(Dated: March 23, 2022)

We discuss a pseudospin representation of the two-dimensional $t$-$J$ model. We introduce pseudospins associated with empty sites, deriving a new representation of the $t$-$J$ model that consists of local spins and spinless fermions. We show, within a mean-field approximation, that our representation of the $t$-$J$ model corresponds to the isotropic antiferromagnetic Heisenberg model in an effective magnetic field. The strength and the direction of the effective field are determined by the hole doping $\delta$ and the orientation of pseudospins associated with empty sites, respectively. We find that the staggered magnetization in the standard representation corresponds to the component of magnetization perpendicular to the effective field in our pseudospin representation. Using a many-body Green’s function method, we show that the staggered magnetization decreases with increasing hole doping and disappears at $\delta \approx 0.06 - 0.15$ for $t/J = 2 - 5$. Our results are in good agreement with experiments and numerical calculations in contradistinction to usual mean-field methods.

I. INTRODUCTION

It is well known that the essential physical properties of the copper oxide materials are described by the two-dimensional $t$-$J$ model. The action of this model is restricted to the single occupancy sector of Hilbert space, $\sum \sigma c_{i\sigma}^\dagger c_{i\sigma} \leq 1$. At half-filling, the $t$-$J$ model reduces to an antiferromagnetic Heisenberg model. In the doped case, on the other hand, due to the single occupancy constraint, electrons can move only onto empty sites. Thus the constrained electron operators no longer obey the fermionic anti-commutation relations.

The slave particle mean-field methods were the first approaches to overcome this problem. In these methods, the constrained electron operators are expressed in terms of auxiliary fermions and bosons. However, as the local single occupancy constraints are replaced by an average global constraint, these mean-field methods lead to considerable errors: for example, the antiferromagnetic long-range order is overestimated.

Another approach is to express the constrained electron operators in terms of spinless fermions and spin-1/2 operators by introducing pseudospins state associated with empty sites. This method is called the pseudospin representation. The spin-“up” and spin-“down” symmetry (time-reversal symmetry) of this representation is discussed by Wang and Rice and Loos. In the present paper, we develop this idea and calculate the critical doping $\delta_c$ where the antiferromagnetic long-range order disappears.

Our representation of the $t$-$J$ model corresponds to the isotropic antiferromagnetic Heisenberg model in an effective magnetic field within a mean-field approximation. In order to calculate the staggered magnetization of the model, we employ the many-body Green’s function method developed by Fröbrich and Kuntz. Unlike the slave particle methods, we show that the critical doping $\delta_c$ for the disappearance of antiferromagnetic long-range order is in good agreement with the numerical calculations.

This paper is organized as follows. In Sec. II we introduce a transformation mapping the original Hilbert space of the constrained electrons to the tensor-product space of the spinless fermion and spin states. We also discuss the difference between our method and the preceding methods. In Sec. III using the many-body Green’s function method, we calculate the staggered magnetization of the model obtained in Sec. II within a mean-field approximation. A summary is presented in Sec. IV.

II. PSEUDOSPIN REPRESENTATION

We consider the $t$-$J$ Hamiltonian

$$H = -t \sum_{<i,j>,\sigma} (c_{i\sigma}^\dagger c_{j\sigma} + \text{h.c.}) - \mu \sum_{i\sigma} c_{i\sigma}^\dagger c_{i\sigma} + J \sum_{<i,j>} s_i \cdot s_j, \quad (1)$$

where $c_{i\sigma}$ is the electron annihilation operator with spin $\sigma$ at site $i$, $\mu$ is the chemical potential, and $s_i = \frac{1}{2} \sum_{\alpha\beta} c_{i\alpha}^\dagger \tau_{\alpha\beta} c_{i\beta}$ is the spin operator with the Pauli matrices $\tau$. The sum is taken over all nearest neighbor bonds. The electron in this model is subjected to the constraint of no double occupancy, i.e.,

$$\sum_{\sigma} c_{i\sigma}^\dagger c_{i\sigma} \leq 1. \quad (2)$$

Consequently, the basis of possible states in the $t$-$J$ model consist of the states $|i\sigma\rangle$ and $|i0\rangle$, which correspond to a site singly occupied by an electron with spin $\sigma$ and to an empty site, respectively. The constrained electron operators $c_{i\sigma}$ act on this basis as

$$c_{i\sigma} |i\sigma\rangle = |i0\rangle, \quad c_{i\sigma}^\dagger |i0\rangle = |i\sigma\rangle. \quad (3)$$
A. Pseudospin associated with empty site

