_0 := (1 - \delta^{-1/4})\sqrt{17}$ and let $\tau_0 = \tau_0(\gamma, \delta)$ be the largest number in $(0, 1]$ such that for all $s \geq 0$

$$\left(16\sqrt{8C_{17}15^{8/2}2^{-s/4}}\right)^{2-s/4} \leq \exp(u/4)$$

(it is not difficult to see that $\tau_0$ is well defined). Then, take $N = N(\gamma, \delta)$ to be the smallest positive integer such that for all $N \geq N^{17}$

$$\frac{1}{[N^{1/4}]} \leq \frac{f_0\sqrt{\tau_0}}{4N^{3/16}} \quad \text{and} \quad \frac{48\sqrt{8NC_{17}15}}{h_{10}f_0\tau_0} \leq \exp(uN/4).$$

(9)

Let $N \geq N^{17}$, $N \geq \delta n$ and let $A$ be an $N \times n$ random matrix with entries satisfying conditions of the lemma and $B$ be any non-random $N \times n$ matrix.

By Lemma 14 there is an integer $\ell \in [0, \lfloor \log_2(\sqrt{N}) \rfloor]$, $\lambda \in \mathbb{R}$ and disjoint Borel sets $H_1, H_2 \subset [-2^{\ell+2}, 2^{\ell+2}]$ such that $d(H_1, H_2) \geq 2^{\ell} \min(\mathbb{P}\{a_{11} - \lambda \in H_1\}, \mathbb{P}\{a_{11} - \lambda \in H_2\}) \geq 14 \gamma 2^{-\ell/8}$ and $\mathbb{E}(a_{11} - \lambda)_H = 0$ for $H = H_1 \cup H_2$. Denote $\tilde{A} = A - \lambda 1_{N \times n}$, $\tilde{B} = B + \lambda 1_{N \times n}$ and let

$$R := 2^{\ell+2}, \quad d := 2^{\ell}, \quad r := \lfloor \frac{15}{\ell} \rfloor 2^{-\ell/8}, \quad m := \left\lfloor \frac{\tau_0 n}{2^{7/4}} \right\rfloor, \quad t := \frac{1}{2} \sqrt{\frac{m}{n}}, \quad \varepsilon := \frac{\ell}{2C_{17}15} R,$$

where $h_{10}$ is defined as in Proposition 14. Assume that $S$ is non-empty and let $T \subset B_2^n$ consist of all $m$-sparse vectors $y \in B_2^n$ with $\|y\|_1 \geq t$ and $\|y\|_\infty \leq \frac{\ell}{d}$. The first inequality in (9) and a simple calculation show that $\frac{1}{[N^{1/4}]} \leq \frac{2^{1/4}}{d}$. Hence, in view of Lemma 16, $T$ is non-empty and satisfies (8). By Lemma 12 there is a finite subset $N \subset T$ of cardinality at most $\left(\frac{m^{1/4}}{m^{1/4}}\right)^m$ such that for any $y \in S$ there is $y' = y'(y) \in N$ with $\|y_{\text{supp}} y' - y\| \leq \varepsilon$.

For each $y' \in N$ denote $E_{y'} = \text{span}\{e_j\}_{j \in \text{supp} y'}$. By Proposition 11

$$\mathbb{P}\{d(\tilde{A}y', V_{\tilde{A},\tilde{B}}(H, E_{y'})) \leq h\} \leq 2\exp(-wN).$$

Define an event

$$\mathcal{E} = \{\omega \in \Omega : d(\tilde{A}(\omega)y, V_{\tilde{A},\tilde{B}}(H, E_{y'})(\omega)) > h\} \leq \exp(-wN).$$

for all $y' \in N$ and $\|\tilde{A}(\omega)\| \leq C_{17}R\sqrt{N}$. 

18
By the above probability estimates and Lemma \[15\],
\[
\mathbb{P}(\mathcal{E}) \geq 1 - \exp(-N) - 2|\mathcal{N}| \exp(-u_{10}N) \geq 1 - \exp(-N) - 2\left(\frac{12}{m\varepsilon}\right)^m \exp(-u_{10}N).
\]
Using the definition of $\varepsilon$, $m$, $\tau_0$ and the second inequality in (3), we can estimate the probability as
\[
\mathbb{P}(\mathcal{E}) \geq 1 - 3\left(\frac{8C}{\tau_0}\frac{12}{15} \frac{\ell+\ell/4}{\tau_0} \exp(-u_{10}N)
\geq 1 - 3\left(\frac{16\sqrt{C}}{h_{10}/0\tau_0} \frac{\ell/2}{\tau_0} \exp(-u_{10}N)
\geq 1 - \exp(-u_{10}N/2).
\]

