(Dated: July 2, 2013)

In this work we compare the Gunion-Bertsch approximation of the leading order perturbative QCD radiation matrix element to the exact result. To this end, we revisit the derivation of the Gunion-Bertsch approximation as well as perform extensive numerical comparisons of the Gunion-Bertsch and the exact result. We find that when employing the matrix elements to obtain rates or cross sections from phase space integration, the amplitude by Gunion and Bertsch deviates from the correct result in characteristic regions of the phase space. We propose an improved version of the Gunion-Bertsch matrix element which agrees very well with the exact result in all phase space regions.

I. INTRODUCTION

When studying the dynamics of the partonic stage of relativistic heavy ion collisions based on microscopic perturbative QCD (pQCD) processes or on rate equations for such processes, it has been found that elastic interactions alone are not sufficient to describe the evolution of the system [1-4]. Due to the numerical complexity of such dynamic approaches the incorporation of inelastic particle production and annihilation processes has mostly been based on leading order matrix elements. A commonly used approximation to the leading order pQCD matrix element for partonic $2 \leftrightarrow 3$ processes is a result derived by Gunion and Bertsch (GB) in 1981 [5]. This approximation gives a comparatively simple expression for the gluon radiation amplitude in terms of the transverse momentum of the radiated gluon $k_\perp$ and the transverse exchanged momentum $q_\perp$. It has been widely used when solving transport problems [6-13], for example via rate equations or via microscopic transport approaches, most notably the microscopic transport model Boltzmann Approach to MultiParton Scatterings (BAMPS) [14-17]. In Ref. [18-20] some efforts are made to go beyond the soft GB approximation while still obtaining a relatively compact form.

Recently, the results obtained within the BAMPS framework, especially with respect to the computed shear viscosity [21], have been challenged in a paper by Chen et al. [22], who claim that a mis- or double-counting of symmetry factors when applying the GB matrix element to inelastic processes might lead to an overestimation of interaction rates in BAMPS by a factor of 6. Also a recent work by Zhang [23] has addressed this issue and finds numerical discrepancies between cross sections based on the GB approximation compared to full leading order results for the $2 \rightarrow 3$ amplitudes, which have also been known since the early 1980s [24, 25]. The numerical discrepancy found in Ref. [22] is much less pronounced than the one claimed in Ref. [23]. However, it is not fully clear how the results of these two works compare since both use different screening schemes.

In this work we will address these issues in great detail by providing extensive numerical comparisons between the GB approximation and the exact leading order pQCD result as well as by analytically revisiting the derivation of the GB approximation. We will show that the approximation by Gunion and Bertsch needs to be carefully corrected in certain phase space regions when being employed to the computation of cross sections or rates from the matrix element. To this end we propose an improved version of the GB matrix element which is valid in all regions of phase space. However, we want to emphasize that the deviations of rates computed in the original GB approximation compared to rates computed from the improved GB and the exact matrix element are caused deep within the approximations made by Gunion and Bertsch and are not given by simple symmetry factors as argued in Ref. [22].

The paper is organized as follows. After a short revisit of the GB calculation we propose an improved version of the matrix element in Sec. II. In Sec. III the exact matrix elements for $2 \rightarrow 3$ processes are introduced, whereas the phase space integration needed to obtain a total cross section is outlined in Sec. IV. Finally, we will compare the original and improved GB cross section with the exact result and discuss deviations.

II. GUNION-BERTSCH MATRIX ELEMENT

In this section we will argue that the approximation to the leading order pQCD matrix element for $qq' \rightarrow qq'g$ processes (and more generally for other gluon radiation processes as well) as computed by Gunion and Bertsch needs to be carefully corrected when being applied to the computation of cross sections or rates. This correc-
We list the results for the frame of the incoming particles are given in light cone coordinates where in the center of momentum the internal momentum transfer (the momentum of the emitted gluon via rapidity of the emitted gluon via (1) the fraction of light cone momentum carried by the radiated gluon; and (b) respecting the symmetry of the process by explicitly combining results from $A^+ = 0$ and $A^- = 0$ calculations, restricting the emission of gluons to the respective forward direction.

We start by reviewing the derivation of the Gunion-Bertsch approximation, taking the example of $qq' \rightarrow qq'g$ processes as in the original publication. In leading order this process is given by the five Feynman diagrams shown in Figure 1.

In the following we label the 4-momentum of the incoming (outgoing) quarks with $p_1$ and $p_2$ ($p_3$ and $p_4$). The radiated gluon is denoted with $k$, while $q$ is the internal momentum transfer (the momentum of the internal gluon propagator). Furthermore we are working in light cone coordinates where in the center of momentum frame the momenta of the incoming particles are given by

\begin{align}
\vec{p}_1^\prime &= (\sqrt{s}, 0, 0, 0) \\
\vec{p}_2^\prime &= (0, \sqrt{s}, 0, 0)
\end{align}

The Lorentz-invariant quantity

\[ x = k^+ / p_1^+ \]

characterizes the fraction of light cone momentum carried away by the radiated gluon. It can be related to the rapidity of the emitted gluon via

\[ x = \frac{k_\perp}{\sqrt{s}} \]

The Gunion and Bertsch matrix element is derived in the high energy limit, i.e. the radiated gluon and the momentum transfer of the process are soft,

\begin{align}
k_\perp &\ll \sqrt{s} \\
q_\perp &\ll \sqrt{s}
\end{align}

The third approximation explicitly stated by GB relates $k_\perp$, $q_\perp$, and $x$, i.e.

\[ xq_\perp \ll k_\perp \]

With these approximations and from the constraint that all external particles are on-shell one can explicitly specify $k$ and $q$ in light cone coordinates

\begin{align}
k^\mu &= \left( x\sqrt{s}, \frac{k_\perp^2}{\sqrt{s}}, k_\perp \right) \\
q^\mu &= \left( -\frac{q_\perp^2}{\sqrt{s}}, k_\perp^2 / x + q_\perp^2, -2 q_\perp k_\perp / (1 - x) \sqrt{s}, q_\perp \right)
\end{align}

The original computation of the GB approximation has been carried out in light cone gauge, $A^+ = 0$. This implies that the + component of the polarization vector $\epsilon(k)$ is also zero. The physical polarizations of the emitted gluon must be transverse to its momentum, $\epsilon(k) \cdot k = 0$. With these two constraints the two physical polarization vectors, $i = 1, 2$, are given by

\[ \epsilon^{(i)}(k) = \left( 0, 2\epsilon^{(i)}_\perp, \frac{k_\perp}{x\sqrt{s}}, \epsilon^{(i)}_\perp \right) \]

where $\epsilon^{(1)} = (1, 0)$ and $\epsilon^{(2)} = (0, 1)$ are possible choices. For brevity we will suppress the polarization index $(i)$ in the following, keeping in mind that the final polarization sum will simply amount to the replacement $\sum_{\epsilon} |\mathbf{p} \cdot \mathbf{\epsilon}_\perp|^2 = \mathbf{p}^2$.