One of the most popular techniques to handle the single occupancy constraint \( \hat{c}_i \) is the slave particle method. In the slave boson representation, the constrained electron operators are given by the mapping \( \hat{c}_i \rightarrow b_i^\dagger f_i \), where \( b_i \) is the bosonic operator annihilating the empty state and \( f_i \) is the fermionic operator annihilating the single occupied state. In this case, the non-holonomic constraint \( \hat{b}_i^\dagger \hat{b}_i + \sum_i f_i^\dagger f_i = 1 \) is replaced by the holonomic constraint \( \hat{b}_i^\dagger \hat{b}_i = 1 \). For practical purposes, however, these local constraints for each site are almost inevitably replaced by an average global constraint, resulting in errors: one of the most serious drawbacks is that the antiferromagnetic long-range order is overestimated.

In this paper, we develop another approach, rewriting the \( t-J \) model in terms of spinless fermionic operators (charge degree of freedom) and local spin-\( \frac{1}{2} \) operators. In this approach, the Hilbert space is mapped onto a tensor product space, \( \mathcal{H}_S \otimes \mathcal{H}_S \). Consequently, the single occupancy constraint

\[
\sum_{\sigma} c_i^\dagger c_i \leq 1 \rightarrow 1 - h_i^\dagger h_i \leq 1
\]

is automatically satisfied. Thus no approximations for the constraint are necessary unlike the slave particle method.

B. Pseudospin representation of \( t-J \) model

In our pseudospin representation, the \( t-J \) model is found to be expressed as

\[
\hat{H} = -t \sum_{<i,j>} \left[ h_i h_j^\dagger \left\{ C_1 S_i^+ S_j^- + C_2 S_i^- S_j^+ \right\} \
+ C_1 S_i^+ S_j^+ S_i^- S_j^- + C_2 S_i^+ S_j^- S_i^- S_j^+ \right] + h.c. \
+ \mu \sum_i h_i^\dagger h_i + J \sum_{<i,j>} h_i^\dagger S_i \cdot S_j h_j^\dagger,
\]

which can be rewritten in the following more convenient form with \( C_1 = \cos \frac{\theta}{2} \) and \( C_2 = \cos \frac{\theta}{2} \) [Fig. 1]:

\[
\hat{H} = -t \sum_{<i,j>} \left[ h_i h_j^\dagger \left\{ S_i \cdot S_j + \frac{1}{4} \right\} \
\right. \
+ n \cdot \left( \frac{1}{2} S_i + \frac{1}{2} S_j + i S_i \times S_j \right) \right] + h.c. \
\left. - \mu \sum_i h_i^\dagger h_i + J \sum_{<i,j>} h_i^\dagger S_i \cdot S_j h_j^\dagger,
\]

where \( n = (\sin \theta \cos \varphi, \sin \theta \sin \varphi, \cos \theta) \) is a unit vector in the orientation of pseudospins. Loosely put a certain restriction on the orientation of the pseudospins so that
the time-reversal symmetry of the $t$-$J$ model is preserved, assuming that the “spin” operators $\mathbf{S}_i$ are transformed in the time-reversal operation similarly to the “true” spin operators $\mathbf{s}_i$. In contrast, we put no restriction on the parameters $\theta$ and $\varphi$. In Sec. III B, we show that our results are independent of the parameters $\theta$ and $\varphi$.

The representation of the $t$-$J$ model introduced in Ref. 11 can be obtained by setting $\theta = 0$ in Eq. [13]. The similar expression is also introduced for the Hubbard model in Ref. 14. For simplicity, in this paper, we also choose the parameters as $\theta = 0$, i.e., the pseudospins are aligned along the $z$ axis. Consequently, the pseudospin representation of the $t$-$J$ model is obtained as

$$
\hat{H} = -t \sum_{<i,j>} \left[ h_i h_j \left\{ \mathbf{S}_i \cdot \mathbf{S}_j + \frac{1}{4} \right\} + \frac{1}{2} S^z_i + \frac{1}{2} S^z_j + i(S_i \times S_j)_z \right] + h.c. \right] 
$$

$$
-\mu \sum_i h_i^\dagger h_i + J \sum_{<i,j>} h_i^\dagger \mathbf{S}_i \cdot \mathbf{S}_j h_j^\dagger,
$$

(14)

Only for “true” spins, the $J$-term in Eq. [14] represents the ordinary magnetic energy. At half-filling, the $t$-$J$ Hamiltonian $\hat{H}$ [Eq. (14)] is reduced to the Heisenberg Hamiltonian.