Take any $\omega \in \mathcal{E}$ and define $D_1 = \bar{A}H(\omega)$, $D_2 = \bar{A}H(\omega) + \bar{B}$, $D = A(\omega) + B(\omega) = D_1 + D_2$. Then $\|D_1\| \leq C_{13}R\sqrt{N}$ and for every $y' \in \mathcal{N}$ we have
\[
d(D_1y', D(E^1_{y'}) + D_2(E_{y'})) > l_{10}\sqrt{N}.
\]
Hence, by Proposition \[3\] and the definition of $\varepsilon$, we get
\[
\inf_{y \in \mathcal{S}} \|Dy\| > l_{10}\sqrt{N} - \varepsilon C_{13}R\sqrt{N} = \frac{1}{2}\frac{l_{10}}{11} \sqrt{N} \geq \frac{l_{10}}{11} \tau_0 \sqrt{N}.
\]
Finally, applying the above argument to entire set $\mathcal{E}$, we obtain the result.

Proof of Theorem \[4\]. In view of the trivial identity $Q(a_{ij}, \alpha) = Q(a_{ij} / \alpha, 1)$, it is enough to prove the theorem for $\alpha = 1$. Fix any $\delta > 0$ and $\beta > 0$, let $\gamma = \beta/4$ and let $N_0 = N_0(\beta, \delta)$ be the smallest integer such that $N_0 \geq \max(N_{13}, N_{17})$ and for all $N \geq N_0$
\[
N \leq \exp(u_{10}N/2) \quad \text{and} \quad 3 \leq \exp(\min(u_{10}, u_{10})N/4).
\]
Take any $N, n \in \mathbb{N}$ with $N \geq \max(N_0, \delta n)$, let $A = (a_{ij})$ be a $N \times n$ random matrix with i.i.d. entries satisfying $Q(a_{11}, 1) \leq 1 - \beta$ and let $B$ be any non-random $N \times n$ matrix. By the right-continuity of the cdf of $a_{11}$, there is $z \in \mathbb{R}$ such that
\[
\mathbb{P}\{a_{11} \leq z - 1\} \geq \frac{\beta}{2} \quad \text{and} \quad \mathbb{P}\{a_{11} < z - 1\} \leq \frac{\beta}{2}.
\]
Then
\[
\mathbb{P}\{a_{11} \geq z + 1\} \geq 1 - \mathbb{P}\{a_{11} < z - 1\} - Q(a_{11}, 1) \geq \frac{\beta}{2}.
\]
Let us consider three cases.

1) $\mathbb{P}\{z + 1 \leq a_{11} \leq z + \sqrt{N}\} \leq \gamma$. Then $Q(a_{11}, \sqrt{N}/8) \leq Q(a_{11}, (\sqrt{N} - 1)/2) \leq 1 - \gamma$. Obviously, any vector on $S^{n-1}$ is $N^{-1/2}$-peaky. Then, applying Proposition \[4\] with the “scaling factor” $\sqrt{N}/8$, we get
\[
\mathbb{P}\{s_n(A + B) \leq l_{17}\sqrt{N}/8\} = \mathbb{P}\{\inf_{y \in S^{n-1}} \|Ay + By\| \leq l_{17}\sqrt{N}/8\}
\leq n \exp(-u_{17}N)
\leq \exp(-u_{10}N/2).
\]
2) \( P\{z - \sqrt{N} \leq a_{11} \leq z - 1\} \leq \gamma \). Treated as above.

3) \( \min\left(P\{z - \sqrt{N} \leq a_{11} \leq z - 1\}, P\{z + 1 \leq a_{11} \leq z + \sqrt{N}\}\right) \geq \gamma \). Define \( \theta_{13} \) as in Proposition 13. By Proposition 7 for peaky vectors,

\[
P\left\{ \inf_{y \in S^{n-1}} \|Ay + By\| \leq h_{13}\sqrt{N} \right\} \leq n \exp(-u_{13} N) \leq \exp(-u_{13} N/2) .
\]

By Propositions 13 and 17 for \( S = S^{n-1} \setminus S^{(n-1)} \setminus \{13\} \) and \( S' = S^{n-1} \setminus S^{(n-1)} \setminus \{13\} \) we have

\[
P\left\{ \inf_{y \in S} \|Ay + By\| \leq h_{13}\sqrt{N} \right\} \leq \exp(-u_{13} N/2) ;
\]
\[
P\left\{ \inf_{y \in S'} \|Ay + By\| \leq h_{17}\sqrt{N} \right\} \leq \exp(-u_{17} N/2) .
\]

Combining the estimates, we get for \( h = \min(h_{13}, h_{13}, h_{17}) \):

\[
P\left\{ s_n(A + B) \leq h\sqrt{N} \right\} \leq \exp(-u_{13} N/2) + 2 \exp(-u_{17} N/2)
\]
\[
\leq \exp(- \min(u_{13}, u_{17}) N/4) .
\]

This completes the proof. \( \square \)

5 Acknowledgement

I would like to thank my supervisor Prof. N. Tomczak-Jaegermann for valuable suggestions that helped improve structure of the proof.