The evaluation of the Feynman diagrams in the GB approximation is detailed in [appendix A]. We list the results here:

\begin{align}
i M_{11}^{qq'\rightarrow qq'g} \approx \left. ig^3 \lambda_j^a \lambda_m^a \lambda_{ij} \lambda_{mn} \delta_{\mu
u} \delta_{\omega\nu} \frac{2s}{q_\perp} (1 - x) \frac{2k_\perp \cdot \epsilon}{k_\perp^2} \right|_{\mu, \nu, \omega, \nu} \\
i M_{22}^{qq'\rightarrow qq'g} \approx -\left. ig^3 \lambda_j^a \lambda_m^a \lambda_{ij} \lambda_{mn} \delta_{\mu
u} \delta_{\omega\nu} \frac{2s}{q_\perp} (1 - x) \frac{2k_\perp \cdot \epsilon}{k_\perp^2} \right|_{\mu, \nu, \omega, \nu} \\
i M_{33}^{qq'\rightarrow qq'g} \approx 0 \\
i M_{44}^{qq'\rightarrow qq'g} \approx 0 \\
i M_{55}^{qq'\rightarrow qq'g} \approx \left. g^3 f^{abc} \lambda_j^a \lambda_m^a \lambda_{ij} \lambda_{mn} \delta_{\mu
u} \delta_{\omega\nu} \frac{2s}{q_\perp} (1 - x) \frac{2(q_\perp - k_\perp) \cdot \epsilon}{(q_\perp - k_\perp)^2} \right|_{\mu, \nu, \omega, \nu}
\end{align}

Note that the diagrams corresponding to radiation from the lower quark line are either exactly (diagram 4) or approximately (diagram 3) zero in the $A^+ = 0$ gauge.
The common $\frac{2s}{q^2}$ factors are already indicative of what after squaring the amplitude will be the factorized contribution of the elastic \(qq'\rightarrow qq'\) process in small angle approximation.

Using \([\lambda^u,\lambda^v]_{\mu\nu} = i\bar{f}^{abc}\lambda^a_{\mu\nu}\lambda^b_{\nu\alpha}\delta_{\xi_\mu}\delta_{w_\alpha}\) the sum of the five diagrams, Eq. (10) \(i\mathcal{M}_{qq'\rightarrow qq'} = \sum_{j=1}^{5} i\mathcal{M}_{qq'\rightarrow qq'}^j\), can be computed

\[
i\mathcal{M}_{qq'\rightarrow qq'}^j \simeq -g^3 f^{abc}\lambda^a_{\mu\nu}\lambda^b_{\nu\alpha}\delta_{\xi_\mu}\delta_{w_\alpha} \frac{2s}{q^2} (1 - x)
\times 2e_+ \left[ \frac{k_+}{k_{\perp}^2} + \frac{q_+ - k_+}{(q_{\perp} - k_+)^2} \right].
\] (11)

Squaring the amplitude and taking the average over the initial and sums over the final spin and color states yields

\[
\left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2 \simeq \frac{24}{9} g^6 \frac{4s^2}{q_+^2} (1 - x)^2 \left[ \frac{k_+}{k_{\perp}^2} + \frac{q_+ - k_+}{(q_{\perp} - k_+)^2} \right]^2
\times \frac{24}{9} g^6 \frac{4s^2}{q_+^2} (1 - x)^2 \frac{q_+^2}{k_{\perp}^2(q_{\perp} - k_+)^2}^2.
\] (12)

Note that the algebraic simplification employed when going from the first to the second line of (12) is strictly only valid when not screening the propagator terms \(1/k_{\perp}^2\) and \(1/(q_{\perp} - k_+)^2\) with a Debye mass, cf. section V.

When introducing the squared amplitude for the elastic \(qq'\rightarrow qq'\) process in the usual small angle (sa) approximation, \(\left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2 = \frac{2}{9} g^4 4s^2/q_+^4\), Eq. (12) can be rewritten as

\[
\left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2 \simeq 12g^2 \left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2_{sa} (1 - x)^2 \times \frac{q_+^2}{k_{\perp}^2(q_{\perp} - k_+)^2},
\] (13)

explicitly demonstrating that in the high energy limit the matrix element of the 2 \(\rightarrow\) 3 process factorizes into an elastic 2 \(\rightarrow\) 2 part and a gluon emission amplitude.

The factor \((1 - x)^2\) in Eqs. (12) or (13) leads to a sizable suppression of the amplitude at forward rapidity, where \(x > k_+ / \sqrt{s}\), which is immediately evident from Eq. (4).

At the maximal rapidity that is kinematically allowed for a given transverse momentum, \(y_{\text{max}} = \ln(k_+ / \sqrt{s})\), \(x\) is 1 and the factor \((1 - x)^2\) completely suppresses the matrix element. While Gunion and Bertsch have the \((1 - x)\) terms in their intermediate results for the single diagrams, cf. (10) they were mostly interested in emission spectra in the mid-rapidity region, \(x \approx k_+ / \sqrt{s} \ll 1\), and thus omitted the \((1 - x)\) terms from their final results.