C. Mean-field approximation

Within the mean-field approximation, the $t$-$J$ Hamiltonian $\hat{H}$ [Eq. (14)] can be decoupled into a holon part, $\hat{H}^{\text{MF}}_h$, and a spin part, $\hat{H}^{\text{MF}}_s$, as

$$
\hat{H}^{\text{MF}}_h = t_{\text{eff}} \sum_{<i,j>} (h_i^\dagger h_j + \text{h.c.}) - \mu \sum_i h_i^\dagger h_i, 
$$

(15)

$$
\hat{H}^{\text{MF}}_s = J_{\text{eff}} \sum_i \mathbf{S}_i \cdot \mathbf{S}_j - B^{\text{eff}}_z \sum_i S^z_i
$$

(16)

with $t_{\text{eff}} = t \langle \mathbf{S}_i \cdot \mathbf{S}_j \rangle + \frac{1}{4} + \frac{1}{2} S^z_i + \frac{1}{2} S^z_j$, $J_{\text{eff}} = J \langle\{1 - \delta^2\} - 2t\phi\rangle + 2t\phi$, and $B^{\text{eff}}_z = -4t\phi$, where $\langle\cdots\rangle$ is an average over the ensemble. The hole doping and the particle-hole order parameter are defined as $\delta = \langle h_i^\dagger h_i \rangle$ and $\phi = \langle h_i^\dagger h_{i+\eta}\rangle$ with $\eta = \pm \hat{x}, \pm \hat{y}$, respectively.

The spin part $\hat{H}^{\text{MF}}_s$ [Eq. (16)] corresponds to the Hamiltonian describing the isotropic antiferromagnet in a uniform magnetic field with the effective exchange constant $J_{\text{eff}}$ and the effective magnetic field $B^{\text{eff}}_z$ along $z$ axis. We note that the direction of the effective field depends on the choice of the orientation of the pseudospin.

III. DOPING DEPENDENCE OF STAGGERED MAGNETIZATION

In this section, we consider the doping dependence of the staggered magnetization of the mean-field Hamiltonian (13) and (16). In Sec. III A, we calculate the components of magnetization for the Heisenberg antiferromagnet

$$
\hat{H} = \sum_{<i,j>} \left( J \mathbf{S}_i \cdot \mathbf{S}_j + D^z S^z_i S^z_j \right) - B^z \sum_i S^z_i,
$$

(17)

where $J$ is the exchange constant, $D^z$ is the anisotropy parameter, and $B^z$ is the magnetic field along $z$ axis. The Heisenberg model (17) corresponds to the spin part of the mean-field Hamiltonian (16) with

$$
J \rightarrow J_{\text{eff}}, \quad D^z \rightarrow 0, \quad B^z \rightarrow B^{\text{eff}}_z.
$$

(18)

Using this correspondence, we calculate the staggered magnetization of the mean-field Hamiltonian (13) and (16) in Sec. III B.

A. Antiferromagnet in a magnetic field

The magnetic properties of two-dimensional antiferromagnets have been the focus of many preceding theoretical studies. In particular, the properties of a two-dimensional anisotropic antiferromagnet in a transverse field were recently studied with rotating frame methods and in the non-rotating frame, of which differences were discussed by Fröblich and Kunitz. In this subsection, we calculate the components of magnetization of the Heisenberg model (17) directly in the non-rotating frame as in Ref. 15. The retarded Green’s functions are defined as

$$
G^{\alpha\beta}_{ij}(t - t') = -i \theta(t - t') \langle \langle \mathbf{S}^{\alpha}_{i}(t), \mathbf{S}^{\beta}_{j}(t') \rangle \rangle
$$

$$
= \langle \langle \mathbf{S}^{\alpha}_{i}, \mathbf{S}^{\beta}_{j} \rangle \rangle ; \quad \alpha = +, -, z , \quad (19)
$$

where $\theta(t)$ is the step function. The Fourier transform of the Green’s functions are denoted by $\langle \langle \mathbf{S}^{\alpha}_{i}, \mathbf{S}^{\beta}_{j} \rangle \rangle_\omega$ in the energy space. The equations of motion for the Green’s functions given as Eq. [19] are expressed as

$$
\omega G^{\alpha\beta}_{ij}(\omega) = \left( \begin{array}{cc}
2 \langle \langle S^z_i \rangle \delta_{ij} & 0 \\
0 & -\langle \langle S^z_i \rangle \delta_{ij} \end{array} \right) + \langle \langle \mathbf{S}^{\alpha}_{i}, \hat{H}; \mathbf{S}^{\beta}_{j} \rangle \rangle_\omega.
$$

(20)

In order to close the system of equations, we adopt the Tyablikov (RPA)-decoupling method of higher-order Green’s functions:

$$
\langle \langle \mathbf{S}^{\alpha}_{i}, \mathbf{S}^{\beta}_{k} \rangle \rangle_\omega \approx \langle \langle \mathbf{S}^{\alpha}_{i} \rangle \rangle_\omega \langle \langle \mathbf{S}^{\beta}_{k} \rangle \rangle_\omega + \langle \langle \mathbf{S}^{\alpha}_{i}, \hat{H}; \mathbf{S}^{\beta}_{k} \rangle \rangle_\omega.
$$

(21)

Fourier transformations to momentum space are given by

$$
G^{\alpha\beta}_{ij}(\mathbf{q}) = \frac{2}{N} \sum_{\mathbf{k}, \nu, \nu'} G^{\alpha\beta}_{i\nu,j\nu'} e^{-i\mathbf{q} \cdot (\mathbf{R}_{\nu} - \mathbf{R}_{\nu'})},
$$

(22)

where subscripts $\mu$, $\nu$ denote sublattice indices (A or B). Each sublattice consists of $N/2$ lattice sites. Furthermore, to simplify the calculations, we assume that
the magnetic components can be defined as \( \langle S_{ix} \rangle = -\langle S_{ix}^- \rangle \equiv m^z \) and \( \langle S_{iz} \rangle = \langle S_{iz}^- \rangle \equiv m^z \) due to the symmetry of the present case. We now rewrite Eq. (23) in a matrix form,

\[
\left( \omega \mathbb{1} - \begin{pmatrix} \Gamma & 0 \\ 0 & \Gamma \end{pmatrix} \right) \begin{pmatrix} G_A \\ G_B \end{pmatrix} = \begin{pmatrix} A_A \\ A_B \end{pmatrix}. \tag{23}
\]

In Eq. (23), the diagonal 6 x 6 sub-matrix \( \Gamma \) is given by

\[
\Gamma = \begin{pmatrix}
-a & 0 & -b & e_q & d_q & -e_q \\
0 & a & b & -d_q & -e_q & e_q \\
\frac{1}{2}b & 0 & -\frac{1}{2}b & -e_q & 0 & a \\
-e_q & d_q & e_q & -a & 0 & b \\
-d_q & -e_q & -e_q & 0 & a & -b \\
\frac{1}{2}e_q & -\frac{1}{2}e_q & 0 & \frac{1}{2}b & -\frac{1}{2}b & 0
\end{pmatrix}, \tag{24}
\]

with \( a = zJm^2 + B^2, \ b = z(J + D^x)m^2, \ c_q = z(J + \frac{1}{2}D^x)\gamma_qm^2, \ d_q = \frac{1}{2}zD^x\gamma_qm^2, \) and \( e_q = zJ\gamma_qm^2, \) where \( z = 4 \) is the number of nearest neighbors and \( \gamma_q = \frac{1}{2}(\cos q_x + \cos q_y) \) is the Fourier factor for a square lattice: we set the lattice constant to be unity. The sublattice Green’s functions \( G_{\mu} \) are defined as

\[
G_{\mu} = \begin{pmatrix} G_{A\mu} \\ G_{B\mu} \end{pmatrix}; \ \mu = A, B, \tag{25}
\]

with

\[
G_{\mu \nu} = \begin{pmatrix} G_{A\mu \nu} \\ G_{B\mu \nu} \end{pmatrix}; \ \mu, \nu = A, B, \tag{26}
\]

while the vectors \( A_{\mu} \) are given by

\[
A_{\mu} = \begin{pmatrix} A_{A\mu} \delta_{A\mu} \\ A_{B\mu} \delta_{B\mu} \end{pmatrix}; \ \mu = A, B, \tag{27}
\]

with

\[
A_{\mu \nu} = \begin{pmatrix} 2(S_{iz}^-) \\ 0 \\ -S_{ix}^- \end{pmatrix}; \ \mu, \nu = A, B. \tag{28}
\]

By solving Eq. (23), we obtain the Green’s functions with the poles

\[
\omega = 0, \ \pm \omega_1, \ \pm \omega_2, \\
\omega_1 = \sqrt{(a + c)^2 + b^2 - d^2 - e^2}, \\
\omega_2 = \sqrt{(a - c)^2 + b^2 - d^2 - e^2}. \tag{29}
\]