The amplitude then simplifies to

\[
\left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2 \simeq 12g^2 \left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2_{sa} \frac{q_+^2}{k_{\perp}^2(q_{\perp} - k_+)^2},
\] (14)

which is the formula that has been mostly used in the literature as the GB matrix element since then [3 12] and that has also been implemented in the transport model BAMPS [13]. When computing cross sections or rates from Eqs. (12) or (13) however, the phase space integration covers the entire accessible rapidity region and factors \((1 - x)\) must not be omitted. Thus Eqs. (12) or (13) rather than Eq. (14) need to be employed when computing rates for \(2 \rightarrow 3\) processes in the GB approximation.

The second modification that has been mentioned at the beginning of this section is somewhat more subtle. In order to arrive at the simple results for the single diagrams as noted in (10) when not setting \(x \approx k_+ / \sqrt{s} \approx 0\), approximations are necessary that require (see appendix A for more details)

\[
x^2 s \gg k_+^2
\] (15)
or equivalently

\[
k^+ \gg k^- \iff y \gg 0.
\] (16)

The results Eqs. (12) and (13) are thus only valid at mid-rapidity, where terms \(\sim x\) can be neglected, and for forward emitted gluons, where \(x^2 s \gg k_+^2\) holds, but not in the backward rapidity region. The requirement (15) goes beyond the approximations (5) and (6) and has not been mentioned in the original GB publication.

Qualitatively, the need for a restriction such as Eqs. (15) or (16) can be understood when noting that the process \(qq' \rightarrow qq'\) is symmetric in interchanging \(q\) and \(q'\) and therefore the resulting amplitude should be symmetric in the rapidity of the emitted gluon. Terms including \(x\), however, are evidently not symmetric in \(y\), cf. Eq. (4) and thus the results (12) and (13) do not obey the symmetry that should be present. This consideration nicely matches the analytic finding that (12) and (13) are valid only in the forward and mid-rapidity region.

One can, however, carry out the same calculation in the \(A^- = 0\) gauge. In this gauge diagrams 3, 4 and 5 have sizable contributions, while diagrams 1 and 2 do not contribute to the final amplitude. Setting

\[
x' = \frac{k_+}{\sqrt{s} \alpha e^{-y}}
\] (17)

the result for the averaged squared matrix element in \(A^- = 0\) gauge reads

\[
\left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2 \simeq 12g^2 \left|\mathcal{M}_{qq'\rightarrow qq'}\right|^2_{sa} (1 - x')^2 \times \frac{q_+^2}{k_{\perp}^2(q_{\perp} - k_+)^2}.
\] (18)

This is simply the result obtained from the \(A^+ = 0\) gauge, cf. (13) with \(x\) being replaced by \(x'\). Since both results are also valid at mid-rapidity it is self-evident to combine
Eqs. (12) and (18) to

\[ |\mathcal{M}_{qg'\to qg'}|^2 \simeq 12g^2 |\mathcal{M}_{qg'\to qg'}|_{sa}^2 \frac{q_1^2}{k_1^2(q_\perp - k_\perp)^2} \times \left[ (1 - x)^2 \Theta(y) + (1 - x')^2 \Theta(-y) \right] = 12g^2 |\mathcal{M}_{qg'\to qg'}|_{sa}^2 (1 - \bar{x})^2 \times \frac{q_1^2}{k_1^2(q_\perp - k_\perp)^2} \]  

(19)

where we have defined

\[ \bar{x} = \frac{k_\perp}{\sqrt{s}} |y| . \]  

(20)

In the following we will refer to this result as the improved GB matrix element since it is not only valid at mid-rapidity, but also at forward and backward rapidity. In Sec. III we will compare this result to the exact matrix element without any approximation, which is briefly discussed in Sec. III.

As a note, the idea of decomposing the phase space in forward and backward rapidities was also used in Ref. [20] for the inelastic scattering of a light and heavy quark in the GB approximation, although the \((1 - \bar{x})^2\) factor was neglected.

The observed factorization of the GB matrix element into an elastic part and a gluon emission amplitude in the high energy limit, cf. Eq. (13) immediately implies that the GB calculation is also valid for other 2 \(\to\) 3 processes, such as \(qg \to qgg\) or \(gg \to ggg\). In the high energy limit of the GB approximations the specific nature of the scattering particles becomes irrelevant for the structure of the resulting matrix elements. Therefore, Eq. (19) also holds for processes other than the one explicitly considered here, if one takes into account the different color prefactors of the corresponding 2 \(\to\) 2 small angle amplitudes,

\[ |\mathcal{M}_{gg\to gg}|_{sa}^2 = \left(\frac{9}{4}\right)^2 |\mathcal{M}_{qg'\to qg'}|_{sa}^2 . \]  

(21)

III. EXACT MATRIX ELEMENT

The exact matrix elements for the 2 \(\to\) 3 processes involving light partons have been calculated in Refs. [24, 25]. For \(qg' \to qg'g\) the result is relatively simple, [24].

\[
\begin{align*}
|\mathcal{M}_{qg'\to qg'}|^2 &= \frac{g^6}{8} \left[ (s^2 + s'^2 + u^2 + u'^2)/(tt') \right] [(p_1 k)(p_2 k)(p_3 k)(p_4 k)]^{-1} \\
&\times \left\{ C_1 [(u + u') (ss' + tt' - uu') + u(st + s't') + u'(st' + s't')]ight. \\
&\quad - C_2 [(s + s') (ss' - tt' - uu') + 2tt'(u + u') + 2uu'(t + t')]) \right\} ,
\end{align*}
\]

(22)

with the constants \(C_1 = (N^2 - 1)^2/4N^3\) and \(C_2 = (N^2 - 1)/4N^3\) where \(N = 3\) is the number of colors. The Mandelstam variables for the 2 \(\to\) 3 process are defined as

\[
\begin{align*}
\quad s &= (p_1 + p_2)^2 & t &= (p_1 - p_3)^2 & u &= (p_1 - p_4)^2 \\
\quad s' &= (p_3 + p_4)^2 & t' &= (p_2 - p_4)^2 & u' &= (p_2 - p_3)^2
\end{align*}
\]

(23)

However, the expression for the matrix element has been simplified to such an extent that it is not obvious anymore how to identify the internal propagators which are usually screened with a mass of the order of the Debye mass in thermal QCD. We do not explicitly quote the result for \(qq \to qgg\) here, it is also given in [24].

The expression for \(gg \to qgg\) is considerably more complicated, but can still be expressed in a relatively compact form due to its symmetry [24].

\[
\begin{align*}
|\mathcal{M}_{gg\to gg}|^2 &= \frac{g^6}{2} \left[ N^3/(N^2 - 1) \right] [(12345) + (12354) + (12435) + (12453) + (12534) \\
&\quad + (13453) + (13454) + (13524) + (13542) + (14235) + (14325)] \\
&\times \frac{(p_1 p_2)^4 + (p_1 p_3)^4 + (p_1 p_4)^4 + (p_2 p_3)^4 + (p_2 p_4)^4 + (p_2 p_5)^4 + (p_3 p_4)^4 + (p_4 p_5)^4}{(p_1 p_2)(p_1 p_3)(p_1 p_4)(p_1 p_5)(p_2 p_3)(p_2 p_4)(p_2 p_5)(p_3 p_4)(p_3 p_5)(p_4 p_5)}
\end{align*}
\]

(24)

with \((ijklm) = (p_ip_j)p_k p_l p_m p_n\) and \(p_5\) being the momentum of the third outgoing gluon. In our notation \(p_5 = k\). As for the other matrix elements, it
is not a priori obvious how one would screen this matrix element. For the purpose of this work we introduce a cut-off prescription in Sec. V that regulates the divergencies when calculating the total cross section and allows for consistent comparisons to the GB result.

IV. PHASE SPACE INTEGRATION FOR CROSS SECTIONS

In the previous sections the leading order pQCD matrix elements for radiative processes have been introduced both in their exact form and in the (improved) approximation by Gunion and Bertsch. These matrix elements depend on four independent phase space variables. A possible choice for these variables that is most appropriate for the GB approximation of the matrix element is shown later in this section, cf. Eq. (26). In the following we outline the procedure for the phase space integration that is needed to obtain the total cross section from the matrix elements presented in Sections II and III. Full energy and momentum conservation are taken into account. In general, differential cross sections (e.g. \( d\sigma/d\Omega \)) can be obtained from this procedure by projecting out variables with delta functions (e.g. \( \delta(y) \)). It is these differential and total cross sections that are then used in Section V to numerically check the improved GB approximation against the known exact result as they are easier to visualize than the bare matrix elements.

The total cross section of a 2 \( \rightarrow \) 3 process is defined by

\[
\sigma_{2\rightarrow3} = \frac{1}{2E_1 2E_2 \nu_{rel}} \int \frac{d^3p_1}{(2\pi)^3} \frac{d^3p_2}{(2\pi)^3} \frac{d^3k}{(2\pi)^3} \times (2\pi)^4 \delta^4(p_1 + p_2 - (p_3 + p_4 + k)) |\mathcal{M}_{2\rightarrow3}|^2 , \quad (25)
\]

where we used the same notation as before. The relative velocity is defined by \( \nu_{rel} = \sqrt{(P_1^2 + P_2^2) - m_1^2 - m_2^2 - E_1 E_2} \) and the symmetry factor \( \nu = n! \) accounts for \( n \) identical particles in the final state. Note that this symmetry factor is not needed when computing cross sections from the (improved) GB matrix element. In this case the specific choice and identification of the outgoing momenta, where \( p_5 = k \) is the momentum of the radiated gluon, selects a specific configuration and thus obviates the need for a symmetry factor /\( \nu \). This is taken into account for all calculations involving the original or improved GB matrix elements in this paper and has also been correctly implemented in BAMP's from the beginning [14].

Equation (25) can be used to calculate the total cross section of the GB and exact matrix elements by performing the nine-dimensional integration. However, it is numerically more efficient to analytically integrate out the delta function to end up with only a five dimensional integration, which can be reduced to a four dimensional integration by performing one angle integration directly. After this and switching to the GB coordinates from Sec. I the total cross section reads [3]

\[
\sigma_{2\rightarrow3} = \frac{1}{256 \pi^4 \nu s} \int \frac{dy_3}{y_{min}} \int \frac{dk_\perp^2}{k_{min}^2} \int \frac{dy}{y_{max}} \int \frac{d\phi}{\pi} \times |\mathcal{M}_{2\rightarrow3}|^2 \left( \frac{\partial F}{\partial y_3} \right)^{-1} , \quad (26)
\]

where \( y_3 \) denotes the rapidity of particle 3 and \( \phi \) the angle between \( q_\perp \) and \( k_\perp \). The available phase space limits the rapidity to \( y_{max/\min} = \pm \text{arccosh} [\sqrt{\sqrt{s}/2k_\perp}] \). Due to the transformation of the delta function, \( (\partial F/\partial y_3)^{-1} \) must be summed over the roots of

\[
F = (p_1 + p_2 - p_3 - k)^2 = s - 2\sqrt{s} (y_\perp \cosh y_3 + k_\perp \cosh \phi) + 2q_\perp k_\perp (\cosh y_3 \cosh y - \sinh y_3 \sinh y) . \quad (27)
\]

We have numerically checked that both Eqs. (25) and (26) give the same results for the GB and exact matrix elements, respectively.

V. NUMERICAL COMPARISON

We have carried out extensive numerical comparisons between the exact matrix element and the matrix element calculated in the GB approximation. In order to obtain a picture as complete as possible we have investigated differential cross sections such as \( d\sigma/d\Omega \), \( d\sigma/dx \), \( d\sigma/dk_\perp dq_\perp \) in addition to the total cross section. All calculations take into account the full kinematics according to Eqs. (25) or (26) ensuring energy and momentum conservation.