Dealing with the pole \( \omega = 0 \) is known to be difficult, in that the anticommutator Green’s function is required.\(^{28}\) However, we can avoid this difficulty by introducing the new expression

\[
G_{A\mu} - G_{A\mu}^- = \frac{1}{2}\omega_1 \left[ \frac{m^x(b + e) - m^x(a + c + d)}{\omega - \omega_1} + \frac{m^x(a + c + d) - m^x(b + e)}{\omega + \omega_1} \right] + \frac{1}{2}\omega_2 \left[ \frac{m^x(b - e) - m^x(a - c - d)}{\omega - \omega_2} + \frac{m^x(a - c - d) - m^x(b - e)}{\omega + \omega_2} \right], \tag{30}
\]

Since the pole \( \omega = 0 \) is absent in this expression, we can use the standard spectral theorem.\(^{29}\) Applying this theorem to Eq. (30), we derive

\[
\frac{1}{2} = \frac{1}{N} \sum_q \left[ m^x(b + e) - m^x(a + c + d) \right] \coth \frac{\beta \omega_1}{2} + \frac{m^x(b - e) - m^x(a - c - d)}{2\omega_2} \coth \frac{\beta \omega_2}{2}. \tag{31}
\]

In Eq. (31), the sum runs over the first Brillouin zone. Moreover, using the fact that the commutator Green’s function has to be regular at the origin,\(^{15}\) i.e.,

\[
\lim_{\omega \to 0} \omega G_{z\mu}^z = 0, \tag{32}
\]

we obtain

\[
m^x = \frac{1}{N} \sum_q \left[ \frac{(b + e)(b + e) - m^x(a + c + d)}{2\omega_1} + \frac{(b + e)(b - e) - m^x(a - c - d)}{2\omega_2} \right]. \tag{33}
\]

From Eqs. (31) and (33), all components of the magnetization, \( m^x \) and \( m^z, \) are determined. As seen in the results in Fig. 2, the magnetization \( m^x \) perpendicular to the magnetic field decreases with increasing the field strength, and disappears around field strength \( B^x/J \approx 4 \) at \( T = 0 \) for \( D^x/J = 0. \)
B. Doping dependence of staggered magnetization

In this subsection, we consider the staggered magnetization of the mean-field Hamiltonian (15) and (16). From the transformation (9), the staggered magnetization in the original representation \(|\langle \hat{S}_\tau^z \rangle|\) is transformed into the pseudospin representation as

\[
|\langle \hat{S}_\tau^z \rangle| \to |\langle (1 - h_\tau^z h_\tau^z) \hat{S}_\tau^z \rangle| = |\langle \hat{S}_\tau^z \rangle| - |\langle h_\tau^z h_\tau^z \hat{S}_\tau^z \rangle| = |\langle \hat{S}_\tau^z \rangle| \equiv M. \tag{34}
\]

Equation (34) shows that the staggered magnetization can be regarded as the component of magnetization perpendicular to the effective magnetic field (to the orientation of pseudospin) in the pseudospin representation. When deriving the relation (34), we use the fact \(\langle h_\tau^z h_\tau^z \rangle = 0\), choosing the orientation of pseudospin along \(z\) axis. Thus the other components of magnetization cannot fulfill the similar relation to Eq. (34). For example, one can easily show that \(|\langle \hat{S}_\tau^x \rangle| \neq |\langle \hat{S}_\tau^y \rangle|\).

Instead of starting from the Heisenberg model (17), we now examine the spin part of the mean-field Hamiltonian (16). After some algebra similar to the one given in Sec. IIIA we obtain

\[
\frac{1}{2} = \frac{1}{N} \sum_\mathbf{q} \left[ \frac{M(b + \tilde{c}) - \tilde{M}(\bar{a} + \tilde{c} + \tilde{d})}{2\tilde{\omega}_1} \coth \frac{\beta \tilde{\omega}_1}{2} 
+ \frac{M(b - \tilde{c}) - \tilde{M}(\bar{a} - \tilde{c} - \tilde{d})}{2\tilde{\omega}_2} \coth \frac{\beta \tilde{\omega}_2}{2} \right], \tag{35}
\]