Both the exact and GB matrix elements are divergent for infrared and collinear configurations. In thermal quantum field theory these divergencies can be cured by loop resumations of the propagator, which leads to an extra term with the self energy in the propagator. Phenomenologically, this self energy can be mimicked with a Debye mass \( m_D \) that modifies the propagator terms and makes them infrared-safe,

\[
\frac{1}{q_\perp^2} \rightarrow \frac{1}{q_\perp^2 + m_D^2} . \quad (28)
\]

However, due to their compact notation it is not straightforward to identify the propagator terms in the exact matrix elements. Therefore, for all numerical calculations of total or differential cross sections from both the exact and the GB matrix elements we choose a simple cut-off procedure to cure the divergencies. The integrand is set to zero when the scalar product of any incoming or outgoing 4-momenta is smaller than a cut-off \( \Lambda^2 \), \( p_i \cdot p_j < \Lambda^2 \) with \( i, j = 1...5 \). Formally this is expressed by multiplying the integrand in Eq. (25) with

screening only propagator terms. The resulting numeri-
strictions to the phase space potentially go beyond Debye

This cut-off prescription allows for consistent and well-
cal values for the total or differential cross sections need
ranging over the entire

(29)

It is immediately obvious from Eq. [24] that this prevents
divergencies of the integrand. For propagator terms this
scheme acts similar to the Debye screening, but the re-
strictions to the phase space potentially go beyond Debye
screening only propagator terms. The resulting numerical-
values for the total or differential cross sections need
thus not be the physically correct values and are conse-
quently given in arbitrary units where necessary. Still
this cut-off prescription allows for consistent and well-
declared comparisons between the GB approximation and
the exact leading order matrix elements which is the fo-
cus of this study. If not mentioned otherwise, we set
ε = 0.001 to reduce the screening effect as much as possi-
ble. In the last part of the section we will discuss the im-
 pact of different ε and compare this cut-off procedure to
the standard Debye screening procedure for more physi-
cal scenarios.

The calculations in the remainder of the section are
done for a temperature of \(T = 400 \text{ MeV}\). The coupling
is set constant, \(\alpha_s = 0.3\). If not stated otherwise, we use the
average thermal value for massless particles for the
squared center of mass energy, \(s = 18T^2 \simeq 2.88 \text{ GeV}^2\),
and determine \(\Lambda\) from the usual gluon Debye mass for
Boltzmann statistics, \(m_D^2 = \frac{\kappa^2}{2}(N_c + n_f)T^2\). For \(n_f = 3\)
at the given temperature and coupling, the Debye mass is
\(m_D^2 \simeq 0.73 \text{ GeV}^2\).

Figure 2 compares the rapidity spectrum of the emitted
gluon as given by different approximations of the matrix
element by depicting the differential cross section \(d\sigma/dy\)
for the process \(qq' \rightarrow qq'g\). This process is the clearest to
study since only one (the emitted) gluon is involved. Fur-
thermore, it is the process that has been studied in the
original GB publication, cf. section II. The plot nicely
demonstrates the shortcomings of the standard GB ma-
trix element, Eq. [14] in the forward and backward re-

The exact matrix element, Eq. [22] only peaks at mid-
rapidity and does not have any sizable contribution at forward or backward rapidity. The gluon emission into
the forward and backward region is suppressed since the
phase space is occupied by the two quarks which just
scatter off with a small angle. Furthermore, the cross
section is symmetric in the rapidity of the emitted gluon
as it must be for this process. The standard GB matrix
element without the \((1 - x)^2\) term (Eq. [14]) is very
similar at mid-rapidity, but has two additional large con-
tributions at forward and backward rapidity. Thus this
matrix element would allow that, for instance, the gluon
is emitted into the backward region and that one of the
quarks is located at mid-rapidity. Although the matrix
element itself is symmetric in \(y\), the curve is not since in
our implementation the \(p_z\) of particle 3 is restricted to
positive values to ensure that the particle only scatters
off with a small angle.

The matrix element with the GB approximation and
the term \((1 - x)^2\), Eq. [12] has the same value at mid-
rapidity as the other matrix elements since \(x\) is small in
this region. However, at forward rapidity the \((1 - x)^2\) fac-
tor leads to a significant reduction compared to the pure
GB result. Here the curve lies right on top of the curve
from the exact matrix element. Nevertheless, as dis-

cussed in Sec. II the curve with \((1 - x)^2\) is not symmetric
anymore due to the asymmetric \(y\)-dependence contained in \(x\).

The last curve in Fig. 2 shows the cross section of
our proposed improvement of the GB matrix element,
Eq. [19] At forward and mid-rapidity it agrees with the
previously mentioned curve. At backward rapidity the
modified \((1 - x)^2\) term removes the excess and reconciles
the shape of the GB approximation with the symmetry
of the process.

The overall agreement between the differential cross
sections from the improved matrix element and from the
exact result is remarkably good. The difference between
the approximation and the exact result is on the level of
a few percent over the entire \(y\)-range. This striking agree-
ment is also visible in other differential cross sections such
as \(d\sigma/dq_T^2\,dk_T^2\) and \(d\sigma/dx\). In Fig. 3 the transverse mom-
entum distributions \(d\sigma/dk_T^2\) and \(d\sigma/dq_T^2\) are depicted.
At small \(k_T^2\) and \(q_T^2\), where the contribution to the cross
section is largest, the deviation between the improved
GB and the exact result is less than 5 %. The asymmetry
between the \(k_T^2\) and \(q_T^2\) distributions is due to an interplay
between the cut-offs and the \((1 - x)\) factor for the GB

\footnote{This constraint is necessary if one transforms from Mandelstam \(t\) to \(q_T^2\) for such a small angle favoring process, since \(q_T^2\) can be
small for a outgoing particle which moves exactly in the other
direction than it moved before the reaction, but in this case the
scattering angle is not small anymore, thus, \(t\) becomes large and
\(t \simeq q_T^2\) does not hold anymore.}
the ratios of the total cross sections shows the dependence of the total cross section of all outgoing gluons in Figure 4 for \( qg \rightarrow qg'g \) calculated with the exact (Eq. (22)) and improved GB (Eq. (19)) matrix element.

Figure 5. Ratio of total cross section \( \sigma_{2 \rightarrow 3} \) of the improved GB matrix element (Eq. (19)) to the exact one (see Sec. III) as a function of \( s \) for \( qg \rightarrow qg'y, qg \rightarrow qgg, \) and \( gg \rightarrow ggg \). In addition, the ratio of the original GB cross section (14) as it was previously implemented in BAMPS to the exact cross section is plotted for \( gg \rightarrow ggg \).

Figure 4. Differential cross section \( d\sigma/dy \) for all outgoing gluons for the process \( gg \rightarrow qgg \) calculated with the exact and improved GB matrix element.

Figure 3. Differential cross sections \( d\sigma/dk_T^2 \) and \( d\sigma/dq_T^2 \) as a function of \( k_T^2/s \) and \( q_T^2/s \), respectively, for the process \( qg' \rightarrow qg'y \) calculated with the exact (Eq. (22)) and improved GB (Eq. (19)) matrix element.

and exact matrix elements agree nicely, it is not a surprise that this is also true for the total cross sections. In Figure 5 the ratios of the total cross sections \( \sigma_{2 \rightarrow 3} \) for different processes from the improved GB to those obtained from the exact matrix elements are depicted as a function of the squared center of mass energy \( s \). The exact and improved cross sections agree very well for all processes and virtually all \( s \). Only at very small \( s \), below the thermal average \( s = 18T^2 \approx 2.88 \text{GeV}^2 \), there is a slight discrepancy up to about 40\%. The original GB cross section for \( gg \rightarrow ggg \) as it was previously implemented in BAMPS is about a factor of three larger than the exact cross section. The same is true for the other processes (not plotted).

Figure 5 shows the dependence of the total cross section on the cut-off \( \epsilon = \Lambda^2/m_T^2 \). The improved GB matrix element works best for small \( \epsilon \) where the matrix elements are dominated by small \( k_\perp \) and \( q_\perp \). At larger \( \epsilon \) most of the phase space at small \( k_\perp \) and \( q_\perp \) is cut away and other phase space regions play the dominant role, in which the GB approximation is not as good. Hence, the ratio rises. At \( \epsilon \gtrsim 0.6 \) (indicated by the grey band in the figure) the cut-off is so large that the entire available phase space is cut away and the GB as well as exact cross sections are zero. For such severe cut-offs the comparison scheme is not reliable any more and the previously introduced Debye screening would be more realistic. However, the comparison to the exact matrix element with standard Debye screening is not done in this paper since the identification of the propagators in the compact results of the exact matrix elements is not known. Also note that Fig. 5 is made for thermal \( s = 18T^2 \). For larger values of \( s \) the cut-off parameter \( \epsilon \) at which the ratio deviates from unity becomes significantly larger. Thus, in summary, the improved GB approximation works best for larger \( s \) and/or
we explicitly compare the improved GB differen-

1	ions. For bulk dynamics, where the mean s is smaller, it is important how strong the screening effects actually are and if one is already in the regime of large \( \epsilon \) where the improved GB matrix element might deviate from the exact matrix element. To explore this in more detail, in Fig. 6 we explicitly compare the improved GB differential cross section obtained from the cut-off procedure to the one obtained using the standard Debye screening according to Eq. (28) which is for \( qq' \rightarrow qq'g \) (cf. Eqs. (12) and (19))

\[
|M_{qq' \rightarrow qq'g}|^2 = \frac{32}{3} \frac{g^6 s^2}{(q_{\perp}^2 + m_D^2)^2} (1 - \bar{x})^2 \\
\times \left[ \frac{s}{k_{\perp}^2 + m_D^2} + \frac{q_{\perp} - k_{\perp}}{(q_{\perp} - k_{\perp})^2 + m_D^2} \right]^2.
\]

(30)

Now to get a feel for the quality of the improved GB approximation for Debye screened thermal processes one can either try to match the total cross sections or the differential cross sections \( d\sigma/dy \) at mid-rapidity. Doing this, the necessary parameter \( \epsilon \) can be determined to be of the order of \( \epsilon \approx 0.4 \) to 0.5. As can be seen from Fig. 6 the deviations between the improved GB and exact result in this \( \epsilon \) region vary roughly between \( \sigma/\sigma_{\text{exact}} \approx 4 \) and \( \sigma/\sigma_{\text{exact}} \approx 9 \). However, Fig. 7 also clearly demonstrates the distortion of the phase space due to extreme choices of the cut-off. Large rapidities are cut away entirely while the standard Debye screening procedure leaves the whole phase space available. It is questionable whether the strong cuts in the cut-off procedure make physical sense. The comparison is thus a rather qualitative one and should be regarded as a first estimate of the quality of the (improved) GB approximation in the region of thermal processes with a standard Debye screening.

As discussed in Section II the factorization of the GB approximation into an elastic \( 2 \rightarrow 2 \) part and a radiation amplitude features the elastic amplitude in small angle approximation, \( \overline{|M_{2\rightarrow2}|^2} \propto 1/q_{\perp}^4 \). If one, however, instead employs the exact binary matrix element for the \( t \) channel which is

\[
\overline{|M_{2\rightarrow2}|^2} \propto \frac{1}{t^2},
\]

(31)

the agreement between the exact and the improved GB result becomes much better at large \( \epsilon \), which is illustrated in Figure 8. The ratio is of the order of 1 over the entire \( \epsilon \) range and the deviation is at most 50% for all processes. In contrast to the previous result with the approximated \( 2 \rightarrow 2 \) matrix element (cf. Fig. 6), the ratio for small \( \epsilon \) is not 1 anymore, but 0.9. This is probably due to the fact that different approximations are employed for the \( 2 \rightarrow 2 \) and the radiative part of the matrix element. However, since the numerical agreement is so good also in the region of thermal processes at larger \( \epsilon \), the combination of the improved GB approximation (19) for the radiation amplitude with the exact \( 2 \rightarrow 2 \) part (31) might be implemented in our transport model BAMPS.

---

2 The implementation in BAMPS does not screen the \( 1/k_{\perp}^2 \) term in the bracket since small \( k_{\perp} \) are regularised by the LPM effect [29]. However, since the LPM effect is not employed in this study, we regularise also this term with the Debye mass.
Figure 8. As Fig. 9 but in addition the improved GB cross section with the exact $2 \rightarrow 2$ matrix element $(22 t)$ instead of the $2 \rightarrow 2$ matrix element in small angle approximation $(22 q_\perp)$.