\[
M = \frac{1}{N} \sum_\mathbf{q} \left[ \frac{(b - \tilde{c})\{M(b + \tilde{c}) - \tilde{M}(\bar{a} + \tilde{c} + \tilde{d})\}}{2\tilde{\omega}_1^2} 
+ \frac{(b + \tilde{c})\{M(b - \tilde{c}) - \tilde{M}(\bar{a} - \tilde{c} - \tilde{d})\}}{2\tilde{\omega}_2^2} \right], \tag{36}
\]

\[
\tilde{\omega}_1 = \sqrt{(\bar{a} + \tilde{c})^2 + \bar{b}^2 - \bar{d}^2 - \tilde{c}^2}, \tag{37}
\]

\[
\tilde{\omega}_2 = \sqrt{(\bar{a} - \tilde{c})^2 + \bar{b}^2 - \bar{d}^2 - \tilde{c}^2}, \tag{38}
\]

with \(\tilde{M} = |\langle \hat{S}_\tau^z \rangle|\), \(\bar{a} = zJ_{\text{eff}} \tilde{M} + B_{\text{eff}}\), \(\bar{b} = zJ_{\text{eff}} \tilde{M}\), \(\tilde{c}_q = zJ_{\text{eff}} \gamma_q \tilde{M}\), \(\tilde{d}_q = 0\), and \(\tilde{e}_q = zJ_{\text{eff}} \gamma_q \tilde{M}\). In addition to Eqs. (35) and (36), the equations for the holon Green’s functions are needed to obtain a closed system of equations. The holon Green’s function are defined as

\[
g_{ij}(t - t') = -i\theta(t - t') \langle [h_i(t), h_j^\dagger(t')] \rangle = \langle \langle h_i; h_j^\dagger \rangle \rangle. \tag{39}
\]

From the holon part of the mean-field Hamiltonian (15), we obtain the following expression of the holon Green’s function;

\[
g_q(\omega) = \frac{1}{\omega - (\tilde{\epsilon}_q - \mu)}, \tag{40}
\]

with \(\tilde{\epsilon}_q = zJ_{\text{eff}} \gamma_q\). Using the spectral theorem\(^{38}\), we also find

\[
\delta = \frac{1}{2N} \sum_\mathbf{q} \left[ 1 - \tanh \frac{\beta(\tilde{\epsilon}_q - \mu)}{2} \right], \tag{41}
\]

\[
\phi = \frac{1}{2N} \sum_\mathbf{q} \gamma_q \left[ 1 - \tanh \frac{\beta(\tilde{\epsilon}_q - \mu)}{2} \right]. \tag{42}
\]

The set of self-consistency equations (45), (46), (47), and (42) are numerically solved. In Figure 3 we show the staggered magnetization and the particle-hole order parameter at \(T = 0\) as functions of doping \(\delta\). The staggered magnetization decreases with increasing \(\delta\), and disappears at the critical doping \(\delta_c\), which is calculated to be \(\delta_c \approx 0.105\) for \(t/J = 3\). In usual mean-field theories, since the single occupancy constraint (2) is treated only on the average, the antiferromagnetic order is generally overestimated. However, our results derived without the constraint are in good accord with the numerical results in Ref. 10, 17, 18, 19, 20.

In this paper, we choose the pseudospin state as \(|\uparrow\rangle\rangle\). If the pseudospin state is chosen as \(|\langle \uparrow\rangle\rangle\rangle\), the direction of the effective magnetic field is aligned along the \(x\) axis, and the staggered magnetization is mapped to the component of magnetization \(|\langle \hat{S}_\tau^x \rangle|\) (perpendicular to the effective field).
IV. SUMMARY

In this paper, we have developed the pseudospin representation for the $t$-$J$ model. By introducing pseudospins associated with empty sites, we rewrote the $t$-$J$ model in terms of local spin and spinless fermionic operators. Using this representation, the $t$-$J$ Hamiltonian can be described without any constraint. The pseudospin representation of the $t$-$J$ Hamiltonian was determined by the orientation of the pseudospin state (the parameters $\theta$, $\varphi$). Within a mean-field level, the spin part of the obtained model was regarded as the antiferromagnetic Heisenberg Hamiltonian in a uniform magnetic field with the correspondence $B_z/\bar{J} \rightarrow B_{z eff}/J_{eff} \equiv -4t\varphi/(J(1-\delta^2-\phi^2)+2t\phi)$. The strength and the direction of the effective field are determined by the doping $\delta$ and the orientation of pseudospins, respectively. Our method yields reasonable value of the critical doping $\delta_c$, at which the antiferromagnetic long-range order disappears, in good agreement with the numerical calculations.\cite{16,17,18,19,20}