VI. SUMMARY

The inelastic gluon Bremsstrahlung matrix element derived by Gunion and Bertenschl for $qq' \rightarrow qq'g$ has been compared to the exact matrix element for this process by performing full phase space integrations and analyzing the total and differential cross sections. Although it agrees very well with the exact result at mid-rapidity (the region in which Gunion and Bertenschl were mainly interested in) large deviations have been found at forward and backward rapidity. Based on a detailed analytic investigation of the underlying approximations, we propose an improved version of the GB matrix element which agrees very well in all phase space regions with the exact result. This remarkable agreement holds for virtually all center of mass energies $\sqrt{s}$ and most cut-off parameters $\epsilon$ as well as for the other radiative processes $qq \rightarrow ggg$ and $gg \rightarrow ggg$

In contrast to the claim in Ref. 22, the deviation between the GB matrix element and the exact result does not originate from a miscounting of symmetry factors, but lies deep in the approximations of GB in forward and backward rapidities. Although the reasoning in Ref. 22 accidentally (and thus only effectively) holds for $gg \rightarrow ggg$ due to the symmetry of the process, it fails for asymmetric processes such as $qq \rightarrow ggg$ or $qq' \rightarrow qq'g$.

The implementation of the new improved GB matrix element in our transport model BAMPS is currently underway. From Fig. 8 we expect at most a factor of 3 difference in the rates, although this should be reduced by the iterative computation of cross sections due to the implementation of the LPM effect 27. The difference in the phase space sampling of the outgoing particles will have a large impact in particular on jet observables. For instance, we expect much less suppression of high energy particles, which will increase the small nuclear modification factor of BAMPS 17, 27 and bring it closer to the data. The effect on bulk observables will also be of great interest. Although we expect a decrease of the elliptic flow 16 and an increase of the shear viscosity 21, one must wait for the numerical results to see how large the effect will actually be. As part of this study we will also implement the running coupling for elastic and radiative processes which is expected to lead to a rising $R_{AA}$ curve with transverse momentum. Furthermore, we plan to generalize the new improved GB matrix element also to the heavy flavor sector and study its impact on the heavy quark energy loss 28, 30.

ACKNOWLEDGEMENTS

We would like to thank J. Aichelin, A. Dumitru, P.B. Gossiaux, and A. Peshier for stimulating and helpful discussions. This work was supported by the Bundesministerium für Bildung und Forschung (BMBF) and by the Helmholtz International Center for FAIR within the framework of the LOEWE program launched by the State of Hesse. Numerical computations have been performed at the Center for Scientific Computing (CSC). J.U. is grateful for the kind hospitality at Tsinghua University, where part of this work has been done. Furthermore, J.U. would like to thank the DAAD and the Helmholtz Research School for Quark Matter studies for financial support. Z.X. is supported by the NSFC under grant No. 11275103.

Appendix A: Detailed GB calculation

The purpose of this appendix is to provide some more details on the computation of the $qq' \rightarrow qq'g$ matrix element in the Gunion and Bertsch approximation, cf. Sec. 11 and the diagrams shown in Figure 1. The focus is on highlighting crucial steps and approximations that are needed to arrive at the results in Eq. (10)

We define

$$ J_{rs}^\mu(p, p') = \pi(p) \gamma^\mu u^s(p') \text{,} \quad (A1) $$

where $s$ and $r$ are the spin indices of the spinors $u$ and $\pi$. Setting $p' = p + q$ and assuming that $q \ll p$, the Gordon identity 31 for (A1) can be simplified to give

$$ J_{rs}^\mu(p, p + q) \simeq (2p + q)\gamma^\mu \delta_{rs} \text{.} \quad (A2) $$

This eikonal approximation essentially amounts to describing the problem in scalar QCD and is responsible for the fact that the amplitudes of different $2 \rightarrow 3$ processes only differ by the color factor of the factorized elastic amplitude, cf. Eq. (21) Furthermore we define

$$ \Gamma_{rs}^{\mu\nu}(p, k, p') = \pi(p) \gamma^\mu (k + m) \gamma^\nu u^s(p') = \sum_t J_{rt}^\mu(p, k) J_{ts}^\nu(k, p') \text{.} \quad (A3) $$
With these definitions and the kinematics as given in Sec. III we can compute the matrix elements of the diagrams.

**Diagram 1**

The Feynman rules for diagram 1, cf. Figure 1, give

\[ i\mathcal{M}_{1}^{q'\rightarrow qq'g} = \frac{F_1}{q^2(p_1 + k)^2} \Gamma_{\mu}^{\nu\rho}(p_3, p_1 + k, p_1) \times \epsilon^\ast_1(k) g_{\mu\nu} J_{\nu\rho}^{\ast}(p_4, p_2) \]

\[ \approx \frac{F_1}{q^2(p_1 + q)^2} (2p_1 + q)^\mu (2p_2 - q)_\mu \times (2p_1 + 2q - k)^\alpha \epsilon^\ast_1(k) \]

(A4)

with \( F_1 = -ig^3 \lambda^a_{\alpha\beta} \lambda^b_{\mu\nu} \delta^{ac} \). Employing the kinematic approximations from Sec. III to the single terms

\[ (p_1 + q)^2 \approx \frac{(k_1 - x q_\perp)^2}{(1 - x)x} \]

(2p_1 + q)^\mu (2p_2 - q)_\mu \approx 2s \]

(2p_1 + 2q - k)^\alpha \epsilon^\ast_1 \approx 2 \times (k_\perp - x q_\perp) \cdot q_\perp \]

(A5)

(A6)

(A7)

together with \( q^2 \approx -q_\perp^2 \) and (6) yields the result listed in Eq. [10]. Eq. (A6) requires the restriction \( x^2 s \gg k^2 \)

and (6).

**Diagram 2**

The Feynman rules for diagram 2 give

\[ i\mathcal{M}_{2}^{q'\rightarrow qq'g} = \frac{F_2}{q^2(p_1 + k)^2} \Gamma_{\mu}^{\nu\rho}(p_3, p_1 - k, p_1) \times \epsilon^\ast_1(k) g_{\mu\nu} J_{\nu\rho}^{\ast}(p_4, p_2) \]

\[ \approx \frac{F_2}{q^2(p_1 + k)^2} (2p_1 + q - 2k)^\mu (2p_2 - q)_\mu \times (2p_1 - k)^\alpha \epsilon^\ast_1(k) \]

(A8)

with \( F_2 = -ig^3 \lambda^a_{\alpha\beta} \lambda^b_{\mu\nu} \delta^{ac} \). The kinematic approximations

\[ (p_1 - k)^2 \approx -k^2 x \]

(2p_1 + q - 2k)^\mu (2p_2 - q)_\mu \approx 2s \times (1 - x) \]

(2p_1 - k)^\alpha \epsilon^\ast_1 \approx 2 \times (k_\perp - q_\perp) \cdot q_\perp \]

(A9)

(A10)

(A11)

together with \( q^2 \approx -q_\perp^2 \) lead to the result listed in Eq. [10]. Again Eq. (A10) requires the restriction to forward emission, \( x^2 s \gg k^2 \), in addition to the standard GB approximations (5) and (6).

**Diagram 3**

In order to explicitly compute diagrams 3 and 4 the components of the momentum transfer \( q \) need to be redefined from the on-shell conditions \( (p_2^2 = (p_1 + q)^2 = 0 \) and \( p_1^2 = (p_2 - q - k)^2 = 0 \) and the choice of keeping \( k \) in the form given in Eq. (7).

\[ q^\mu \approx \left( -x \sqrt{s} \frac{q_\perp^2}{\sqrt{s}} q_\perp \right) \]

(A12)

With this definition diagram 3 can be evaluated as

\[ i\mathcal{M}_{3}^{q'\rightarrow qq'g} = \frac{F_3}{q^2(p_1 + k)^2} J_{\mu}^{\nu\rho}(p_3, p_1) g_{\mu\nu} \times \epsilon^\ast_1(k) \]

\[ \approx \frac{F_3}{q^2(p_2 - q)^2} (2p_1 + q)^\mu (2p_2 - q)_\mu \times (2p_2 - 2q - k)^\alpha \epsilon^\ast_1(k) \]

(A13)

with \( F_3 = -ig^3 \lambda^a_{\alpha\beta} \lambda^b_{\mu\nu} \delta^{ac} \). Employing the usual kinematic approximations simplifies the single terms

\[ (p_2 - q)^2 \approx x s \]

(2p_1 + q)^\mu (2p_2 - q)_\mu \approx s \times (2 - x) \]

(2p_2 - 2q - k)^\alpha \epsilon^\ast_1 \approx 2 \times (q_\perp + k_\perp) \cdot q_\perp \]

(A14)

(A15)

(A16)

Combining these approximations yields

\[ i\mathcal{M}_{3}^{q'\rightarrow qq'g} \approx F_3 \delta_{\mu\nu} \delta_{\omega s'} \frac{2s}{q_\perp^2} \frac{2 - x}{q_\perp s} (q_\perp + k_\perp) \cdot q_\perp \]

(A17)

which is suppressed by \( 1/s \) compared to the other diagrams listed in [10] and thus in the GB approximations justifies setting \( i\mathcal{M}_{3}^{q'\rightarrow qq'g} \approx 0 \).

**Diagram 4**

Diagram 4 is given by

\[ i\mathcal{M}_{4}^{q'\rightarrow qq'g} = \frac{F_4}{q^2(p_1 + k)^2} J_{\mu}^{\nu\rho}(p_3, p_1) g_{\mu\nu} \times \epsilon^\ast_1(k) \]

\[ \approx \frac{F_4}{q^2(p_2 - q)^2} (2p_1 + q)^\mu (2p_2 - q)_\mu \times (2p_2 - k)^\alpha \epsilon^\ast_1(k) \]

(A18)

with \( F_4 = -ig^3 \lambda^a_{\alpha\beta} \lambda^b_{\mu\nu} \delta^{ac} \). Since \( (2p_2 - k)^\alpha \epsilon^\ast_1 = 0 \) without any further approximation, diagram 4 does not contribute.

**Diagram 5**

Diagram 5 that describes the gluon emission off the exchanged gluon is the most tedious one to evaluate.
is given by

\[ iM_{3}^{qg} = \frac{F_5}{q^2 (q - k)^2} J_{\mu_3}^\prime (p_3, p_1) J_{\nu_3}^\prime (p_4, p_2) g_{\mu_3 \nu_3} g_{\mu \nu} \]

\times \epsilon_5^\dagger (k) \left[ g^{\mu \nu} (k - 2q) + g^{\nu \mu} (k + q) \right.

\left. + g^{\nu \mu} (q - 2k) \right]

\[ \simeq \frac{F_5 \delta_{\mu_3 \mu_3} \delta_{\nu_3 \nu_3}}{q^2 (q - k)^2} \left[ A + B + C \right] \quad (A19) \]

with \( F_5 = g^3 f_{abc} \lambda_5^a \lambda_5^b \lambda_5^c \) and

\[ A = \left[ (2p_1 + q - k) \mu (q + k) \right] \left[ (2p_2 - q) \nu \epsilon_5^\dagger \right] \]

\[ \simeq 2 \frac{x^2}{1 - 2x} q_{\perp} \epsilon_\perp \quad (A20) \]

\[ B = \left[ (2p_2 - q) \mu (q - k) \right] \left[ (2p_1 + q - k) \nu \epsilon_5^\dagger \right] \]

\[ \simeq -4 s k_{\perp} \epsilon_\perp \quad (A21) \]

\[ C = \left[ (2p_1 + q - k) \mu (2p_2 - q) \nu \right] \left[ (k - 2q) \epsilon_5^\dagger \right] \]

\[ \simeq 2 s (2 - x) q_{\perp} \epsilon_\perp \quad . \quad (A22) \]

The term \( A \) is not proportional to \( s \) and thus can be neglected in respect to \( B \) and \( C \). Together with the approximations for the propagators, \( q^2 \simeq -q_1^2 \) and

\[ (q - k)^2 \simeq -\left( \frac{q_1 - q_2}{1 - x} \right)^2 \quad , \quad (A23) \]

this leads to the result in Eq. (10) where additionally approximation [6] needs to be employed in collecting the above given terms. The constraint \( x^2 s \gg k_1^2 \) is needed in the computation of diagram 5 when approximating the first term of \( C \) as given in \([A22]\).
